## REPUBLIC.

**R**EPUBLIC, *REPUBLICA*, *commonwealth*, a popular state or government; or a nation where the body, or only a part of the people, have the government in their own hands.

When the body of the people is possessed of the supreme power, this is called a *democracy*. When the supreme power is lodged in the hands of a part of the people, it is then an *aristocracy*. See *ARISTOCRACY* and *DEMOCRACY*.

The celebrated republics of antiquity are those of Athens, Sparta, Rome, and Carthage. At present, there is scarcely any such thing as a real republic, *i. e.* a strictly popular state. Indeed, the Venetians and Genoese have called their states republics; but their government was apparently *oligarchic*.

The Dutch, in their former state, came the nearest to the character of a republic; yet they were very defective, at least in the sense and severity with which Rome, Carthage, &c. were republics. See *STATES-General*.

It is a remark of M. St. Evremont, that if the Dutch love the republican form, it is more for the sake of their trade than of their liberty.

Holland, which was composed of about fifty republics, all different from one another, might be considered as a confederate republic; or a convention by which several petty states agree to become members of a larger one, which they intend to establish. When several sovereign and independent states unite themselves together by a perpetual confederacy, whilst each of them continues to be a perfect state, they will form together a federal republic: the deliberations in common will offer no violence to the sovereignty of each member, though they may, in certain respects, put some constraint on the exercise of it, in virtue of voluntary engagements. A person does not cease to be free and independent when he is obliged to fulfil the engagements into which he has

very willingly entered. In this view, Germany, which consisted of free cities, and of petty states, subject to different princes, and the Swiss cantons, were considered in Europe as perpetual republics.

Of this kind were formerly the cities of Greece; and in later times were the seven United Provinces of the Netherlands; and such, as we have just said, were the members of the Helvetic body. To this class we may likewise refer the federal government of the United States of America. See *GOVERNMENT*.

Baron de Montesquieu, in his "Spirit of Laws," enumerates the following distinctive properties of a republic. It should have a small territory; otherwise it cannot long subsist. In a large republic there are men of large fortunes, and consequently of less moderation; there are too great deposits to intrust into the hands of a single subject; interests are divided; an ambitious person soon becomes sensible that he may be happy, great, and glorious, by oppressing his fellow-citizens; and that he might raise himself to grandeur on the ruins of his country.

In a large republic, the public good is sacrificed to a thousand views; it is subordinate to exceptions; and depends on accidents. In a small one, the interest of the public is easier perceived, better understood, and more within the reach of every citizen; abuses have a lesser extent, and of course are less protected.

The long duration of the republic of Sparta was owing to its having always continued with the same extent of territory after all its wars. The sole aim of Sparta was liberty; and the sole advantage of its liberty, glory.

It was the spirit of the Greek republics to be as contented with their territories, as with their laws. Athens was first fired with ambition, and gave it to Lacedæmon; but it was an ambition rather of commanding a free people, than of governing

governing slaves; rather of directing than of breaking the union. All was lost upon the starting up of monarchy, a government whose spirit is more turned to increase and advancement.

Excepting particular circumstances, as when a petty sovereign supports himself betwixt two great powers by means of their mutual jealousy, it is difficult for any other than a republican government to subsist long in a single town. A prince of so petty a state would naturally endeavour to oppress, because his power would be great, while the means of enjoying it, or of causing it to be respected, would be very inconsiderable. The consequence of this would be, that he would trample upon his people. On the other hand, such a prince might be easily crushed by a foreign, or even a domestic force; the people might every instant unite and rise up against him. Now, as soon as a prince of a single town is expelled, the quarrel is over; but if he has many towns, it only begins.

REPUBLIC of *Letters*, is a phrase used in speaking collectively of the whole body of the people of study and learning.

There is a journal, begun in Holland, by M. Bayle, and continued by M. Bernard, consisting of extracts of books, printed in the course of the year, called "Nouvelles de la Republique des Lettres," News from the Republic of Letters. See JOURNAL.

REPUBLICANISM of a *Will*. See WILL.

REPUDIATION, REPUDIUM, in the *Civil Law*, the act of divorcing. See DIVORCE.

REPULSE BAY, in *Geography*, a bay on the N.E. coast of New Holland, in the South Pacific ocean. S. lat. 20° 36'. W. long. 148° 33'. — Also, a bay on the coast of Kerguelen's land. — Also, a bay on the W. coast of America. N. lat. 66° 40'. W. long. 85°.

REPULSION, REPULSION, in *Physics*, the act of a repelling power, by which bodies, under certain circumstances, naturally fly from each other.

Repulsion is the counter part to *attraction*. Attraction only reaches to a little distance; where that terminates, there repulsion commences. See AIR and COMPRESSION.

Indeed, we meet with many obvious instances of repulsion among bodies, as between water and oil, and, in general, between water and all unctuous bodies; between mercury and iron, as also between the particles of dust, &c.

Thus, if a fat body, lighter than water, be laid on the surface of it, or if a piece of iron be laid on mercury, the surface of the fluid will be depressed about the bodies laid on it. This is a plain indication of repulsion; as the rising up of the fluid about the surfaces of other incumbent bodies is of attraction.

In the latter case, the fluid is suspended, by an attractive power, above the level, and kept from falling by its gravity: in the former, a depression is made by the repelling power, which the liquor, notwithstanding its gravity, cannot run down into, and fill up.

Upon this depend all the phenomena of very light glass bubbles floating on water, about which, when clean, the water rises; but when greased, the water sinks into a channel all around them. Hence also it is, that in a glass-vessel of water, the fluid stands higher all about the edges near the glass than towards the middle; but when the glass is filled till the water run down on all sides, then it stands higher at the middle than at the sides. Hence, also, in a glass not full of water, a clean glass bubble always runs to the side, by reason the pressure, which is upon it towards the middle, is partly taken off by the attractive force with which the water is raised near the edge.

If the glass be so full as to be ready to run over, the bubble returns from the side towards the middle, the force with which the water is raised in the middle taking off part of the pressure.

Just the reverse happens if the bubble be greasy; because there the force, by which the water and the bubble repel each other, is greatest where the water is highest. Two clean bubbles and two greasy ones always run towards each other, as being attracted; and a greasy and a clean one always fly each other, as being repelled.

REPUTATION, *Injuries affecting*. See INJURY.

REQUENA, in *Geography*, a town of Spain, in New Castile, seated on the top of a hill, near the Ollana, on the borders of Valencia. Bourgoanne, a modern traveller, says, that wealth and activity proclaim in this place the presence of industry, and accordingly the number of silk looms amounts to 900. It has been supposed to be the Salaria, placed by Ptolemy in the country of the Bastitani; 55 miles S.E. of Cuenca.

REQUEST, in *Law*, a supplication or petition preferred to a prince, or court of justice, begging relief in some conscientious cases, where the common law grants no immediate redress.

The term request is now, since the institution of chancery, much disused; together with the court of requests, where requests were cognizable.

In the old government of France, *requêtes civiles*, civil requests, obtained for the annulling of contracts, &c. made by surprize.

They had eighty masters of requests to take cognizance of causes between the officers of the crown, the servants of the household, &c.

REQUESTS, *Court of*. See COURT of *Requests*, and COURT of *Conscience*.

REQUEST, in *Hunting*, is when the dogs have lost the quest or track of the beat, and must *request*, or *quest* it again. They say, *to call to the request, come to the request, &c.*

To request the game is chiefly used, when, after having run it down the night before, they seek it again the next morning with the blood-hound, or the like.

REQUEURIA, in *Botany*, a genus named in the Flora Peruviana, page 16, after Louis Requeur, a Spaniard, who was apothecary to king Philip V. *De Theis*. We are unacquainted with the plant, as well as with the botanical merits of the person to whom it is dedicated.

REQUIEM, a mass sung in the Romish church for the rest of the soul of a person deceased.

It is thus called, because the introit begins with "Requiem æternam dona eis, Domine," &c.

REQUINY, in *Geography*, a town of France, in the department of the Morbihan; 6 miles N.W. of Joffelin.

REQUISTA, a town of France, in the department of the Aveiron; 18 miles S. of Rhodéz.

RERE COUNTY. See RIER County.

RERE *Fiefs*, a name given in the Scotch laws to those fiefs which were held by inferior tenants or feudatories, that cultivated the lands under the chief feudatories, who held by military service.

RERE *Ward, arriere-garde*. See REAR, and GUARD.

REREDOS, the screen at the back of an ancient high altar, which separated it from the Lady-chapel, being, for the most part, highly ornamented with niches, canopies, and tracery work. The richest of these which have reached our time are those of Winchester and Durham cathedrals, and of St. Alban's abbey.

RERHUTTAN, in *Geography*, a town of Sweden, in Dalecarlia; 30 miles S.W. of Gessle.

**RERIGONIAN BAY**, in *Ancient Geography*, a bay on the northern side of ancient Britain, now Loch-rain, formed by the Mull of Galloway.

**RERIGONIUM**, called by some *Berigonium*, a town of the Novantæ, situated somewhere in Galloway, according to Camden the present Bargeny in Carriët; but Horsley prefers Barton or Strathaven.

**RERONE**, in *Geography*, a river of Italy, which rises in the Vicentin, and runs into the Brenta.

**RERRE**, a river of France, which runs into the Saudre, about a league above Romorantin.

**RES**, *Thing*. See REALITY, ENS, ESSE, SUBSTANCE, &c.

**RES Mancipi**. See ABALIENATION.

**RES Naturales**. See NATURALS.

**RES Non Naturales**, &c. See NON-naturals, &c.

**RESAFA**, in *Ancient Geography*, a town of Asia, on the W. side of the Euphrates.

**RESAIA**, a town of Mesopotamia, in Osrhoenë.

**RESAINA**, or THEODOSIOPOLIS, *Ras-vin*, or *Ain-verdab*, a town of Mesopotamia, upon the banks of the river Chabotas. This town was famous on account of the victory obtained over Sapor by the younger Gordian, in the year 243. Under the empire of Severus, it was elevated to the dignity of a colony; and under Theodosius it assumed the name of Theodosiopolis.

**RESAPHE**, a town of Palmyrene, according to Ptolemy; but Procopius called it Sergiopolis. It was at some distance from the Euphrates.

**RESAU** or REHAU, in *Geography*, a town of Germany, in the principality of Culmbach; 7 miles E.S.E. of Hoff.

**RESAVA**, a river of Servia, which runs into the Passarowitz.

**RESCUIT**, **RECEPTIO**, in *Law*, an admission or receiving of a third person to plead his right, in a cause formerly commenced between other two.

As, when an action is brought against a tenant for life or years, and he makes default; in such case he in the reversion may come in and pray to be received, to defend the land, and to plead with the demandant.

**RESCUIT** is also sometimes applied to an admittance of plea, though the controversy be only between two. He in reversion may come into court, and pray to be received in a suit against his particular tenant.

**RESCUIT** of homage, *receptio homagii*, denotes the lord's receiving homage of his tenant, at his admission to the lands.

**RESCHOUET**, in *Geography*, a town of Prussia, in Pomerelia; 7 miles N.N.E. of Zarnowitz.

**RESCIPHA**, in *Ancient Geography*, a place of Mesopotamia, on the banks of the Euphrates; situated S. of Corfote, and near to it.

**RESCISSIO**, **RESCISSIO**, formed of *re*, and *scindo*, *q. d. I cut or divide again*, in the *Civil Law*, an action intended for the annulling or setting aside of any deed, contract, or the like.

A thing's being found damaged, or sold at above double the just value, is a good cause of rescission.

The deed or contract thus annulled, or rescinded, is sometimes called a *rescissory*; though that denomination be more properly given to the action brought for rescinding or setting it aside; which is properly called *actio rescissoria*.

**RESCOUS**, or **RESCUE**, *Rescussus*, in *Law*, an illegal taking away, and setting at liberty, a distress taken, or a person arrested, by process, or course of law. This is properly a *rescous* in fact. If one distrain beasts for damage feasant in his ground, and as he drives them along the highway towards the pound, they enter into the owner's house, and he withholds them there, and will not deliver them upon demand; this detainer is a *rescous*

in law. For a rescous, or the taking of goods by force, when, in a distress, they are in the custody of the law, which is considered as an atrocious injury, the distresser has a remedy in damages, either by writ of *rescous* (F. N. B. 101.), in case they were going to the pound, or by writ of *de parco fraudo*, or pound-breach (ibid. 100.) in case they were actually impounded. He may also at his option bring an action on the case for this injury, and shall therein, if the distress were taken for rent, recover treble damages. (Stat. 2 W. & M. sess. 1. c. 5.) In case of the forcible delivery of a person arrested from the officer who is taking him to prison, the plaintiff has a similar remedy by action on the case, or of rescous (6 Mod. 201.); or, if the sheriff makes a return to such rescous to the court out of which the process issued, the rescuer will be punished by attachment. Cro. Jac. 419. Salk. 586. See **RESCUE**. He that commits a rescue or rescous, is called the *rescissor*.

**RESCOUS** is also used for a writ which lies for this fact, called *breve de rescussu*.

**RESRIPT**, **RESRIPTUM**, an answer delivered by an emperor, or a pope, when consulted by particular persons, on some difficult question or point of law, to serve as a decision of it.

The civil and canon laws are full of such rescripts.

When the rescript was made in answer to the enquiry of a community, it was called a *pragmatic sanction*.

The papal rescripts are a kind of bulls or monitories, beginning with these words, "Significabit nobis dilectus filius," &c. They never obtained either in England or France, when contrary to the liberties of the English and Gallican churches; but were declared abusive.

Among the Romans the contending parties and even the magistrates themselves, frequently consulted the emperor on the measures they were to take in certain and nice difficult cases; and the answers returned by the emperor on such consultations, were called *rescripts*. These had not, indeed, the full force of laws; but they were deemed a strong prejudice or presumption: and in succeeding ages, they had the force of perpetual laws, though they ought to be carefully distinguished, by every rational civilian, from those general constitutions which had only the nature of things for their guides.

Justinian has inserted a great number of them in the Code; and by that means given them the authority they before wanted.

The author of the life of the emperor Macrinus observes of that prince, that he would have his officers judge by laws, not by rescripts; as esteeming it absurd to admit the wills of ignorant men, such as Commodus and Caracalla, for rules of judging; and because Trajan never gave any rescripts at all, as being loth to countenance a custom, where what is frequently granted as a favour, in particular cases, might be afterwards pleaded as a precedent. It is added, that Macrinus had a design to strip the rescripts of all their authority.

M. Schulting, in his Dissertations, does not at all approve of this design; and to the emperor's reasons answers, that indeed all rescripts are not to be admitted; that those which appear dictated out of favour, are to be thrown aside; but those which appear founded in reason, and natural equity, are, with Justinian, to be allowed. He adds, that it cannot be denied but the worst emperors have frequently made good laws, and useful rescripts.

As to what is urged of the emperor Trajan's never giving any rescripts, it appears but ill supported. For what is it but a rescript that he delivers to Pliny on the subject of the Christians, lib. x. epist. 28? Or that on the Isesticæ, lib. x. epist. 120? The Digest, and Pliny's Epistles, need

only to be opened and compared, to find rescripts of Trajan. The rescripts of the emperor, his grants and decrees, his edicts and pragmatic sanctions, were subscribed in purple ink, or a compound of vermilion and cinnabar; and transmitted to the provinces as general or special laws, which the magistrates were bound to execute, and the people to obey. But as their number continually multiplied, the rule of obedience became each day more doubtful and obscure, till the will of the sovereign was fixed and ascertained in the Gregorian, Hermogenian, and the Theodosian codes.

**RESCUE.** See **RESCOUS.** See also **DISTRESS,** and **DISSEISIN.**

**RESCUE** is one of those offences against public justice, which consists in the forcibly and knowingly freeing another from an arrest or imprisonment; and it is generally the same offence in the stranger so rescuing, as it would have been in a gaoler to have *voluntarily* permitted an escape. A rescue, therefore, of one apprehended for felony, is felony; for treason, treason; and for a misdemeanour, a misdemeanour also. But here likewise, as upon voluntary escapes, the principal must first be attainted, or receive judgment before the rescuer can be punished: and for the same reason; because perhaps in fact it may turn out that there has been no offence committed. By statute 11 Geo. II. c. 26. and 24 Geo. II. c. 40. if five or more persons assemble to rescue any retailers of spirituous liquors, or to assault the informers against them, it is felony, and subject to transportation for seven years. By the statute 16 Geo. II. c. 31, to convey to any prisoner in custody for treason or felony any arms, instruments of escape, or disguise, without the knowledge of the gaoler, though no escape be attempted, or any way to assist such prisoner to attempt an escape, though no escape be actually made, is felony, and subjects the offender to transportation for seven years: or if the prisoner be in custody for petit larceny, or other inferior offence, or charged with a debt of 100*l.*, it is then a misdemeanour, punishable with fine and imprisonment. And by several special statutes, to rescue, or attempt to rescue, any person committed for the offences enumerated in those acts, is felony without benefit of clergy; and to rescue, or attempt to rescue, the body of a felon executed for murder, is single felony, and subject to transportation for seven years. Nay, even if any person be charged with any of the offences against the black act, 9 Geo. I. c. 22, and, being required by order of the privy council to surrender himself, neglects so to do for forty days, both he and all that knowingly conceal, aid, abet, or succour him, are felons without benefit of clergy. See **CONTEMPT.**

**RESCUSSOR,** in *Law.* See **RESCOUS.**

**RESA,** or **REZE,** in *Geography,* a town of France, which runs into the Sindre, at Romorantin.

**RESEARCH,** formed of the French, *recherche,* and literally denoting a *second search,* a diligent search or enquiry into any thing.

**RESEARCH,** in *Music,* is a kind of prelude or voluntary played on the organ, harpsichord, violin, &c. in which the composer seems to *search* or look out for the strains and touches of harmony, which he is to use in the regular piece to be played afterwards.

This is usually done off-hand; and consequently it requires a master's skill. When in a motetto, the composer takes the liberty to use any thing that comes into his head, without applying any words to it, or subjecting himself to the sense or passion of it, the Italians call it *fantasia ricercata,* the French *recherche,* and the English *research* and *voluntary.*

**RESEARCHING,** in *Sculpture,* the repairing of a cast, figure, &c. with proper tools; or the finishing it with art and exactness, so as that the minutest parts may be well defined.

**RESEDA,** in *Botany,* a name which occurs in Pliny, and is evidently derived from *resēdo,* to allay or mitigate; so that the second syllable, vulgarly pronounced short, ought to be long. Pliny reports that this herb is known in the neighbourhood of Rimini, and is used for dispersing tumours, and all kinds of inflammations. The person who applies the medicine, says "Reseda allay these diseases," repeating these words, with some others, and spitting as often. After this account, the reader may not be anxious to know what Pliny's *Reseda* was. We have certainly no more reason to believe it the same as our's, than we have to rely on his sapient prescription.—Linn. Gen. 242. Schreb. 326. Willd. Sp. Pl. v. 2. 876. Mart. Mill. Dict. v. 4. Sm. Fl. Brit. 512. Prodr. Fl. Græc. Sibth. v. 1. 322. Ait. Hort. Kew. v. 3. 153. Juss. 245. Tourn. t. 238. Lamarck Illustr. t. 410. Gært. t. 76. (*Luteola*; Tourn. t. 238. *Sesamoides*; Tourn. t. 238.)—Class and order, *Dodecandria Trigynia.* Nat. Ord. *Miscellanea,* Linn. *Caparides,* Juss.

Gen. Ch. Cal. Perianth inferior, of one leaf, deeply divided into narrow, erect, permanent segments, two of which are further asunder than the rest, for the accommodation of the honey-bearing petal. Cor. Petals several, unequal; some of them always cut half way down into three segments; the upper one gibbous at the base, bearing honey, the length of the calyx. Nectary a flat erect gland, proceeding from the receptacle, situated at the upper side of the flower, between the stamens and uppermost petal, converging with the dilated base of the petals. Stam. Filaments eleven or fifteen, short; anthers erect, obtuse, the length of the corolla. Pist. Germen gibbous, ending in three or four very short styles; stigmas simple. Peric. Capsule gibbous, angular, coriaceous, tipped with the styles, and gaping at the summit between them, of one cell. Seeds numerous, kidney-shaped, inserted into the angles of the capsule.

Obs. Linnæus observes, that there is scarcely any genus whose character is more difficult to determine, both the number and shape of the parts being different in different species. The essential character consists in the three-cleft petals, one petal bearing honey at its base, and the capsule not being closed, but always gaping.

*R. Luteola* has the perianth in four deep segments; petals three, the upper, or honey-bearing one, cut half way down into six segments; the lateral ones opposite, three-cleft; to which are often subjoined, by nature or luxuriance, two more, very small, undivided petals; the styles are three: stamens numerous.

*R. alba* has six deep segments in the perianth: petals six, nearly equal, all of them half three-cleft; styles four; capsule with four angles; stamens constantly eleven.

Some other species have a deeply five-cleft perianth; five dissimilar three-cleft petals; styles three; stamens numerous.

Ess. Ch. Calyx of one leaf, deeply divided. Petals lacinated. Capsule superior, gaping at the top, of one cell, with many seeds.

1. *R. Luteola.* Dyer's-weed, Yellow-weed, or Weld. Linn. Sp. Pl. 643. Willd. n. 1. Ait. n. 1. Fl. Brit. n. 1. Engl. Bot. t. 320. Mart. Ruft. t. 40. (*Luteola*; Ger. Em. 494. *Pseudostruthium*; Matth. Valgr. v. 2. 643.)—Leaves lanceolate, undivided, flat. Calyx four-cleft.—Native of waste ground, rubbish, banks, and old walls, chiefly about villages, in most of the temperate parts of Europe. About Norwich it is very common; partly perhaps from the dispersion of its seeds, in consequence of the great use made of the cultivated herb, in the woollen manufactory of that city, for dyeing yellow. The colour it affords is very bright, and is especially useful for making a good

a good green; the cloth being first dyed blue. The herb is annual, flowering in July. Root spindle-shaped. Stem erect, wand-like, two or three feet high, branched, leafy, striated, smooth. Leaves linear-lanceolate, entire, smooth, for the most part furnished with a small callous tooth, on each side, at the base. Flowers small, cream-coloured, very numerous, in long, simple, solitary, terminal, slightly drooping spikes, which, according to Linnæus, follow the course of the sun, even in a cloudy day—

“ True, as the dial, to the sun,  
Although it be not shined upon.”

2. *R. canescens*. Hoary Base Rocket. Linn. Syst. Nat. ed. 12. v. 2. 330. Willd. n. 2. Ait. n. 2? Vahl. Symb. v. 2. 52. (*R. hexagyna*; Forsk. Ægypt-Arab. 92. *Sefamoides salmanticum parvum alterum*; Cluf. Hist. v. 1. 296, no figure. S. flore albo, foliis canescentibus; Tourn. Infl. 424.)—Leaves lanceolate, waved, somewhat hairy. Branches hispid.—Native of waste ground near Cairo. Forskall. Probably also of the south of Europe. The stems are decumbent, branched, eighteen inches or more in length, round, leafy, rough with copious, minute, white, spreading, short, brittle hairs. Leaves scattered, lanceolate, one and a half or two inches long, bluntish, entire, wavy, and roughish at the edges, as well as at the midrib on both sides; otherwise smooth, and somewhat glaucous; tapering at the base, and sending down two elevated ribs, for some distance, along the branch. Flowers in long, terminal, stalked, hairy clusters, on short partial stalks. Calyx five-cleft. Petals white. Germen, according to Forskall's description, stalked, with six styles.—Vahl has well remarked that *R. canescens* of Sp. Pl. cannot be the same with the above. Indeed it appears to be no other than either *R. sesamoides* or *purpurascens*, the figure of Clusius agreeing best with the former; his description and the Linnæan definition with the latter. Yet this same figure, adopted by Gerarde, seems to be the only foundation on which *R. canescens* depends for a place in Hort. Kew.—We have never seen the true *canescens* living, nor can we find a figure of it.

3. *R. glauca*. Glaucous Base Rocket. Linn. Sp. Pl. 644. Willd. n. 3. Ait. n. 3. (*R. linariæ foliis*; Bauh. Prodr. 42, no figure. *Sefamoides linariæ folio glauco, pyrenaica, flore stamineo*; Morif. sect. 15. t. 1. f. 4.—Leaves linear; toothed at the base. Styles four.—Native of the Pyrenean mountains; according to Burser's herbarium, examined by Linnæus. Gathered also by Læfing, in Spain. The root is said to be perennial, but has the appearance of being annual. Whole herb glaucous, slender, and smooth. Stem twelve or eighteen inches high, simple, round, wand-like, leafy. Leaves about two inches long, very narrow; all nearly of equal breadth, furnished at the base with a few white brittle teeth. Cluster terminal, solitary, very long, of numerous white flowers, whose petals are less divided than in most other species.

4. *R. dipetala*. Flax-leaved Base Rocket. Ait. n. 4. Willd. n. 4. Vahl. Symb. v. 2. 52. (*R. capensis*; Barm. Prodr. 13.)—Leaves linear, entire. Styles four. Petals two, undivided.—Native of the Cape of Good Hope, from whence its seeds were sent to Kew, in 1774, by Mr. Masson. The plant is biennial, flowering in August, being preserved in a greenhouse through the winter. Vahl compares its general aspect to *R. Sefamoides*, hereafter described. Stem somewhat shrubby, erect, with round branches. Leaves about an inch long, rather fleshy, smooth. Cluster terminal, lax. Segments of the calyx six, minute, bordered with white. Petals only two, wedge-shaped, undivided.

5. *R. purpurascens*. Purplish Base Rocket. Linn. Sp. Pl. 644. Willd. n. 5. (*Sefamoides salmanticum parvum*

*primum*; Cluf. Hist. v. 1. 296, excluding the figure. S. foliis crassis, floribus ex herbaceo purpurascens; Tourn. Infl. 424.)—Leaves linear, obtuse. Styles five.—Native of Spain. Læfing.—Stems several, a span high, simple, leafy. Leaves scattered, the length of the nail, linear, obtuse, smooth. Cluster, or rather spike, long, lax. Petals very white, much divided. Styles five, sometimes, as Clusius describes them, only four. Capsule with as many protuberant, single-seeded, knobs or pouches.

6. *R. Sefamoides*. Spear-leaved Base Rocket. Linn. Sp. Pl. 644. Willd. n. 6. Ait. n. 5. (*Sefamoides parvum salmanticum*; Cluf. Hist. v. 1. 295, the figure only. Ger. Em. 493. Lob. Ic. 353.)—Stem-leaves linear-lanceolate, obtuse, radical ones lanceolate, stalked, much larger. Fruit flattened.—Native of Barbary, and the south of Europe. A hardy annual in Kew garden; flowering in July and August. The root is spindle-shaped, very long, tapering, and branched at the extremity. Stems numerous, spreading nearly horizontally, from three to twelve inches long, generally simple, smooth, leafy. Radical-leaves numerous, lanceolate or somewhat obovate, entire, smooth, an inch long, tapering down into a footstalk of about the same length; stem-leaves much smaller and narrower, linear, and obtuse. Clusters terminal, rather dense. Petals white. Styles four or five. Capsule of the same number of spreading lobes, fringed at the edges, and assuming a star-like figure.—The wooden cut of Clusius so exactly represents this plant, especially the radical leaves, that we can take it for no other. Allioni's plate, t. 88. f. 3, does not accord with this, or any other *Reseda* known to us, except having a general resemblance to *canescens*, n. 2, without its roughness, or the undulations of its leaves.

7. *R. fruticulosa*. Shrubby Base Rocket. Linn. Sp. Pl. 645. Willd. n. 7. Ait. n. 6. Jacq. Coll. v. 3. 195. Ic. Rar. t. 474.—Leaves pinnate. Stem shrubby in the lower part. Styles three or four. Petals all three-cleft. Calyx in five spreading segments.—Native of Spain, and other parts of the south of Europe. John Symmons, esq. is recorded by Mr. Aiton as having introduced it into England, in 1794. The root, and base of the stem, are woody and perennial, producing a number of upright, less durable, branches, two or three feet high, leafy, subdivided, smooth, round, with elevated ribs. Leaves alternate, stalked, pinnate, of five, seven, or many more, lanceolate, entire, decurrent, smooth leaflets, seldom regularly opposite; the terminal one much the largest, sometimes, but not always, recurved at the point; the lower ones gradually smallest. Clusters terminal, erect, long, and rather lax. Petals five, white, uniform, oblong, all cut, not nearly half way down, into three equal segments. Styles often four; sometimes but three. Stamens eleven. Linnæus thought it an intermediate species between *alba* and *undata*. From the first of these it is very distinct. By an accidental error in Sp. Pl. the present species is there called *suffruticulosa*, which has led to the same inaccuracy in the Prodr. Fl. Græc. n. 1092. The name is correct in Herb. Linn.

8. *R. alba*. White Base Rocket, or Upright Mignonne. Linn. Sp. Pl. 645. Willd. n. 8. Ait. n. 7. Sm. Tj. Græc. Sibth. t. 459, unpublished. (*R. maxima*; Bauh. Pin. 100. Lob. Ic. 222. Ger. Em. 277.)—Leaves pinnate. Stem erect, branched. Styles three or four. Petals unequally and deeply five-cleft. Calyx in five spreading segments.—Native of Spain and the south of France; as well as of Greece and the island of Zante. It has been cultivated in our gardens ever since the days of Gerarde, being a hardy annual or biennial, ornamented, throughout the summer, with copious dense spikes, of elegant white flowers, whose petals have deeper, more numer-

ous segments, than the foregoing. Otherwise their parts of fructification do not much differ. The number of *styles*, and of segments of the *calyx*, varies in both, according to luxuriance. The *leaflets* of *alba* are more numerous, as well as more equal in size, than in *fruticulosa*, nor is the terminal one larger than the rest. Sometimes their edges are roughish. Dr. Sibthorp observed, that the whole herb, and also the bruised seed, were used in Zante to dye silk yellow.

9. *R. undata*. Wave-leaved Base Rocket. Linn. Sp. Pl. 644. Willd. n. 9. Ait. n. 8. (*R. decursiva*; Forfk. Ægypt-Arab. cat. 66. *R. minor alba, dentatis foliis*; Barrel. Ic. t. 588.)—Leaves pinnate, wavy. Styles three to five. Petals unequally cut.—Native of Spain. Cultivated by Miller, at Chelsea, in 1739. A hardy perennial, flowering in summer. The *stems* are erect, branched, straight and wand-like, one to two feet high. *Leaves* unequally pinnate, very much crisped, or wavy. *Flowers* smaller than in either of the last, and of a less pure white, composing very long *clusters*, or rather *spikes*, for each flower is nearly sessile; the lower ones very remote. Some of the *petals* appear, by the dried specimens, to have three, others five, obtuse segments, of which the lateral ones are broadest. We have great doubts, whether the specimen from which Linnæus took his remark of the great size of the *capsules*, really belongs to this species.

10. *R. lutea*. Yellow Base Rocket, or Wild Mignonette. Linn. Sp. Pl. 645. Willd. n. 10. Ait. n. 9. Fl. Brit. n. 2. Engl. Bot. t. 321. Jacq. Austr. t. 353. Bulliard. t. 281. (*R. Plinii*; Ger. Em. 277.)—All the leaves three-cleft; the lower ones pinnate. Petals six, very unequal. Calyx in six segments.—Native of dry chalky hills in the temperate and southern countries of Europe; abundant in the chalky parts of England, flowering from June to the end of autumn. The *root*, generally annual with us, often survives a mild winter. *Stems* spreading, branched, leafy, a foot or more in height. *Leaves* tapering at the base; some of them with only one pair of lateral leaflets; others with many, which are occasionally subdivided; all the leaflets, or segments, are linear, channelled, more or less wavy; frequently very much crisped or curled. Such is the variety, mentioned as a species, by Dillenius, in Raii Syn. 366, as *R. crispa gallica*, Bocc. Sic. 77. t. 41. f. 3; but we have often suspected, that Boccone's plant might be the *undata*. It is hazardous, however, to depend much on such imperfect materials as he affords. The *flowers* are numerous, sulphur-coloured, slightly, and not agreeably, odorous; their two upper petals with two fan-like lateral lobes, and a short linear one between; two lateral petals very unequally and variously three-cleft; two lower ones narrow, and almost simple.

11. *R. Phyteuma*. Scentless Mignonette. Linn. Sp. Pl. 645. Willd. n. 11. Ait. n. 10. Jacq. Austr. t. 132. (*Reseda affinis Phyteuma*; Bauh. Prodr. 42. *Erucago apula, trifida et quinquefolia*; Column. Ecephr. 267. t. 269. f. 2.)—Leaves undivided, or three-lobed. Calyx in six, very large, obovate segments. Petals four, more or less pectinated.—Native of the south of Europe and north of Africa. On the walls of Rome it is very common, and having a general resemblance, without the fragrance, of our garden mignonette, it has given rise to a report of that charming flower being destitute of scent in Italy! Miller cultivated *R. Phyteuma* at Chelsea, where it still springs up annually in the garden. The *root* is long and tapering. *Stems* very numerous, a span high, composing a large spreading tuft. *Leaves* broadish, tapering at the base; some of them simply obovate; others with a pair of lateral lobes. *Flowers* cream-coloured, in lax simple clusters. *Calyx* very much enlarged, and reflexed, after flowering.

*Petals* four; the lower pair, in particular, elegantly pectinated at one side; but all of them are liable to vary, in the number and depth of their segments. *Fruit* pendulous, obovate, angular. *Styles* three.

12. *R. mediterranea*. Mediterranean Mignonette. Linn. Mant. 564. Willd. n. 12. Ait. n. 11. Jacq. Coll. v. 1. 147. Ic. Rar. t. 475.—Leaves flat, undivided, or three-lobed. Calyx much shorter than the corolla. Petals six, very unequal.—Native of Palestine, according to Linnæus, who received it from Schreber. Dr. Sibthorp met with it in corn fields in the islands of the Archipelago. This is a hardy annual, flowering all summer long, agreeing very much in appearance with the last, but still more with the following. The *flowers* have no scent. Their *petals* are six, most resembling those of *R. lutea* in figure, but white, not yellow. The *leaves* are broader, and less divided, than in *lutea*, as well as quite flat; they vary however greatly in breadth, but are never undulated. The *calyx* is short, never enlarged like that of *R. Phyteuma*.

13. *R. odorata*. Sweet Mignonette. Linn. Sp. Pl. 646. Willd. n. 13. Ait. n. 12. Mill. Ic. t. 217. Curt. Mag. t. 29.—Leaves flat; undivided, or three-lobed. Calyx equal to the corolla. Segments of the petals all very deep, somewhat spatulate.—Native of Egypt. Well known throughout the gardens of Europe, as a hardy annual, blooming all the year round, if properly sheltered, and exhaling from its neat unobtrusive flowers, a most delicious scent, resembling that of the vine-blossom, or the fruit of the raspberry. This odour remains long in wooden boxes, where the flowers are dried. The *petals* are of a pale buff, prettily contrasted with the red anthers, and, as Jacquin observes, in describing the last, they differ from that in their uniform, long, wedge-shaped, or spatulate segments.

RESEDA, in Gardening, contains a plant of the flowering sweet-scented kind, of which the species cultivated is, the sweet reseda, or mignonette (*R. odorata*).

Mr. Curtis observes, that the luxury of the pleasure-garden is greatly heightened by the delightful odour which this plant diffuses; and as it grows more readily in pots, its fragrance may be conveyed into the house: its perfume, though not so refreshing perhaps as that of the sweet-briar, is not apt to offend the most delicate olfactories.

*Method of Culture*.—This is raised from seed, which should be sown on a moderate hot-bed in March, and when the plants are strong enough to transplant, be pricked out upon another moderate hot-bed to bring them forward, having a large share of air in warm weather, to prevent their drawing up weak. Or they may be sown in pots of light mould, and plunged in the hot-bed, which is probably the better practice. In the first mode, about the end of May the plants may be planted out, some into pots, to place in or near the apartments, and others into warm borders, where they may remain to flower and seed. The plants which grow in the full ground, often produce more seeds than those which are in pots; but at the time when the seed-vessels begin to swell, the plants are frequently apt to be infested with green caterpillars, which, if they are not destroyed, eat off all the seed-vessels.

And when the seeds are sown on a bed of light earth in April, the plants come up very well; and when not transplanted, grow larger than those which are raised in the hot-bed; but they do not flower so early, and in cold seasons scarcely ripen their seeds. In a warm dry border, however, the seeds often come up spontaneously, and grow very luxuriantly; but to have the flowers early in spring, the seeds should be sown in pots in autumn, being kept in frames through the winter, or on a gentle hot-bed in spring. The plants may also be preserved through the winter in a greenhouse, where they

they continue flowering most part of the year, but the second year they are not so vigorous as in the first.

It is cultivated for the fine fragrant smell which it affords, when pots of it are set about the house.

The seed becomes ripe in the beginning of the autumn, when it should be carefully collected in a dry season, and put by in a dry place for future use, after having been properly cleaned.

RESEISER, RESEISIRE, in *Law*, a taking of lands into the king's hands, where a general delivery, or ouster le main, was formerly misused, contrary to order of law.

RESELE, in *Geography*, a town of Sweden, in Angermannland; 55 miles N.N.E. of Hernofand.

RESEMBLANCE. See SIMILITUDE.

RESENIUS, JOHN PAUL, in *Biography*, a Danish bishop and writer, was born at Resen in 1561. He studied at various schools, and in 1583 became subdirector of that at Viborg. Some time after he travelled into foreign countries, took a degree at Wittemberg, and returned to Denmark in 1591. He was afterwards appointed professor of logic and theology in the university of Copenhagen, and received orders to accompany Christian IV., who proposed a visit to England to see his relation, king James. In consequence of another royal mandate, he undertook to translate the whole of the scriptures into Danish. He completed the New Testament first, which he published in two vols. 12mo. in 1605, and the Old Testament followed in 1607. This version of the bible gave rise, in 1609, to a controversy between Resenius and Ivarus Stubæus, professor of Hebrew at Copenhagen, the result of which was, that Stubæus was displaced from his office. In 1614 he was involved in another dispute with Olaf Coccius, the clergyman of Nicolas' church, Copenhagen, which ended in the disgrace and banishment of his opponent. Resenius was raised to the episcopal chair. He died in 1638, and bequeathed upwards of 5000 dollars to charitable purposes. He was author of many works, chiefly on subjects connected with theology. Gen. Biog.

RESENIUS, PETER, counsellor of state in Denmark, was born at Copenhagen in 1625, and in 1646 he went to Leyden, where he applied himself to the study of jurisprudence and the belles lettres during the space of four years, and then made a tour to France, Spain, and Italy. He took the degree of L.L.D. at Padua, and then returned to Copenhagen, where he married in 1655, and two years after was appointed professor of moral philosophy. In 1680 he was ennobled, and in 1684 was nominated a counsellor of state. This learned man died in 1688, and bequeathed a large sum of money, and a very valuable library, to the university of Copenhagen. He was author of a great number of works, the titles of which are enumerated in the General Biography.

RESENTMENT is a lesser degree of wrath, which is violent and permanent anger, and is excited by smaller offences, or by offences committed against less irritable minds: it is a deep reflective displeasure against the conduct of the offender. Indignation is a resentment against a conduct that appears peculiarly unworthy:—some atrocious violation of the principles of gratitude, or something which appears peculiarly despicable and base. Resentment is chiefly excited by some personal offence against the laws of social intercourse, of friendship, or of gratitude, and may terminate in indifference, and, in weak minds, in malice; but it is usually appeased by concessions and acknowledgments.

RESERVATION, RESERVATIO, in *Law*, an action or clause by which something is reserved, *i. e.* is retained, kept, or secured to one's self.

Thus, when a man lets his land, he reserves a rent to be paid to himself for his maintenance, &c.

William the Conqueror, getting all the lands of England, except those belonging to the church and religious houses, into his hands by right of conquest, bestowed a great part of them among his followers, reserving some retribution of rents and services to him and his heirs; which reservation is now, as it was before the Conquest, called the tenure of the lands.

Sometimes reservation signifies as much as an exception; as, when a man lets a house, and reserves to himself one room, that room is excepted out of the demise.

RESERVATION, *Mental*, is a proposition, which, strictly taken, and according to the natural import of the terms, is false; but if qualified with something reserved or concealed in the mind, becomes true.

Mental reservations are the great refuge of religious hypocrites, who use them to accommodate their consciences with their interests. The Jesuits are zealous advocates for mental reservations; yet are they strictly all real liars, as including an intention to deceive.

RESERVATORY. See RESERVOIR.

RESERVE, in *Law*, the same with *reservation*; which fee.

Benefices are sometimes resigned with reserve of a pension. By the canon law, no person may reserve to himself a pension out of a benefice, unless he hath served it ten years.

In the Romish church the ordinary priests have only a power to absolve, in reserve of certain cases, hence called *reserved cases*, as being reserved to the bishop.

The court reserves the cognizance of such an affair to itself. The lawyers say, that no prince ever granted such a power by his letters or patents, but that he reserves to himself a greater.

RESERVE, *body of, corps de reserve*, in *War*. See BODY OF RESERVE.

RESERVE Guard denotes the same as a *picquet* guard, except that the one mounts at troop-beating, and the other at retreat-beating. See GUARD.

RESERVED CASES. See CASES.

RESERVOIR, a large pond or pen of water, artificially made, in order to retain and collect it for the use of canals, rivers, mills, &c. See BASON and CANAL.

The reservoir in a building is a large bason, usually of wood, lined with lead, where water is kept to supply the occasions of the house. At Cannons, the late noble seat of the duke of Chandois, there was a very large reservoir at the top of the house, to which the water was raised by a curious engine, contrived for the purpose. This reservoir was of such capacity, as that, besides supplying all parts of the house by means of pipes and cocks, it likewise turned a mill.

The reservoir is sometimes also a large bason of strong masonry, clayed or paved at the bottom, where the water is reserved to feed jets d'eau, or spouting fountains.

Such is that large one on the top of Marley, called *tron d'enfer, hell mouth*, whose surface, Daviler tells us, contains fifty acres, and its depth such as to contain a hundred thousand cubic fathom of water.

Reservoirs are of great use in collecting and preserving the urine or other liquid matters discharged from the sheds or stables where cattle or other animals are kept, for the purpose of manure, and should of course be formed on all farm-yards. See FARM-YARD.

Such a reservoir is conceived to be essential, even where there are no lands proper for being overflowed by the contents of it, particularly where care is taken to supply it occasionally with a bottom of some good rich earthy matter,

to be imbued with the rich particles of the more heavy substances which are let fall during the stagnant state of the liquid. This matter should be carried out in a dry time, when the water has been wholly removed by evaporation, and be spread out over the grass lands, particularly those under the scythe, as soon as possible after the hay has been taken off the ground. The benefit of a reservoir of this nature, whether formed in the intention of flowing the land below it, or of a pond for catching the mud, will commonly be in the proportion of its extent. And the cost of it will have a relation likewise to its dimensions. It is supposed, that if the expence of one be ten pounds, and the annual increase of hay only one load, the farmer may well afford to pay six *per cent.* for the use of it. Therefore such reservoirs seldom fail to pay amply for the cost of preparing them. In some sloping situations they may be constructed at a very trifling expence, in comparison of their usefulness, when intended to be thrown over grass lands, with a valve, by which, when full, the liquid may be let off, in a sufficient body, to spread equally over the whole of the part to which it is applied, and produce the full effect that is wanted.

RESERVOIR, in *Anatomy*. See RECEPTACULUM *Chyli*.

RESET, in *Law*, the receiving or harbouring an outlawed person. Hence a receiver of an outlawed person is called a *resetter*.

RESHD, or RESHT, in *Geography*, a town of Persia, and capital of the province of Ghilan, built on the shore of the Caspian, and carrying on a considerable trade in silk, and other articles, with Astrachan. The number of houses, which lie dispersed, is estimated at 2000. The heat in summer is hardly supportable, and dangerous, when a particular wind blows, but happily it does not continue above a quarter of an hour. The harbour is unsafe in stormy weather, so that the commanders of ships generally prefer that of Lankeroon, a small port in the district of Talish, to the N.W. of Resht. Rice and wheat are cultivated in its vicinity; 300 miles N. of Ispahan. N. lat. 37° 20'. E. long. 49° 50'. The province of Ghilan yields a net revenue of 149,490 tomanis, and 9058 dinars.

RESIANCE, RESIANTIA, in *Law*, a man's abode, or continuance in a place.

The word has the same signification with regard to laymen, as *residence* with regard to ecclesiastics.

Glanville observes, that in the ancient law, *resiance* properly signified a disease, by which the person was disabled from stirring out of doors. Whence their *essoin de resiantia*, was the same as our *essoin de malo lecto*.

RESIANT ROLLS, are rolls in which the resiants of a tithing, &c. are set down.

RESIDENCE, RESIDENTIA, in *Canon and Common Law*, the abode of a person, or incumbent, upon his benefice; and his assiduity in attending on the same.

By the rule of the ancient canon law, beneficiaries are obliged to residence, without just and necessary cause, and especially without the consent of the diocesan, under pain of deprivation of their benefices. The original reason is, that in the primitive church none were promoted to holy orders, but such as had a benefice in promptu, which they were obliged to serve; so that this service was necessarily attached to the orders; and whoever was honoured with them, at the same time was obliged to personal service.

Regularly, personal residence is required of ecclesiastical persons upon their cures; and to that end, by the canon law, if he that hath a benefice with cure be chosen to an office of bailiff, or beadle, or the like secular office, he may have the king's writ for his discharge. The intendment of the common law is that a clerk is resident upon his cure. 2 Inst. 625.

Residence is also required by statute 9 Ed. II. stat. 1. c. 8, called the statute *articuli cleri*. Thus also, by 21 Henry VIII. c. 13, commonly called the statute of non-residence, persons wilfully absenting themselves from their benefices for one month together, or two months in the year, incur a penalty of 5*l.* to the king, and 5*l.* to any person that will sue for the same. And if any person or persons shall procure at the court of Rome, or elsewhere, any licence or dispensation to be non-resident at their said dignities, prebends, or benefices, contrary to this act; every such person, putting in execution any such dispensation or licence for himself, shall incur the penalty of 20*l.* for every time so doing, to be forfeited and recovered as aforesaid, and such licence or dispensation shall be void. s. 27.

Provided, that this act of non-residence shall not extend nor be prejudicial to any such spiritual person as shall chance to be in the king's service beyond the sea, nor to any person going to any pilgrimage or holy place beyond the sea, during the time that they shall so be in the king's service, or in the pilgrimage going and returning home; nor to any scholar or scholars being conversant and abiding for study, without fraud or covin, at any university within this realm or without; nor to any of the chaplains of the king or queen, daily or quarterly attending and abiding in the king's or queen's most honourable household; nor to any of the chaplains of the prince or princess, or any of the king's or queen's children, brethren, or sisters, attending daily in their honourable households, during so long as they shall attend in any of their households; nor to any chaplain of any archbishop or bishop, or of any spiritual or temporal lords of the parliament, daily attending, abiding, and remaining in any of their honourable households; nor to any chaplain of any dukes, marquises, countesses, viscountesses, or baronesses, attending daily, and abiding in any of their honourable households; nor to any chaplain of the lord chancellor, or treasurer of England, the king's chamberlain, or steward of his household for the time being, the treasurer and controller of the king's most honourable household for the time being, attending daily in any of their honourable households; nor to any chaplain of any of the knights of the honourable order of the garter, or of the chief justice of the king's bench, warden of the ports, or of the master of the rolls, nor to any chaplain of the king's secretary, dean of the chapel, ammer for the time being, daily attending and dwelling in any of their households, during the time that they shall so abide and dwell, without fraud or covin, in any of the said honourable households; nor to the master of the rolls, or dean of the arches, nor to any chancellor or commissary of any archbishop or bishop, nor to as many of the twelve masters of the chancery, and twelve advocates of the arches, as shall be spiritual men, during so long time as they shall occupy their said rooms and offices; nor to any such spiritual persons as shall happen by injunction of the lord chancellor, or the king's council, to be bound to any daily appearance and attendance to answer to the law, during the time of such injunction. s. 28.

Provided also, that it shall be lawful to the king to give licence to every of his own chaplains, for non-residence upon their benefices; any thing in this act to the contrary notwithstanding. s. 29.

Provided also, that every dukes, marquises, countesses, baronesses, widows, which shall take any husbands under the degree of a baron, may take such number of chaplains as they might have done being widows; and that every such chaplain may have like liberty of non-residence, as they might have had if their said ladies and mistresses had kept themselves widows. s. 33.

Legal residence is not only in the parish, but also in the parsonage

parsonage house; for it hath been resolved, that the statute intended residence, not only for serving the cure, and for hospitality, but also for maintaining the house, that the successor also may keep hospitality there. 25 Hen. VIII. cap. 16. 33 Hen. VIII. cap. 28. 28 Hen. VIII. cap. 13.

On a review of these statutes, a question has occurred, how far, taken together, they supercede the canon law, so as to take away the power which the ordinary had before, of enjoining residence to the clergy of his diocese. It seems to be clear, that before these statutes, the bishops of this realm had and exercised a power of calling their clergy to residence; but more frequently, they did not exert this power, which so far forth was to the clergy a virtual dispensation for non-residence. But this not exerting of their power was in them not always voluntary; for they were under the controlling influence of the pope, who granted dispensations of non-residence to as many as would purchase them, and disposed of abundance of ecclesiastical preferments to foreigners, who never resided here at all. The king also, as appears, had a power to require the service of clergymen; and consequently in such case to dispense with them for non residence upon their benefices. This power of the king is reserved to him by the aforesaid act of the 21 Hen. VIII. c. 13. But it is the power of dispensation in the two former cases which is intended to be taken away, namely, by the bishop, and by the pope; and by the said act residence is enjoined to the clergy, under the penalty therein mentioned, notwithstanding any dispensation to the contrary, from the court of Rome or elsewhere; with a proviso nevertheless, that the said act shall not extend nor be prejudicial to the chaplains and others therein specially excepted. It is argued, that this act being made to rectify what had been insufficient or ineffectual in the canon law, and inflicting a temporal penalty to enforce the obligation of residence, the parliament intended that the said act should be, from thenceforth, if not the sole, yet the principal rule of proceeding in this particular; and consequently, that the persons excepted in the act need no other exemption than what is given to them by the act of their non-residence. Unto this it is answered, that the intention of the act was not to take away any power which the bishop had of injoining residence, but the contrary; namely, it was to take away that power which the bishop or pope exercised, of granting dispensations for non-residence, that is to say, the act left to them that power which was beneficial, and only took from them that which tended to the detriment of the church; and, consequently, that the bishop may injoin residence to the clergy as he might before, only he may not dispense with them as he did before for non-residence. And indeed, from any thing that appears upon the face of the act, the contrary supposition seemeth to bear somewhat hard against the rule which hath generally been adhered to in the construction of acts of parliament, that an act of parliament in the affirmative doth not take away the ecclesiastical jurisdiction, and that the same shall not be taken away in any act of parliament, but by express words. It is therefore further urged, that the three subsequent acts do explain this act, and by the express words thereof do establish the foregoing interpretation. In the first of the three it is said, that the persons therein mentioned may retain one chaplain *which may be absent from his benefice, and not resident upon the same*; in the second it is said, that persons above forty years of age, residing in the universities, *shall not be excused of their non-residence*, and again, that persons under forty years of age, *shall not enjoy the privilege of non-residence contained in the proviso of the said former act*, unless they perform the common exercises there, and the like, which implies, that if they do

this, they shall enjoy such privilege: and in the third, it is said, that the persons therein mentioned may retain one chaplain, *which may be absent from his benefice, and non-resident upon the same*; and it is not to be supposed, that the parliament intended a greater privilege to the chaplains of the inferior officers mentioned in the said last act, than to the chaplains of the royal family and principal nobility mentioned in the first act. Unto this the most apposite answer seemeth to be, that it is not expressed absolutely in any of the said three acts, that the chaplains or others therein mentioned shall enjoy the privilege of non-residence, or may be absent from their benefices, and not resident upon the same; but only this, that they may be absent or non-resident as aforesaid, *the said statute made in the said twenty-first year, or any other statute or ordinance to the contrary notwithstanding*. So that they are only exempted thereby from the restraints introduced by the statute law; but in other respects are left as they were before.—But concerning this, although it is a case likely enough to happen every day, there hath been no adjudication.

By 43 Geo. III. c. 84. it is enacted, that so much of 21 Hen. VIII. c. 13. as imposes the penalty of ten pounds on any spiritual person who shall not keep residence on one of his dignities, prebends, or benefices, but absent himself one month together, or two months, to be accounted at several times, in any one year, shall be, and the same is hereby repealed; and that every spiritual person, being possessed of any archdeaconry, deanery, or other dignity, prebend, benefice, donative, or perpetual curacy, or parochial chapelry, who shall, without sufficient cause, as in the said act, or the 25 Hen. VIII. c. 16. or in 28 Hen. VIII. c. 13. or in 33 Hen. VIII. c. 28. is specified, or such other sufficient cause as would exempt such spiritual person from any of the pains, penalties, and forfeitures under the said recited acts, for any non-residence, and who shall not have any such licence or exemption as is in this act mentioned, wilfully absent himself therefrom for three months together, or to be accounted at several times in any one year, and make his residence at any other place or places, except at some other dignity, prebend, benefice, donative, perpetual curacy, or parochial chapelry, of which he may be possessed, shall, when such absence shall exceed such period, and not exceed six months, forfeit and pay one-third of the annual value of the dignity, prebend, benefice, donative, perpetual curacy, or parochial chapelry, from which he shall so absent himself; and when such absence shall exceed six months, and not eight months, one-half of such annual value; and when such absence shall exceed eight months, two-thirds of such annual value; and when such absence shall have been for the whole of the year, three-fourths of such annual value; to be recovered by action of debt, bill, plaint, or information, in any of his majesty's courts of record at Westminster, or the courts of great sessions in Wales, wherein no essoign, privilege, protection, or wager of law, or more than one imparlance, shall be allowed; and the whole of every such penalty or forfeiture shall go and be paid to the person or persons who shall inform and sue for the same, together with such costs of suit as shall be allowed; provided that no parsonage that hath a vicar endowed, or perpetual curate, and having no cure of souls, shall be taken to be or be comprehended under the name of benefice, within the meaning of this act. s. 12.

No spiritual person holding any office, in such manner as the same, under any of the provisions of the said recited acts, would exempt such spiritual persons from residence, or from the penalties and forfeitures in the said acts contained for non-residence, or actually serving as a chaplain of the house of commons, or as a clerk of his majesty's closet, or as

a deputy clerk thereof, or as a chaplain general of his majesty's forces, or brigade chaplain on foreign service, or chaplain on board any of his majesty's ships, or of his majesty's dock yards, or in any of his majesty's garrisons, or chaplain of his majesty's corps of artillery, or as chaplain to any British factory, or in the household of any British ambassador or public minister residing abroad, or as chancellor or vicar-general, or in his absence the principal surrogate or official in any ecclesiastical court of any diocese, or as minor canon, or vicar choral, or priest, vicar, or any such other public officer in any cathedral or collegiate church, or as deans, sub-deans, priests, or readers in his majesty's royal chapels at St. James's and Whitehall, or as reader in his majesty's private chapel at Windsor, or elsewhere, or as chaplain at the royal military asylum at Chelsea, or royal military college at High Wycombe, or teacher at the royal military academy at Woolwich, or chaplains at the royal hospitals at Greenwich and Chelsea, or as chaplains to the royal hospitals for seamen at Haslar and Plymouth, or as a preacher or reader in any of the inns of court, or at the rolls, or as burfard, dean, vice-president or public tutor or chaplain, or other such public officer, in any college or hall, in either of the universities of Oxford or Cambridge, or as public librarian or public registrar, or proctor, or public orator, or other such public officer, in either of the said universities, or as fellow of any college in either of the universities, or of Eton or Winchester college, or as warden or provost of Eton or Winchester college, or as schoolmaster or usher in the same, or as schoolmaster or usher of Westminster-school, during the period that they shall respectively be required, by reason of any such office, to perform the duties of the same, and actually shall perform the duties of the same, shall be liable to any of the pains, penalties, or forfeitures in the said first recited act or this act contained, for or on account of any non-residence on any dignity, prebend, benefice, donative, or perpetual curacy. f. 15.

It shall be lawful for any bishop to grant licences to spiritual persons within his diocese, to reside out of the proper house of residence, or out of the parish, and within such distance therefrom, as the case may appear to such bishop to require, if such bishop shall, in his discretion, think the same fit and proper, in the several cases hereinafter mentioned; (that is to say,) to any spiritual person who shall be prevented from residing in the proper house of residence, or in the parish, by actual illness of himself, or wife or child; and also to any spiritual person having any dignity, prebend, benefice, donative, perpetual curacy, or parochial chapelry, where there shall be no house of residence, or where the house of residence shall be unfit for the residence of such ecclesiastical person, such unfitness not being occasioned by such ecclesiastical person, such spiritual person keeping such house in such repair as shall be to the satisfaction of the bishop; and also to any spiritual person having any benefice, donative, perpetual curacy, or parochial chapelry, and having any mansion or messuage belonging to himself or any relative, to reside in such mansion or messuage, such spiritual person keeping the house of residence in good repair, to the satisfaction of the bishop; and also to any spiritual person having any benefice, donative, perpetual curacy, or parochial chapelry, of small value, and serving as a stipendiary curate elsewhere, with licence, and providing for the serving of such his benefice, donative, perpetual curacy, or parochial chapelry, to the satisfaction of the bishop of his diocese; and also to any master or usher of any endowed school duly licensed by the bishop, and actually employed in teaching therein, or to the master of any other

school who now is or shall be, within one month after the passing of this act, duly licensed by the bishop; and also to any master or preacher of hospitals or incorporated charitable foundation, during the period for which he may be required to reside in the same, and shall actually reside and perform his duties therein; or to any person holding any endowed lectureship, chapelry, or preacher'ship, and performing the duties thereof respectively; or to any spiritual person having any benefice, donative, perpetual curacy, or parochial chapelry of small value, and serving as preacher in any proprietary chapel in cities or towns, with the licence of the bishop in whose diocese he shall so officiate; or to the librarians of the British museum, or of Sion college; or to the trustees of lord Crewe's charity, during the times of their personal attendance on the duties of their office: provided always, that for any such licence, the party obtaining the same shall not pay more than the sum of ten shillings, exclusive of any such stamps as may be required by law: provided always, that if any spiritual person, applying to any bishop for any such licence, shall think himself aggrieved by the refusal thereof, it shall be lawful for such spiritual person to appeal to the archbishop of the province, who shall confirm such refusal, or grant a licence under this act, as shall seem just and proper. f. 19.

It shall be lawful for any bishop, in cases not enumerated, to grant licences to reside out of the proper house of residence, or out of the parish, and to assign to a curate such salary as he shall judge fit: provided, that in every such case, the reasons that have induced such bishop to grant such licence shall be transmitted to the archbishop of the province to which such bishop shall belong, who shall allow or disallow such licence, in the whole, or in part, or make any alteration therein, as to the period for which the same may have been granted, or otherwise, and likewise as to the stipend assigned to the curate, as to such archbishop shall seem fit; and no such licence shall be good unless it shall have been so allowed and approved by such archbishop: provided also, that no licence shall be made void by the death or removal of the bishop or archbishop granting the same, but the same shall be good and valid, unless the same shall be revoked by the next or any succeeding bishop or archbishop: provided also, that any spiritual person may appeal against any such revocation by the bishop alone: provided also, that the respective archbishops may, in their respective dioceses of which they are bishops, grant licences in all cases in which any licences may be granted by any bishop, either by his own authority, or with the allowance and approval of the archbishop as aforesaid: provided also, that it shall be lawful for any such archbishop to order reasonable fees and charges to be paid by any such spiritual person appealing: provided always, that in every case when any costs and charges directed by such archbishop or bishop as aforesaid, shall remain unpaid for the period of twenty-one days after demand thereof, it shall be lawful for such bishop or archbishop to cause the same to be recovered by sequestration. f. 21.

Provided always, that it shall be lawful for any bishop or archbishop to revoke any such licence: provided also, that no licence for non-residence granted under this act shall continue in force for more than two years from the granting thereof.

Every bishop or archbishop shall cause a copy of such licence or revocation to be filed in the registry of the diocese; and a list shall be made out by the registrar of the said diocese, and entered in a book, and kept for the inspection of all persons; and a copy of every such licence and revocation shall be transmitted to the churchwardens of the parish to which the same relates, within one month after the grant thereof,

## RESIDENCE.

thereof, to be by them deposited in the parish chest; and a copy of the same shall likewise be read at the visitation of the archdeacon. f. 22.

Provided, that during the vacancy of any see, the power of granting licences under this act shall be exercised by the vicar-general of the diocese; and that during the absence of any prelate out of the realm, or such infirmity as disables him from exercising in person the functions of his office, it shall be exercised by such person or persons as is or are lawfully empowered to exercise his general jurisdiction in the diocese. f. 28.

And nothing in this act shall exempt any person or persons from any canonical or ecclesiastical censures, or affect any proceedings in any ecclesiastical court, in relation to non-residence, not being duly licensed according to the provisions of this act, to be absent therefrom, nor having any other lawful cause of absence; provided no such censures, by reason of any non-residence, not exceeding three months in any one year, shall be put in force at the suit or instance of any person or persons other than the archbishop, bishop, or archdeacon. f. 29.

In every case in which it shall appear to any bishop or archbishop, that any spiritual person, not being licensed according to this act, nor having any other lawful cause of absence, does not sufficiently reside, it shall be lawful for such bishop or archbishop to issue a monition to such spiritual person, to reside thereon, and to make a return to such monition within a certain number of days after the issuing thereof; so as that there shall be thirty days between the time of executing such monition, and the time specified for the return thereto; and it shall be lawful for the bishop or archbishop to whom any such return shall be made, to require such return to be verified by the oath of such spiritual person, or others; and where no such return shall be made, or where such return shall not be deemed satisfactory, it shall be lawful for such bishop or archbishop to issue an order to require such person to proceed to and reside, within thirty days after such order shall have been delivered; and in case of non-compliance, to sequester the profits of such benefice, donative, perpetual curacy, or parochial chapelry of such spiritual person, and to direct the application of such profits, after deducting the necessary expences of serving the cure, to the payment of such expences as shall have been incurred in relation to such monition and sequestration, and in the next place, towards the augmentation or improvement of any such parsonage, vicarage, donative, or perpetual curacy, or the house of residence, or any of the buildings and appurtenances, or any of the glebe or demesne lands; or may order and direct the same, or any portion thereof, to be paid to the governors of the bounty of queen Anne, to be applied as such bishop or archbishop shall in his discretion think fit; and it shall also be lawful for any such bishop or archbishop, within six months after such order for sequestration, or within six months after any money shall have been actually levied by such sequestration, to remit to any such spiritual person any part of such profits, or cause the same or any part thereof that shall have been paid to such governors of queen Anne's bounty, to be repaid to such spiritual person, in any case in which, by reason of the subsequent obedience of any such spiritual person, such bishop or archbishop shall think the same proper: provided, that when any such spiritual person shall think himself aggrieved by reason of any such sequestration, it shall be lawful for any such spiritual person to appeal to the archbishop, who shall make such order as shall be just and proper: provided, that the party so appealing shall give security to the bishop for the payment of ex-

pences occasioned by the appeal: provided also, that no such order for any sequestration shall be put in force during such appeal. f. 30.

Persons who shall return to residence on monition, shall pay the colls. f. 31.

If any person, returning to residence on monition, shall before six months thereafter absent himself, the bishop may, without monition, sequester the profits of the benefice. f. 32.

And if any clerk shall continue under any sequestration for non-residence for the space of three years, or shall incur three sequestrations in the said space of three years, not being relieved with respect to any of such sequestrations, upon appeal, the benefice shall become *ipso facto* void, and the patron or person entitled to present or nominate some clerk thereto, other than the clerk who shall have so continued under such sequestration or sequestrations. f. 33.

Provided, that if an action be brought before the issuing of the monition, the bishop or archbishop shall retain out of the profits of the benefice sufficient to satisfy the penalty and costs; but if at the time of filing the monition, no action shall have been commenced, none shall be brought afterwards. f. 36.

But nothing in this act contained shall affect his majesty's royal prerogative in the granting of dispensations for non-residence, nor any privilege of clerks retained in his majesty's service under the statute 9 Edward II. c. 8.— f. 40.

No archbishop or bishop having any dignity, prebend, benefice, donative, or perpetual cure, shall, by reason of non-residence, be subject or liable to any penalties or forfeitures. f. 41.

By 54 Geo. III. c. 175. bishops are empowered to punish past non-residence by monition and sequestration, as well as to compel residence in future, and to exercise the same powers of remitting or ordering the repayment of any part of such penalties as is directed or allowed in 43 Geo. III. c. 84. Persons may appeal, as under the last cited act, and penalties may be remitted; nor are penalties recoverable for more than one year. This statute repeals the provision of the former act 43 Geo. III. as to persons neglecting to notify the cause of exemption from residence, for which it is not necessary to obtain a licence, and enacts that a person chargeable with such neglect shall forfeit and pay for such offence the sum of 20*l.* to be levied by sequestration, if not otherwise paid after monition, to be applied as the archbishop or bishop of the diocese to whom the notification ought to have been made shall direct, who possesses the power of remitting or ordering the repayment of any part of such penalties, as is allowed in the said act, in cases of non-compliance with an order for residence. A person who has no house of residence, but who shall have resided nine months in the year within the limits of his benefice, donative, perpetual curacy, or parochial chapelry, shall not be liable to any penalties on account of non-residence, nor be obliged to take out any licence for it; but the same shall be deemed a legal residence; and in all returns made by the bishops, persons so residing shall be returned as resident. It is enacted also, that houses purchased by the governors of queen Anne's bounty, though not situated within the parishes for which they are purchased, shall be deemed residences; and in all cases of sinecure rectories having vicarages endowed, the residence of the vicar in the rectory house shall be deemed a sufficient legal residence.

For leases of non-residents, see LEASE.

We observe here, that the act of 13 Eliz. c. 20, referred to under LEASE, which was at first temporary, but made perpetual by 3 Car I. c. 4, is repealed by 43 Geo. III. c. 84, as well as several other statutes, so far as they relate to it. This statute enacts, that spiritual persons may take houses, &c. though not in a city, &c. and such as have not sufficient glebe may, by consent of the bishop, take farms. They may also hold estates as property, but not any farm for cultivation, unless under a lease granted on or before Jan. 1, 1803, or by consent of the bishop. They may also buy or sell cattle or corn for the occupation of farms. Vicars or curates may take leases of the impropriate parsonages of their parishes; but if not occupied by a spiritual person before the passing of this act, the licence of the bishop is necessary. A licensed clergyman, or one exempt from residence, may occupy, where he resides, such lands as the bishop may allow. This statute is amended, in several respects, by 54 Geo. III. c. 175. By one clause in this last act, so much of 53 Geo. III. c. 149, as enacts that incumbents, neglecting to notify the death of a curate, shall lose his exemption from residence, or licence for non-residence, is repealed; and a penalty of 20*l.* is imposed.

By 53 Geo. III. c. 149. s. 2, the bishop or ordinary is empowered to appoint salaries to licensed curates; the licence specifying the amount of such salary; and curates may be directed to reside in the parsonage house in case of the non-residence of incumbents for four months in each year, during the said non-residence: but the distance of the residence of such curate, licensed to reside out of the parish, from any church or chapel which he shall be licensed to serve, shall not exceed five statute miles, except in cases of necessity, to be approved by the bishop or ordinary, and specified in the licence. The bishop may direct the curate to give up possession of the parsonage or vicarage house, and in case of refusal, he shall forfeit to the rector or vicar, all such parts of his stipend as shall then be unpaid, or shall thereafter become due, and also the sum of 50*l.* to such rector or vicar, recoverable in an action of debt. The salaries payable to curates shall be in proportion to the value of the benefices; in no case less than 80*l. per annum*, or than the annual value of the benefice, donative, perpetual curacy, or parochial chapelry, if the said value shall not amount to 80*l. per annum*; nor less than 100*l. per annum*, or the whole value as aforesaid, if the said value shall not amount to 100*l. per annum* in any parish or place where the population, (according to the returns then last made in pursuance of any act or acts of parliament,) shall amount to or exceed 300 persons; and such salary shall not be less than 120*l. per annum*, or the whole value as aforesaid, if the said value shall not amount to 120*l. per annum*, in any parish or place where the population shall appear as aforesaid to amount to or exceed 500 persons; and such salary shall not be less than 150*l. per annum*, or than the whole value as aforesaid, if the said value shall not amount to 150*l. per annum*, in any parish or place where the population shall appear, as aforesaid, to amount to or exceed 1000 persons: provided always, that the annual value of all benefices, donatives, perpetual curacies, or parochial chapelries, of which the said value, estimated as is herein provided, does not amount to 150*l. per annum*, shall be estimated from the returns made by the bishops of the several dioceses to the governors of queen Anne's bounty, in pursuance of an address of the house of lords, or from any future returns which may be made by the said bishops to the said governors, respecting parishes or places omitted in the said returns, or respecting parishes or places in the actual income of which it shall be

made appear to the said bishops that any considerable variation has taken place, either by augmentations made by the said governors or otherwise.

However, where the curate's salary is of the value of the benefice, it shall be liable to the charges affecting it. When the curate is permitted to serve in an adjoining parish, it shall be lawful for the bishop or ordinary to appoint for such incumbent, or perpetual curate, so licensed, a salary less by a sum not exceeding 30*l. per annum*, than the salary which in the several cases herein before mentioned the bishop or ordinary is respectively required by this act to appoint; and in every case where the bishop or ordinary shall find it necessary or expedient as aforesaid, to license one and the same person to serve as curate for two adjoining or other parishes or places, it shall be lawful for such bishop or ordinary to direct that during such time as such curate shall serve such two churches or chapels, the salary to be received by him for serving each of the said churches or chapels shall be less by a sum not exceeding 30*l. per annum*, than the salary which in the several cases herein before mentioned the bishop or ordinary is required by this act to appoint: Provided always, that no such salary shall in any case be less than 50*l. per annum*, or than the whole value of the said benefice, donative, perpetual curacy, or parochial chapelry, which such incumbent, perpetual curate, or curate, shall be licensed to serve, if the said value shall not amount to 50*l. per annum*: Provided always, that no incumbent, perpetual curate, or curate, shall be licensed to serve as curate in any church or chapel which is distant more than five statute miles from any church or chapel already served by such incumbent, perpetual curate, or curate, except in cases of necessity, to be approved by the bishop or ordinary, and specified in the licence.

In certain cases, smaller salaries are to be allowed to curates. The bishop is to allow the rector, &c. to deduct from the curate's salary for repairs to a limited amount, so that it shall not in any year exceed one-fourth part of the salary allotted to the curate. The curate is required, in certain cases, to pay the taxes of the parsonage house. Where the benefice, clear of all deductions, exceeds 400*l. per annum*, the bishop may assign to the curate of such parish or place, resident within the same, and serving no other cure, a salary of 100*l. per annum*, though the population may not amount to 300 persons; and if the population should amount to 500 persons, the bishop may assign to the curate any larger stipend or allowance, so that the same shall not exceed by more than 50*l. per annum* the amount of the stipend or allowance before specified, as required to be assigned to such curate. No licence shall be granted to serve more than two churches in one day; excepting only in certain cases, where three chapels or churches are not distant from each other more than four measured miles, the reasons for granting such licence being stated in it; and it is required that the residence of the curate be such, that it shall not be necessary for him to travel more than fifteen miles to perform his whole duty. An incumbent applying for licence for non-residence shall state what salary he proposes to give to his curate. See CURATE.

Bishops are not punishable by the statute of the 21 Hen. VIII. for non-residence upon their bishoprics; but although an archbishop or bishop be not tied to be resident upon his bishopric by the statutes; yet they are thereto obliged by the ecclesiastical law, and may be compelled to keep residence by ecclesiastical censures. (Watf. c. 37.) See also the constitutions of archbishop Langton, of Otho, and of Othobon. By canon 42, every dean, master, or warden, or chief governor of any cathedral or collegiate church, shall be resident in the same fourcore and ten days, *conjunctim* or *divisim*,

## RESIDENCE.

*Abſent*, in every year at the leaſt, and then ſhall continue there in preaching the word of God, and keeping good hoſpitality; except he ſhall be otherwiſe let with weighty and urgent cauſes, to be approved by the biſhop of the dioceſe, or in any other lawful fort diſpenſed with.

By can. 44 no prebendaries nor canons in cathedral or collegiate churches, having one or more benefices with cure, (and not being reſidentiaries in the ſame cathedral or collegiate churches,) ſhall, under colour of their ſaid prebends, abſent themſelves from their benefices with cure above the ſpace of one month in the year, unleſs it be for ſome urgent cauſe, and certain time to be allowed by the biſhop of the dioceſe. And ſuch of the ſaid canons and prebendaries, as by the ordinances of the cathedral or collegiate churches do ſtand bound to be reſident in the ſame, ſhall ſo among themſelves ſort and proportion the times of the year, concerning reſidence to be kept in the ſaid churches, as that ſome of them always ſhall be perſonally reſident there; and all thoſe who be, or ſhall be reſidentiaries in any cathedral or collegiate church, ſhall, after the days of their reſidency appointed by their local ſtatutes or cuſtom expired, preſently repair to their benefices, or ſome one of them, or to ſome other charge where the law requireth their preſence, there to diſcharge their duties according to the laws in that caſe provided. And the biſhop of the dioceſe ſhall ſee the ſame to be duly performed and put in execution.

So that, beſides the general laws directing the reſidence of other clergymen, theſe dignitaries have another law peculiar to themſelves, namely, the local ſtatutes of their reſpective foundations, the validity of which local ſtatutes this canon ſuppoſeth and affirmeth. And, with reſpect to the new foundations in particular, the act of parliament of the 6 Anne, c. 21. enacteth that their local ſtatutes ſhall be in force, ſo far as they are not contrary to the conſtitution of the church of England, or the laws of the land. This canon is undoubtedly a part of the conſtitution of the church: ſo that if the canon interfere in any reſpect with the ſaid local ſtatutes, the canon is to be preferred, and the local ſtatutes to be in force only ſo far forth as they are modified and regulated by the canon.

There doth not appear to be any difference, either by the eccleſiaſtical or temporal laws of this kingdom, between the caſe of a rector and of a vicar concerning reſidence; except only that the vicar is ſworn to reſide, (with a proviso, unleſs he ſhall be otherwiſe diſpenſed withal by his dioceſan,) and the rector is not ſworn. And the reaſon of this difference was this: in the council of Lateran, held under Alexander III., and in another Lateran council, held under Innocent III., there were very ſtrict canons made againſt pluralities; by the firſt of theſe councils pluralities are reſtrained, and every perſon admitted *ad eccleſiam, vel eccleſiaſticum miniſterium*, is bound to reſide there, and perſonally ſerve the cure; by the ſecond of theſe councils, if any perſon, having one benefice with cure of ſouls, accepts of a ſecond, his firſt is declared void *ipſo jure*. Theſe canons were received in England, and are ſtill part of our eccleſiaſtical law.

At the firſt appearance of theſe canons, there was no doubt made but they obliged all *rectors*; for they, according to the language of the law, had churches *in title*, and had *beneficium eccleſiaſticum*: and of ſuch the canons ſpoke. But *vicars* did not then look upon themſelves to be bound by theſe canons, for they, as the gloſs upon the decretals ſpeaks, had not *eccleſiam quoad titulum*; and the text of the law deſcribes them, not as *having benefices*, but as bound *perſonis et eccleſiis deſervire*, that is, as aſſiſtant to the rector in his church.

Upon this notion a practice was founded, and prevailed in England, which eluded the canons made againſt pluralities. A man beneficed in one church could not accept another, without avoiding the firſt; but a man poſſeſſed of a benefice, could accept a vicarage under the rector in another church, for that was no benefice in law, and therefore not within the letter of the canon, which forbids any man holding two benefices.

The way then of taking a ſecond living in fraud of the canon was this: a friend was preſented, who took the inſtitution, and had the church *quoad titulum*; as ſoon as he was poſſeſſed, he conſtituted the perſon vicar for whoſe benefit he took the living, and by conſent of the dioceſan, allotted the whole profit of the living for the vicar's portion, except a ſmall matter reſerved to himſelf.

This vicar went and reſided upon his firſt living, for the canon reached him where he had the *benefice*; but having no benefice where he had only a vicarage, he thought himſelf ſecure againſt the ſaid canons requiring reſidence.

This piece of management gave occaſion to ſeveral papal decrees, and to the following conſtitution of archbiſhop Langton; *viz.* No ordinary ſhall admit any one to a vicarage, who will not perſonally officiate there. Lind. 64.

And to another conſtitution of the ſame archbiſhop, by which it is enjoined, that vicars who will be non-reſident ſhall be deprived. Lind. 131.

But the abuſe ſtill continued, and therefore Otho, in his legatine conſtitutions, applied a ſtronger remedy, ordaining, That none ſhall be admitted to a vicarage, but who, renouncing all other benefices (if he hath any) with cure of ſouls, ſhall ſwear that he will make reſidence there, and ſhall conſtantly ſo reſide: otherwiſe his inſtitution ſhall be null, and the vicarage ſhall be given to another. Athon. 24.

And it is upon the authority of this conſtitution that the oath of reſidence is adminiſtered to vicars to this day. And this obligation of vicars to reſidence was further enforced by a conſtitution of Othobon, as followeth: If any ſhall detain a vicarage contrary to the aforeſaid conſtitution of Otho, he ſhall not appropriate to himſelf the profits thereof, but ſhall reſtore the ſame; one moiety whereof ſhall be applied to the uſe of that church, and the other moiety ſhall be diſtributed half to the poor of the pariſh, and half to the archdeacon. And the archdeacon ſhall make diligent inquiry every year, and cauſe this conſtitution to be ſtrictly obſerved. And if he ſhall find that any one detaineth a vicarage contrary to the premiſes, he ſhall forthwith notify to the ordinary that ſuch vicarage is vacant, who ſhall do what to him belongeth in the premiſes; and if the ordinary ſhall delay to inſtitute another into ſuch vicarage, he ſhall be ſuſpended from collation, inſtitution, or preſentation to any benefices until he ſhall comply. And if any one ſhall ſtrive to detain a vicarage contrary to the premiſes, and perſiſt in his obſtinacy for a month; he ſhall, beſides the penalties aforeſaid, be *ipſo facto* deprived of his other benefices (if he have any); and ſhall be diſabled for ever to hold ſuch vicarage, which he hath ſo vexatiously detained, and from obtaining any other benefice for three years. And if the archdeacon ſhall be remiſs in the premiſes, he ſhall be deprived of the ſhare of the aforeſaid penalty aſſigned to him, and be ſuſpended from the entrance of the church, until he ſhall perform his duty. Athon. 95.

So that, upon the whole, the doubt was not, whether rectors were obliged to reſidence; the only queſtion was, whether vicars were alſo obliged: and to enforce the reſidence

dence of vicars, in like manner as of rectors, the aforesaid constitutions were ordained. Sherl. *ibid.* p. 20, 21, 22.

By the 43 Geo. III. c. 84. no oath shall be required of or taken by any vicar in relation to residence on his vicarage. f. 37.

Can. 47. Every beneficed man licensed by the laws of this realm, upon urgent occasions of other service, not to reside upon his benefice, shall cause his cure to be supplied by a curate that is a sufficient and licensed preacher, if the worth of the benefice will bear it. But whosoever hath two benefices, shall maintain a preacher licensed in the benefice where he doth not reside, except he preach himself at both of them usually.

And by the last article of archbishop Wake's directions it is required, that the bishop shall take care, as much as possible, that whosoever is admitted to serve any cure, do reside in the parish where he is to serve; especially in livings that are able to support a resident cure: and where that cannot be done, that they do at least reside so near to the place, that they may conveniently perform all their duties, both in the church and parish.

By the 36 Geo. III. c. 83. the ordinary, besides appointing to curates an allowance not exceeding 75*l.* per ann. may, on livings where the rector or vicar does not personally reside four months in the year at least, grant the use of the rectory or vicarage house, and the garden and stable thereto belonging, such use to be granted to the said curate for the space of twelve calendar months by the authority of the ordinary, under his hand and seal, with power in the said ordinary to renew and grant from time to time, or a further sum, not exceeding 15*l.* per ann. in lieu of such house, garden, and stable, in case there shall be none such, or it shall appear to him not to be convenient to allot and assign the same to such curate. Provided that the said house, garden, and stable, shall be for the use of the said curate and his family only during his *actual* residence in the said rectory and vicarage house. Provided also, that the ordinary shall have power at any time under his hand and seal, to revoke the grant to the said curate of the said house, garden, and stable, or any of them, and also to insert in such grant such terms and conditions to be observed on the part of the curate as he shall think reasonable.

By the faculty of dispensation, a pluralist is required, in that benefice from which he shall happen to be most absent, to preach thirteen sermons every year; and to exercise hospitality for two months yearly, and for that time, according to the fruits and profits thereof, as much as in him lieth, to support and relieve the inhabitants of that parish, especially the poor and needy.

By the 1 W. c. 26. if any person presented or nominated by either of the universities to a popish benefice with cure, shall be absent from the same above the space of sixty days in any one year; in such case, the said benefice shall become void. Burn's *Eccles. Law*, art. *Residence*.

RESIDENCE, in *Chemistry*, &c. the *settling*, or what remains of a liquor, or other substance, in the vessel after the chief part of it has been poured or taken out, to change the manner of the operation on what is left.

RESIDENCE, *Country*, in *Ornamental Gardening*, a rural habitation, mansion, or other kind of place, where it, as well as the ground which surrounds it, are formed and laid out in some sort of ornamental style. There have been a great many ways of accomplishing this proposed at different times, which have given rise to the variety of styles that have prevailed at different periods; but the *avowedly formal*, and the *affectedly graceful*, are the two which have been chiefly had recourse to, according to the writer of the

"Treatise on Country Residences," before that of the *free*, characteristic, natural one, which he has suggested the introduction of; which is confined to no particular style or mode, but which furnishes and supplies beauties and effects which are suitable to the scene and situation, whatever the age or country may be from which they are borrowed, or by whatever epithets they may be called or known.

Suppose a piece of ground containing from four to five hundred acres, of which more than three hundred are to be formed into a residence; that a brook may pass through it, partly among meadows or wastes of copse and pasture, and partly along the hedge fences; that two farm-houses, some cottages, and belts of planting may likewise appear; that the farm-house in the centre is on the highest ground, which descends in varied and gentle slopes on every side to the margin of the brook, except toward a cluster of cottages upon the banks of it, where it abruptly terminates in a wooded precipice of rocks or gravel, or something of a similar kind.

The manner of forming a residence, in such a situation, according to the ancient formal style of a century ago, would, in the first place, have been to clear away every cottage, hedge, and tree; then to level down the precipice, and all irregularities. After which to form it into square fields and avenues, planting belts of trees between them. Two small woods would have been placed on each side of the house, and a large one near the garden. The water of the brook would have been introduced through a conduit, to an oblong canal; from that to two round basins in the central garden; thence to another oblong canal answering to the first. From that, under ground, as before, to two ponds in the large wood; after which to be carried by the side of the outer strip of plantation until it rejoined the former canal. The other parts are not very material. But it may be noticed that the surrounding fields would have nothing done to them, but the removal of the cottages, and the belt of planting, which would otherwise have closed the view from the avenue. The short avenues would probably be continued through the fields in single rows of trees.

And according to the affectedly graceful, or more modern style of Brown and his followers, the same portion of land would have been laid out by means of clearing, levelling, and smoothing the irregularities of the surface in the first instance, only leaving a single small cottage properly hidden by the belt of planting. The house would be built on the highest part of the ground. The whole of the offices sunk under or below it, with the exception of the stables; and the part of the house which is seen, in the form of a cube, with a large front, visible only on the side on which is the approach. The brook elevated upon the side of the rising ground, and formed into a still river, with cascades and islands, which are capable of being seen all round from the house. The park surrounded with a belt, inclosing a ride or drive within this, the whole diversified with clumps of various sizes, but mostly similar in shape. The park fed with deer, sheep, and cattle, and the more considerable spaces in the drive, with the whole of the pleasure ground, regularly mown. Buildings would be introduced in various places in the drives as well as the park. The approach and walks formed in different turns and windings, and the pleasure ground, and kitchen garden, in a regular manner, the latter mostly in the perfectly square form. From each of the drives, the approach, walks, and the pleasure ground, the objects of view are either the ornamental buildings or the mansion, vistas being made in all places from the one to the other; the belt excludes the whole of the distant country from the lower parts of the ground, and the clumps from

## RESIDENCE.

the higher, as well as from the house. It may be supposed that nothing would be done to the surrounding country, only, perhaps, that in the place of the removed cottages, a formal street, under the title of improved village, might be formed and raised at a suitable distance from the mansion and its approach. It is suggested that numbers of places in this country, as well as in Scotland, are laid out nearly in this manner; and that the general pastures, the *belt*, the *clump*, the *tame* and *still* river, abound in both countries, and continue to be formed in the same way, whatever may be the natural character of the situation or place.

But according to the characteristic or natural manner which the writer has advised, such a situation should be laid out somewhat in this way. The house should be placed on the abrupt termination of the rising grounds, the whole of the offices be brought more or less into view, each of such buildings being made low, irregular, and suitable to the nature of the ground. The brook be rendered more characteristic as such, by having little aits and islands formed in it, as well as occasional pools, or stagnated spots of water, in the open parts, and under the shade of the grove where not seen. Near the house, in the hollow, it should spread out in the manner of a lake, being varied by prominences, islands, and wood. The stable offices, kitchen garden, and farm, should be placed near each other, and at no great distance from the main residence. The wood should be seen in one extensive irregular mass, crowning the large eminence, and connecting it with the lower grounds in which the brook runs. Instead of surrounding the whole with a belt of planting, the borders of the park should every where blend in an irregular manner with the country; in some places a hedge only, in others a funk fence, and in a few open places should separate it from the corn-fields; in different places large portions of it may be united to the country by means of hurdle fences, in which way more or less of it may be inclosed and let out to tenantry as thought proper. In this mode, the wood does not terminate abruptly with the park; but gradually loses itself in scattered trees, hedge-rows, and occasional strips among the corn lands of the neighbouring farms. Hence, it is suggested, arise the beauty of the views in walking round the outside border of the park. An irregular village should be formed by scattered cottages, wood, and pasture, from which the approach is led to the house; with a branch to the offices and the garden; the farm road is mostly concealed, but might often be partially seen with advantage. Walks should be formed in different parts of the grounds; those for morning and evening should be extensive and open; those for noon wholly under the wood. They both afford considerable variety, whether the beauty and wildness of the park, the views of the distant corn-fields and hedge-rows, the village, the brook, or the different picturesque compositions formed by the house and offices be regarded; without saying any thing concerning distant prospect, which, in the other practice, is often lost by the belt, and at all events constantly prevented from harmonizing with the park, by its dark distant boundary. The cattle may be guarded and kept off from the front of the mansion by some proper sort of fence, and a certain space along the border and rivulet be preserved as pleasure ground, in which exotic shrubs and flowers may be planted in dispersed natural-like groups and thickets. The whole of the other parts of the ground may be fed with cattle, horses, deer, and sheep, as well as other animals. The kitchen garden, in such a situation, need not be so large as in other cases, as many culinary vegetables may be grown in other places, and the fields of the farm. Nor will an orchard be necessary in many cases, as a sufficient number of

fruit-trees may be introduced in the groups, and pleasure-ground scenery. There may, besides these, be some other differences made, which need not be noticed in this place. A drive may be made through the park as thought proper, and through the surrounding country according to the circumstances of it as connected with the park. The planting in the park should abound with low growths and wildnesses, in the nature of the trees and the various masses of wood in it.

The same spot of ground is displayed as formed and laid out after these three different methods, in the work already alluded to, which may be consulted with much advantage by the inquirer on this head.

In comparing the leading distinctions between the two latter of the above methods of forming and laying out rural residences, or that followed by Brown, Repton, and others, and that which has been suggested by the writer; it is remarked that, in relation to the *whole*, the object of the *former* is to render a residence separate from the country; while the *latter*, or the characteristic style of forming, and the improvements proposed in residences already formed on bad principles, tend to harmonize it. In relation to the parts, that sort of gardening forms and places every thing distinctly and alone; while this groups and connects them with each other, and with the whole.

In what regards *wood*, the vulgar practice is, it is said, to shut out the country by a belt, and to vary the space within by the clumps: while that which is proposed tends to increase the expression and character of the situation or place, whatever part of the grounds it may direct to be wooded, whether in the middle or the boundaries; and instead of shutting out the country, the wood diverges in a gradual manner into hedge-rows, so as to unite and harmonize it as much as possible with the residence.

In respect to *buildings*, the former or common way is to conceal every thing except the mansion: while this, on the contrary, shews every building, not as single objects, but as compound parts of the scenery of the place.

In relation to *water*, the old or former plan is to produce quantity or extent of surface, and to render it as conspicuous as possible: while the style here proposed is to produce natural character.

In respect to *ground*, the former or modern system is to smooth and form undulating surfaces: while that of this is to attend to natural character.

In what regards *parks*, modern landscape gardening, it is said, makes them smooth and destitute of under-growths, ferns, and other plants: while this, by introducing hollies, thorns, briars, ferns, and sometimes furze, broom, and brambles, gives them a wild forest character, which is the great and main object of their formation and arrangement.

In respect to *pleasure-ground*, the common mode, it is said, is to form many acres of lawn, which are to be kept in preservation at a great expence, while they produce nothing. The plan here proposed admits of more or less, according to circumstances and situation, but generally forms little that is not grazed by sheep or covered by flowers, extensive mowing being therefore never requisite, and it commonly permits the cattle to come within a small distance of the residence.

The difference of expence will, it is supposed, be very considerable, as must be evident from the general consideration of the difference between assisting what Nature has already begun, and counteracting her altogether. This will be so whether it relates to the mansions, buildings, planting, water, gardens, farms, or pleasure-grounds. And there will be differences

differences of a minor nature on all these heads, as well as on many others.

The ideas respecting the latter of these methods of forming and laying out residences of this nature, have yet been but little put in practice, nor their union in the mind of any one person been such as to produce a distinct style in regard to them, except, perhaps, with the writer of the work before alluded to. They are, however, of considerable importance, and highly deserving of attention, not only as being founded on the principles of nature, but as according so well with the nature of rural scenery.

In chusing situations for residences of this description, it is advised, that attention should be particularly paid to such as are most convenient in what respects site and position, as they relate to the adjoining country; that they should be the most striking which the grounds will afford; and that they should furnish the best views from the residences of the surrounding country which it is capable of supplying.

A perfect knowledge of what is deficient, and whether that which is wanted can be supplied by the proposed site, or is wholly wanting, or some others deficient that cannot readily be afforded, will greatly contribute to the decision of the first point. And much assistance, in some respects, may often be derived from the neighbouring residences, especially as to climate, weather, springs, rivulets, roads, markets, and many other similar particulars; though they can mostly be ascertained with little trouble in other ways.

In regard to the next point, it is of very great importance, as the effect depends much upon it. Where the surfaces are only gently varied, some of the highest eminences may be mostly fixed upon for this purpose. But where they are varied in a high degree, and where a number of hills are within the proposed space: if such hills slope gently, some of their sides may commonly be selected for this use; or, when they are very steep, it may be upon some gentle rising or eminence near their bottom parts. Occasionally, where rivers pass through the grounds, it may be on some of their banks, where they are rendered interesting either by rocks, bends, or other similar means. Where there are lakes, the margins of them may be proper for the purpose, as producing good effects in such cases; and the rocky margins of the sea, in some instances, may be very suitable. Many other appropriate situations for this purpose might be noticed, but these may shew the nature of striking ones, and the means of selecting them.

The proper accomplishment of this object is very material, as any error in it may be highly injurious in various ways; while its being properly done saves expence, and at the same time affords a far superior effect, as is seen in a variety of instances.

In respect to the last matter, or that of the views towards the surrounding scenery being agreeable, it is supposed to be the best accomplished by the proper arrangement or disposition of the apartments of a residence. Where regularity is to prevail this cannot always be so easily done, but where the irregular is had recourse to, which should mostly be the case in this sort of residence, there can be little difficulty in effecting it, either by means of projections or recesses.

Thus, the breakfasting room should front a morning scene, and afford a prospect somewhat inviting to exercise throughout the day; the drawing room should have such a disposition as to display the effects of the setting sun, &c. In short, to every view, some object, it is supposed, should appear sufficiently striking to characterise it; as a hill, a spire, or some other thing of a similar nature; as, unless this be the case, too trifling an impression is left upon the mind. All

these matters, it is supposed, are the best decided upon the particular spots where they should be marked out and left for the observations of others, with the view of their being afterwards finally settled. They should never be determined upon in the closet of the designer.

In forming residences of this nature, the style of the buildings should, in some measure, it is thought, be adapted to, or regulated by, the nature of the place, and the general growth of the trees in it; the forms of the particular trees which may be peculiar to it; the general character of the surrounding scenery; and the colour of the rocks, as well as of the ground. It is found that the more common sorts of trees, in their natural growth, whether single or in groups, deviate a little in their general form, and the delicacy of their parts, according as their situation may be. Thus, where much exposed, they are mostly broad and low, being more hardy, rough, and picturesque, than when covered with young shoots, which are comparatively soft, fresh, and beautiful. In high rocky spots and exposures, trees are much broken, or divided into parts, and distant from each other, but apparently firmly attached to the place; these are harder than others, with much less softness and beauty. In low fertile plains, trees are mostly large and erect, throwing out their branches on all sides; the foliage is full and fresh; and the whole outline round, full, and flowing. When single in this sort of situation, the balance of the branches in the trees is better preserved, than in the contrary cases. Where vallies are confined between hills, trees grow high and upright, rarely broad, or putting forth many horizontal branches: the growth is quick; the shoots and foliage are tender and delicate; the trunk comparatively slender; and the whole trees more elegant and capable of graceful motions than in any of the former situations or aspects.

It is supposed that these different circumstances in the growth of trees may easily suggest styles of building somewhat analogous in their general magnitude, height, and finishing. On rocky exposed spots, where trees grow low and irregular; low irregular edifices in the castle style may be raised. In vallies, where they grow high and elegant, houses in the tower style, which implies much height, should commonly be had recourse to. In rich extended plains, buildings of the Grecian order, or such as are in a more massy and regular style than the others, should be formed. "This mode is," it is said, "certainly deserving of attention, were it for no other reason than that the trees might group well with the buildings; that when full grown they might neither be too large, nor too small; that they might neither diminish it into insignificance, nor leave it staring through trees, which, from want of due proportion to it, appear as copse-wood." Many instances of these different evils are to be met with in different places.

And it is noticed, that this mode of fixing on the style of residences of this kind must be attended to, though trees be not growing on the situations at the time of forming and raising them. This is to be determined in such cases, by the nature of the climate and the qualities of the soil, as the growth of trees chiefly depends upon them.

With regard to the forms of trees, most places are capable of affording common ones, such as oaks, elms, beeches, and others of similar kinds. But there are many spots, where residences of this sort may be formed, that are only capable of raising certain descriptions to the state of trees. This frequently occurs in hilly and maritime situations; which therefore require the particular attention of the designer; as the kinds of trees that suit them are so very different from the ordinary sort, that if he were to be attempting to group

with oaks and beeches, he might be grievously disappointed, as not any would probably grow, but spiry larches, dark Scotch firs, birches, and mountain ash, or perhaps only ivy and elder. This may furnish a variety of useful hints to the designer, as well as others.

The general character of the surrounding scenery is equally deserving of attention as the trees, and should concur in deciding on the style of the residence. It is a common notion that buildings should form strong contrasts to the works of nature, from which various styles of them have been suggested under different circumstances; but more full inquiry will shew that very sudden contrasts are not found in general nature, though they may accidentally occur in some cases, consequently that they are highly improper to be used in this way.

With respect to the colour of the rocks, and the ground, it is said, that, not merely the general forms of the surface, but the appearances of the soil and the rocks, should deserve attention, as contributing greatly to promote the principle of harmony. The tints of rocks, stones, gravel, and the soil, are mostly the same in one part of the country. Where they agree with the colour of the residence, the effect must, it is supposed, be singularly happy, as seen in the works of painters, as well as in the ancient residences of the country kind. But where they disagree, it must be disgusting, as is seen in many cases of white-washing buildings in rocky situations. This furnishes hints which may be useful in managing that process to the most advantage in other cases; and others are likewise thrown out upon different matters, which are equally useful. But the designer is cautioned against carrying these, or any other notions, into the extreme, contrary to the common practice; as where the expression of gaiety, or striking beauty, is desirable, no reasons suggested from the colour of the rocks or soil are intended to hinder the production of these characters, if in general harmony with what surrounds them.

There are many other matters which relate to the subject, that are forcibly pointed out, and the means of executing them well explained, in the work alluded to above, such as the methods of uniting residences of this sort with the grounds by means of the offices and appendages of other kinds; and with the surrounding country or scenery by the former, as well as by architectural appendages principally of the ornamental description. Also as to the modes of executing and finishing them.

More full information on the whole of this subject may be obtained from the above treatise, and the writings of Knight, Price, and others on the same head.

**RESIDENT**, a public minister, who manages the affairs of a king in the court of a prince, or petty state; or the affairs of a prince, or petty state, in the court of a king or prince.

Thus, the king of England has residents in the courts of the electors, and other princes of Germany and Italy; at the republics of Genoa and Lucca; and they, reciprocally, have residents in the court of Great Britain.

Residents are a class of public ministers inferior to ambassadors and envoys; but, like them, they are under the protection of the law of nations.

The resident does not represent the prince's person in his dignity, but only in his affairs. His representation is in reality of the same nature as that of the envoy; and he is accordingly, together with the envoy, often termed a minister of the second order; and thus the public ministers are distinguished only into two classes; ambassadors, who have the representative character, so termed by way of

excellence, and all the ministers who are not invested with that eminent character.

**RESIDENT**, *Residens*, in our *Ancient Customs*, was a tenant who was obliged to reside on his lord's land, and not to depart from the same, called also *homme levant* and *couchant*, and in Normandy *ressant du fief*.

“Quantumque de aliis tenent, ei magis obnoxius est; & ejus residens esse debet, cujus legius est.” Leg. H. I.

**RESIDENTIARY**, **RESIDENTIARIUS**, a canon installed to the privileges and profits of residence.

**RESIDUAL ANALYSIS**, is a branch of algebra invented by Landen, and applied to the solution of those problems usually solved by means of the differential and integral calculus, or the direct and inverse method of fluxions; by which the ingenious author thought to be able to avoid the objections generally made to the new calculus under either of the above forms. With regard to the fluxional process, he thought it more free from objection than the differential calculus; although many important ones might be discovered in it. However natural, says the author, it may be, in certain problems, to consider such magnitudes as enter therein, to be generated by motion, it seems very unnatural to bring motion into consideration in the solution of questions purely algebraical. Nor does it seem natural in the solution of problems concerning the motion of bodies, to superinduce imaginary motions, and thereby bring into consideration the velocity of time, the velocity of velocity, &c.; nor yet does it appear more natural, in the resolution of other problems, to make use of the fluxionary method, when (as is most commonly the case in that doctrine) the fluxions introduced into the process can, only in a figurative sense, be said to be the velocities of increase of the quantities called their fluents; such figurative expressions not being the natural language of analytics, but frequently, instead of conveying clear and distinct ideas, are confusedly employed in treating of quantities as generated by motion, which in reality cannot be conceived to be so generated. That these are legal objections to the doctrine of fluxions we are not disposed to deny; but it is now generally admitted, that the defect of the fluxionary calculus is by far less than that which has place in the residual analysis, which M. Landen was desirous of substituting for it. Indeed, we believe its defects were so obvious, that few, if any, mathematicians were induced to make it the foundation of any of their investigations; and it would, therefore, be useless for us to occupy our pages in explaining the principles on which the author rested his calculus. We shall, therefore, merely observe, that in this analysis, a geometrical or physical problem is reduced to another purely algebraical; and the solution is then obtained without any supposition of motion, and without considering quantities as composed of infinitely small particles.

Instead of finding the fluxion of a variable quantity, in the residual analysis, the author proceeds by taking the difference of the same function of the variable, in two different states of that quantity, and expressing the relation of this difference to the difference between the two states of the variable quantity itself. This relation, being first expressed generally, is then considered in the case in which the difference of the two states of the variable quantity is equal to zero.

Thus when, in the fluxionary calculus, it would be necessary to find the fluxion of such a quantity  $v^m$ , which is

$$\frac{m}{r} v^{\frac{m-r}{r}} v, \text{ M. Landen takes the quotient of } \frac{v^m - w^m}{v - w},$$

when

when  $v = w$ , and finds it to be  $\frac{m}{r} v^{\frac{m-r}{r}}$ , as above; and in the same manner he determines what is commonly called the fluxions of  $a^x$ ,  $x^r$ ,  $\log. x$ , &c.

The first book of the residual analysis was published in 1764, which contains its application to a variety of algebraical inquiries, and in determining the tangents, evolutes, ordinates, points of contrary flexure, double and triple points, &c. And in the second book it was intended to shew its application in a variety of mechanical and physico-geometrical inquiries; but, for some reason not known, that book was never published.

**RESIDUAL Figure**, in *Geometry*, the figure remaining after subtraction of a lesser from a greater.

**RESIDUAL Root**, is a root composed of two parts or members, only connected together with the sign  $-$ .

Thus,  $a - b$ , or  $5 - 3$ , is a residual root; and is so called, because its true value is no more than its residue, or difference between the parts  $a$  and  $b$ , or  $5$  and  $3$ .

**RESIDUARY LEGATEE**. See **LEGATEE**.

**RESIDUE**, **RESIDUUM**, the remainder or reliqua of an account, debt, or obligation.

**RESIDUUM of a Charge**, in *Electricity*, first discovered by Mr. Galath, in Germany, in 1746, is that part of the charge that lay on the uncoated part of a Leyden phial, which doth not let go all its electricity at once; so that it is afterwards gradually diffused to the coating.

**RESIDUUM of an Intestate's Effects**. See **INTESTATE**. See also **EXECUTOR**, and **Residuary LEGATEE**.

**RESIGNATION**, in *Ethics*, is a moral virtue, which superadds to patience a submissive disposition, respecting the intelligent cause of our uneasiness. It acknowledges both the power and the right of a superior to afflict: it is usually connected with a confidence in his justice, and indulges a hope also in some future exemption, and thus it opposes a fretful repining temper of mind.

**RESIGNATION**, *Resignatio*, in the *Canon Law*, the surrender or giving up of a benefice into the hands of those from whom it was received.

Resignation is of equal import with *surrender*; only the former is restrained to spiritual benefices, and the latter to temporal offices or employments.

It is a maxim in the ecclesiastical law, that all resignations must be made to some superior (Gibf. 822.); therefore a bishop must resign, not to the dean and chapter, but to his metropolitan, from whom he received confirmation and consecration; but the archbishop can resign to none but the king himself.

Resignation must be made to the next immediate superior, and not to the mediate; as of a church presentative to the bishop, and not to the metropolitan. (2 Roll. Abr. 358.) Donatives are not resignable to the ordinary, but to the patron who hath power to admit; and if there be two patrons of a donative, and the incumbent resign to one of them, it is good for the whole. Regularly, resignation must be made in person, and not by proxy. It is usually done either by personal appearance before the ordinary, or elsewhere before a public notary, by an instrument directed immediately to the ordinary, and attested by the said notary, in order to be presented to the ordinary by a proper person, who may pray his acceptance. No resignation can be valid, till accepted by the proper ordinary; that is, no person appointed to a cure of souls can quit that cure, or discharge himself of it, but upon good motives, to be approved by the superior who committed it to him; for it may be, that he would quit it for money, or to live idly, or the like. Nor is there any pretence to say, that the ordinary is

obliged to accept; since the law hath appointed no known remedy if he will not accept, any more than he will not ordain. 1 Still. 334.

Lindwood makes a distinction in this case, between a cure of souls, and a sine-cure. The resignation of a sine-cure, he thinks, is good immediately, without the superior's consent; because none but he that resigneth hath interest in that case: but where there is a cure of souls, it is otherwise, because not he only hath interest, but others also unto whom he is bound to preach the word of God; wherefore, in this case, it is necessary that there be the ratification of the bishop, or of such other person as hath power by right or custom to admit such resignation. (Gibf. 823.) After acceptance of the resignation, lapse shall not run but from the time of notice given. The church, indeed, is void immediately upon acceptance, and the patron may present, if he please; but as to lapse, the general rule that is here laid down is the general doctrine of all the books: inasmuch that if the bishop, who accepted the resignation, dies before notice given, the six months shall not commence till notice is given by the guardian of the spiritualities, or by the succeeding bishop, with whom the act of resignation is presumed to remain. Gibf. 283.

Resignations are either *simple* or *conditional*.

**RESIGNATIONS, Simple or Pure**, are those by which the incumbent strips himself of all his right, absolutely, and without any conditions, or reserve of pension. These are made to the bishop, or ordinary.

By the 31 Eliz. cap. 6. § 8. if any incumbent of any benefice, with cure of souls, shall corruptly resign the same, or corruptly take for, or in respect of resigning the same directly or indirectly, any pension, sum of money, or other benefit whatsoever; as well the giver, as the taker, shall lose double the value of the sum given or received; half to the queen, and half to him that shall sue for the same. Before the statute, the bishop, in cases of resignation, might, and did frequently, assign a pension, during life, out of the benefice resigned, to the person resigning. But by the aforesaid act, no pensions whatsoever can be reserved. But a man may bind himself by bond to resign, and it is not unlawful. For bonds of resignation, see **SIMONY**.

**RESIGNATIONS in Favour**, or *Conditional Resignations*, are such as are only made on condition that such other persons should be invested with them; so that the resignations are null, unless the conditions be punctually executed. These resignations *in favorem* are not of above two hundred and fifty years standing. Strong opposition was at first made to them, they being esteemed a kind of succession or transmutation of benefices, as of patrimonies belonging to a family. Accordingly, these resignations are not made into the hands of the ordinary, or collator, as pure resignations are, but to the collator paramount, who in the Romish church is the pope; there being a suspicion of simony or other unlawful paction therein, where admitted of in prejudice to the lay patron.

**RESIGNEE**, in *Law*, the party to whom a thing is resigned.

**RESINS**, in *Chemistry* and the *Arts*, peculiar inflammable compounds, furnished by some vegetables, and in some cases by animals.

Agreeably to what we have observed under **OILS**, all bodies coming under the head of the latter, although perfect liquids in their ordinary state, are susceptible of a solid form, by long exposure to the air, and more speedily by exposure to bodies furnishing oxygen with facility. Those oils we term fat oils, such as olive, spermaceti, rape, &c. by treating with nitric acid, become solid like tallow, and possess

possess similar properties. The oils termed *drying*, such as linseed and nut-oil, by the presence of oxygen, assume a solid form, unlike the greasy substance afforded by the fat oils, and more like horn, or elastic gum (caoutchouc.) The volatile oils are susceptible of the same change, from liquidity to solidity, by the agency of oxygen; the result being resins, which differ from each other in nothing material, excepting their degrees of solidity, and their peculiar odour. If we are to conclude that every essential or volatile oil is capable of being converted into a resin, which is highly probable, the number of resins will be very great. Indeed the known species are vastly too numerous for our notice in this place: we shall, therefore, confine our attention to a few of the most particular resins, especially those which are valuable in the arts, and in medicine. Dr. Thomson gives the following list of resins, with the names of the vegetables from which they are obtained.

1. Turpentine of Chio, from the pistacia terebinthus.
2. Venice turpentine.
3. Strasburgh turpentine, from the common fir.
4. Pitch, from the pinus picea.
5. Elemi, from the amyris elemifera.
6. Mastic, from the pistacia lentiscus.
7. Sandarach, from the juniper.
8. Guaiac, from the guaiacum officinale.
9. Laudanum, from the cistus ladaniferus.
10. Dragon's blood, from the dracena draco.
11. Balsam of Mecca, from the amyris opobalsamum.
12. Balsam of Copahu, from the copaifera officinalis.

To these may be added,

13. Balsam of Canada, from the pinus balsamea.
14. Guaiacum, from the lignum vitæ.
15. Copal, from the copallinum of North America.

Some of the resins are combined with benzoic acid, by which their properties are altered: of these are benzoin, balsam of Tolu, balsam of Peru, and storax.

Another class of these bodies are combined with gum, and hence have been called *gum resins*: of these are olibanum, galbanum, scammony, allasœtida, myrrh, ammoniac, aloes, and opium. They admit of analysis, either by separating the resinous part by alcohol, or the gummy part by water.

These latter substances are used in medicine. Some of the first class, or the pure resins, are used as cements; and their solution in alcohol constitutes a variety of useful varnishes.

Those resins which are distinguished by the name of balsams are said to be such as contain benzoic acid. It appears, however, they have also been distinguished for their liquidity, and from their excess of odour; so that at present the phrase appears to be very indefinite. See BALSAM.

The resins are of various degrees of consistence and hardness. The balsams of Canada and Mecca are thickish fluids: the former is often so liquid as to be spread with a brush, and is sometimes used for varnishing pictures. It gradually hardens, on exposure to the air, and ultimately may be rubbed with the hand without soiling.

Others of the resins become hard with very little exposure to the air, and are found in hard tears, sticking to the tree which affords it: of these are mastic, sandarach, and copal. Those which do not easily become solid may be obtained in that form, by distilling off the thin part. Resin and pitch are obtained in this way: the former is obtained by distilling turpentine, the latter by distilling tar. Tar is no other than turpentine contaminated with the soot, which is produced by the partial combustion employed for its extraction from the wood.

All the resins become harder by exposure to a moderate heat. It is upon this fact that the art of the japanner depends. If the surface to be japanned be covered with common tar only, and exposed to the temperature of 300° for a length of time, the coating becomes hard and infusible. At the same temperature, any other resin applied in the same way, would assume a similar hardness.

Some animals and minerals, as well as the vegetables, afford resins, or bodies very analogous to them. The concrete part of the bile of animals has most of the properties of a resin, and shell-lac is furnished from the insect called *coccus lacca*.

Ear-wax is also found to have the properties of a resin: and the substances well known as perfumes, castor, civet, and musk, are no other than animal resins. For the particular application of resins to *varnishing* and *japanning*, see those articles.

Resins are employed for many purposes. Those of the cheapest kind are used for torches, and to cover the outsidings of ships and boats. The fine transparent resins compose varnishes. Many of them are employed medicinally: such are those which enter into the composition of ointments and plasters; or internally, as the resins of scammony, jalap, and turpeth, which are purgative. Other resins, the smell of which is agreeable, as benjamin and storax, are employed as perfumes.

RESIN, *Elastic*. See CAOUTCHOUC.

RESIN, *Mastic*. See MASTIC.

RESISTANCE, or RESISTING FORCE, in *Physics*, any power which acts in opposition to another, so as to destroy or diminish its effect.

Of resistance there are various kinds, arising from the various natures and properties of the resisting bodies, and governed by various laws: as the resistance of solids, the resistance of fluids, the resistance of the air, &c.

RESISTANCE of Solids, in *Mechanics*, is the force with which the quiescent parts of solid bodies oppose the motion of others contiguous to them.

Of this there are two kinds. The first, where the resisting, and the resisted parts, *i. e.* the moving and quiescent bodies, are only contiguous, and do not cohere; *i. e.* where they constitute separate bodies or masses.

This is what M. Leibnitz calls *resistance of the surface*; but which is now more commonly denominated friction; for the laws of which, see FRICTION.

The second case of resistance is where the resisting and resisted parts are not only contiguous, but cohere; *i. e.* are parts of the same continued body or mass; for the phenomena and laws of which, see COHESION.

To which we may also add, the resistance which takes place between surfaces of solids, when completely in contact, though not forming one and the same body, or the resistance they offer to separation, the particulars of which are treated of under the article ADHESION.

RESISTANCE of the Fibres of solid Bodies, *Theory of the*. To form an idea of this resistance or tenacity of the parts, suppose a cylindrical body suspended vertically by one end. Here all its parts, being heavy, tend downwards, and endeavour to separate the two contiguous planes, where the body is the weakest; but all the parts resist this separation by the force with which they cohere, or are bound together. Here then are two opposite powers; *viz.* the weight of the cylinder, which tends to break it; and the force of cohesion of the parts, which resists the fracture.

If the base of the cylinder be increased without increasing its length, it is evident the resistance will be increased in the same ratio as the base; but the weight also increases in the same ratio: whence it is evident, that all cylinders of the

## RESISTANCE.

same matter and length, whatever their bases may be, have an equal resistance, when vertically suspended.

But if the length of the cylinder be increased, without increasing its base, its weight is increased, while the resistance or strength remains the same: consequently it is weakened by its additional length, and has a greater tendency to break.

Hence, to find the greatest length a cylinder of any matter may have, to break with its own weight; it is only necessary to know what weight is just sufficient to break another cylinder of the same base and matter: for the length of the required cylinder must be such, that its weight may be equal to the weight of the first cylinder, together with the additional weight that was employed in producing the separation.

Thus let  $l$  denote the first length of the cylinder,  $c$  its weight,  $g$  the given weight the lengthened cylinder is to bear, and  $\tau$  the least weight that breaks the cylinder  $l$ ,

also  $x$  the length sought: then as  $l : x :: c : \frac{cx}{l}$  = the

weight of the longest cylinder; and this, together with the given weight  $g$ , must be equal to  $c + \tau$ : hence

then,  $\frac{cx}{l} + g = c + \tau$ ; or  $x = \frac{c + \tau - g}{c} l$  = the

length sought. When the cylinder is just to break with its own weight only, then  $g = 0$ , and the expression is simply

$$x = \frac{c + \tau}{c} l.$$

If one end of the cylinder were fixed horizontally into a wall, and the rest suspended thence, its weight and resistance would then act in a different manner; and if it be broke by the action of its weight, the rupture would be at the end fixed into the wall. A circle or plane contiguous to the wall, and parallel to the base, and consequently vertical, would be detached from the contiguous circle within the plane of the wall, and would descend. All the motion is performed on the lowest extremity of the diameter, which remains immovable, while the upper extremity describes a quadrant of a circle, and till the circle, which before was vertical, become horizontal; *i. e.* till the cylinder be entirely broken.

In the fracture of the cylinder it is visible two forces have acted, and the one has overcome the other: the weight of the cylinder, which arose from its whole mass, has overcome the resistance which arose from the largeness of the base; and as the centres of gravity are points in which all the forces, arising from the weights of the several parts of the same bodies, are conceived to be united, one may conceive the weight of the whole cylinder applied in the centre of gravity of its mass, *i. e.* in a point in the middle of its axis: and the resistance of the cylinder applied in the centre of gravity of its base, *i. e.* in the centre of the base; it being the base which resists the fracture.

When the cylinder breaks by its own weight, all the motion is on an immovable extremity of a diameter of the base. This extremity, therefore, is the fixed point of a lever, whose two arms are the radius of the base, and half the axis; and, of consequence, the two opposite forces do not only act of themselves, and by their absolute force, but also by the relative force they derive from their distance with regard to the fixed point of the lever.

Hence it evidently follows, that a cylinder, *e. gr.* of copper, which, vertically suspended, will not break by its own weight, if less than four hundred and eighty fathom long, will break with a less length in an horizontal situation; because the length, in this latter case, contributes

two ways to the fracture; both as it makes it of such a weight, and as it is an arm of a lever to which the weight is applied. Hence, also, the smaller the base is, the less length or weight will suffice to break it; both because the resistance is really less, and because it acts by a less arm of a lever.

Hence, to find the length a prism will bear, when fixed in an horizontal position, before it breaks, either by its own weight, or by the addition of any adventitious weight; take any length of such a prism, and load it with weights till it break; then put

- $l$  = the length of this prism,
- $c$  = its weight,
- $\tau$  = the weight that breaks it,
- $a$  = the distance of the weight  $\tau$ ,
- $g$  = any given weight to be borne,
- $d$  = its distance,
- $x$  = the length required to break it.

Then  $l : x :: c : \frac{cx}{l}$ , the weight of the prism  $x$ ; and

$\frac{cx}{l} \times \frac{1}{2} x = \frac{cx^2}{2l}$  = its momentum; also  $dg$  = the mo-

mentum of the weight  $g$ ;  $\frac{cx^2}{2l} + dg$  = momentum of the

prism  $x$ , and its additional weight  $g$ .

In like manner we have  $\frac{1}{2} cl + a\tau$ , for the momentum of the shorter prism, together with the weight  $\tau$ .

Consequently we obtain the following equation:

$$\frac{cx^2}{2l} + dg = \frac{1}{2} cl + a\tau;$$

from which is found  $x = \sqrt{\frac{(a\tau + \frac{1}{2} cl - dg) 2l}{c}}$ , the

length sought, or that by which the cylinder will break with the weight  $g$ , at the distance  $d$ . If this last weight be nothing, or the length be required when the cylinder would just break with its own weight, then we shall have  $dg = 0$ ,

and the expression becomes simply  $x = \sqrt{\frac{(a\tau + \frac{1}{2} cl) 2l}{c}}$ .

If two cylinders of the same matter, having their bases and lengths in the same proportion, be suspended horizontally; it is evident, that the greater has more weight than the lesser, both on account of its length, and of its base. But it hath less resistance on account of its length, considered as a longer arm of a lever, and has only more resistance on account of its base; therefore it exceeds the lesser in its bulk and weight more than in resistance, and consequently it must break more easily.

Hence, we see why, upon making models and machines in small, people are apt to be mistaken as to the resistance and strength of certain horizontal pieces, when they come to execute their designs in large, by observing the same proportion as in the small. Galileo's doctrine of resistance, therefore, is no idle speculation, but becomes applicable in architecture, and other arts.

The weight required to break a body, placed horizontally, being always less than that required to break it in a vertical situation; and this weight being to be greater or less, according to the ratio of the two arms of the lever, the whole theory is always reducible to this: *viz.* to find what part of the absolute weight the relative weight is to be, supposing the figure of the body known; which indeed is necessary, because it is the figure that determines the two centres of gravity, or the two arms of the lever. For if the body,

*e. gr.*

*c. gr.* were a cone, its centre of gravity would not be in the middle of its axis, as in the cylinder; and, if it were a semi-parabolical solid, neither would its centre of gravity be in the middle of its length or axis, nor the centre of gravity of its base in the middle of the axis of its base. But still, wheresoever these centres fall in the several figures, the two arms of the lever are estimated accordingly.

It may be here observed, that if the base, by which the body is fastened into the wall, be not circular, but, *c. gr.* parabolical, and the vertex of the parabola be at the top, the motion of the fracture will not be on an immoveable point, but on a whole immoveable line; which may be called the *axis of equilibrium*; and it is with regard to this that the distances of the centres of gravity are to be determined.

Now, a body horizontally suspended, being supposed such as that the smallest addition of weight would break it, there is an equilibrium between its positive and relative weight; and of consequence those two opposite powers are to each other reciprocally as the arms of the lever to which they are applied. On the other hand, the resistance of a body is always equal to the greatest weight which it will sustain in a vertical situation, without breaking, *i. e.* is equal to its absolute weight. Therefore, substituting the absolute weight for the resistance, it appears that the absolute weight of a body, suspended horizontally, is to its relative weight as the distance of its centre of gravity from the axis of equilibrium is to the distance of the centre of gravity of its base from the same axis.

The discovery of this important truth, at least an equivalent to it, and to which this is reducible, we owe to Galileo. From this fundamental proposition are easily deduced several consequences; as, for instance, that, if the distance of the centre of gravity of the base from the axis of equilibrium be half the distance of the centre of gravity of the body, the relative weight will only be half the absolute weight; and that a cylinder of copper, horizontally suspended, whose length is double the diameter, will break, provided it weigh half what a cylinder of the same base, 4801 fathoms long, weighs.

On this theory of resistance, which we owe to Galileo, M. Mariotte made a very ingenious remark, which gave birth to a new system. Galileo supposes, that, where the body breaks, all the fibres break at once; so that the body always resists with its whole absolute force, or with the whole force that all its fibres have in the place where it is to be broke. But M. Mariotte, finding that all bodies, even glass itself, bend before they broke, shews that fibres are to be considered as so many little bent springs, which never exert their whole force till stretched to a certain point, and never break till entirely unbent. Hence, those nearest the axis of equilibrium, which is an immoveable line, are stretched less than those farther off; and, of consequence, employ a less part of their force.

This consideration only takes place in the horizontal situation of the body: in the vertical, the fibres of the base all break at once; so that the absolute weight of the body must exceed the united resistance of all its fibres; a greater weight is, therefore, required here than in the horizontal situation; that is, a greater weight is required to overcome their united resistance, than to overcome their several resistances one after another. The difference between the two situations arises hence, that, in the horizontal, there is an immoveable point or line, as a centre of motion, which is not in the vertical.

Varignon has improved on the system of M. Mariotte, and shewn, that, to Galileo's system, it adds the consideration of the centre of percussion. The comparison of the

centres of gravity with the centres of percussion afford a fine view, and set the whole doctrine in a most agreeable light.

In each system, the base, by which the body breaks, moves on the axis of equilibrium, which is an immoveable line in the same base; but in the second, the fibres of this base are continually stretching more and more, and that in the same ratio as they recede farther and farther from the axis of equilibrium; and, of consequence, are still exerting a greater and greater part of their whole force.

These unequal extensions, like all other forces, must have some common centre where they all meet, and with regard to which they make equal efforts on each side; and as they are precisely in the same proportion as the velocities which the several points of a rod moved circularly would have to one another, the centre of extension of the base, by which the body breaks, or tends to break, must be the same with its centre of percussion. Galileo's hypothesis, according to which the fibres are supposed to stretch equally, and break all at once, corresponds to the case of a rod moving parallel to itself, where the centre of extension or percussion does not appear, as being confounded with the centre of gravity.

The base of fracture being a surface, whose particular nature determines its centre of percussion, it is necessary that this should be first known, to find on what point of the vertical axis of that base it is placed, and how far it is from the axis of equilibrium. Indeed, we know in the general, that it always acts with so much the more advantage as it is farther from it; because it acts by a longer arm of a lever; and of consequence it is the unequal resistance of the fibres in M. Mariotte's hypothesis, which produces the centre of percussion; but this unequal resistance is greater or less, according as the centre of percussion is placed more or less high on the vertical axis of the base, in the different surfaces of the base of the fracture.

To express this unequal resistance, accompanied with all the variation it is capable of, regard must be had to the ratio between the distance of the centre of percussion from the axis of equilibrium, and the length of the vertical axis of the base. In which ratio, the first term, or the numerator, is always less than the second, or the denominator; so that the ratio is always a fraction less than unity; and the unequal resistance of the fibres in M. Mariotte's hypothesis is so much the greater, or, which amounts to the same, approaches so much nearer to the equal resistance in Galileo's hypothesis, as the two terms of the ratio are nearer to an equality.

Hence it follows, that the resistance of bodies in M. Mariotte's system is to that in Galileo's, as the least of the terms in the ratio is to the greatest. Hence, also, the resistance being less than what Galileo imagined, the relative weight must also be less; so that the proportion already mentioned between the absolute and relative weight cannot subsist in the new system, without an augmentation of the relative weight, or a diminution of the absolute weight; which diminution is had by multiplying the weight by the ratio, which is always less than unity. This done, we find that the absolute weight, multiplied by the ratio, is to the relative weight, as the distance of the centre of gravity of the body from the axis of equilibrium, is to the distance of the centre of gravity of the base of the fracture from the same axis: which is precisely the same thing with the general formula given by M. Varignon for the system of M. Mariotte. In effect, after conceiving the relative weight of a body, and its resistance equal to its absolute weight, as two contrary powers applied to the two arms of a lever, in the hypothesis of Galileo, there needs nothing to convert it into

into that of M. Mariotte, but to imagine that the resistance, or the absolute weight, is become less, every thing else remaining the same.

One of the most curious, and perhaps the most useful questions in this research, is to find what figure a body must have, that its resistance may be equal in all its parts, whether it be loaded with an additional weight, or as only sustaining its own weight.

To this end it is necessary that some part of it should be conceived to be cut off by a plane parallel to the fracture, so that the momentum of the part retrenched, be to its resistance in the same ratio as the momentum of the whole is to its resistance. These four powers act by arms of levers peculiar to themselves, and are proportional in the whole, and in each part, of a solid of equal resistance. From this proportion Varignon deduces two solids, which shall resist equally in all their parts, or be no more liable to break in one part than in another. Galileo had previously found one of these, which is that in which the sides are parabolical: the other, found by Varignon, is in the form of a trumpet, which is to be fixed into the wall by its greater end; so that its magnitude or weight is always diminished in proportion as its length, or the arm of the lever by which it acts, is increased. It is remarkable, that, however different the two systems may be, the solids of equal resistance are the same in both.

We cannot pursue the theory of resistances to a greater length in the present article; but shall confine ourselves to exhibiting a general synopsis of the most important results which have been drawn by different writers on this subject, both practical and theoretical.

1. The resistance of a beam, or bar, to a fracture, by a force acting laterally, is as the solid made by a section of the beam in the place where the force is applied, into the distance of its centre of gravity from the point or line where the breach will end.
2. In square beams, the lateral strengths are as the cubes of their breadths or depths.
3. In cylindric beams, the resistances or strengths are as the cubes of the diameters.
4. In rectangular beams, the lateral strengths are conjointly as the breadths and squares of the depths.
5. The lateral resistances of any beams, whose sections are similar figures and alike placed, are as the cubes of the like dimensions of those figures.
6. The lateral strength of a beam, with its narrower face upwards, is to its strength with the broader face upwards, as the breadth of the broader face to the breadth of the narrower.
7. The lateral strengths of prismatic beams of the same materials, are as the areas of the sections, and the distance of their centre of gravity, directly, and as their lengths and weights reciprocally.
8. When the beam is fixed at both ends, the same property has place, except that, in this case, we must consider the beam as only half the length of the former.
9. Cylinders and square prisms have their lateral strengths proportional to the cubes of their diameters, or depths, directly, and their lengths and weights inversely.
10. Similar prisms and cylinders have their strength inversely proportional to their linear dimensions.

For other propositions relative to the resistance or strength of beams of various forms and in various positions, see the article *STRENGTH and Strefs of Materials*.

The following results are wholly drawn from experiments on different substances, by Emerfon and other writers, by means of which the propositions stated in

the preceding part of this article may be submitted to computation.

The relative Resistances or Strengths of Wood and other Bodies.

	Proportional Resistance.
Box, yew, plum-tree, oak	11
Elm, ash	$8\frac{1}{2}$
Walnut, thorn	$7\frac{1}{2}$
Red fir, hollin, elder, plane crab-tree, apple-tree	7
Beech, cherry-tree, hazel	$6\frac{3}{4}$
Alder, asp, birch, white fir, willow	6
Iron	107
Brass	50
Bone	22
Lead	$6\frac{1}{2}$
Fine free-stone	1

A cylindric rod of good clean fir, of an inch circumference, drawn in length, will bear at its extremity 400 lbs.; and a spear of fir, of two inches diameter, will bear about seven ton weight. A rod of good iron, of an inch circumference, will bear nearly three ton weight. A good hempen rope, of an inch circumference, will bear 1000 lbs. at its extremity. Hence Emerfon concludes, that if a rod of fir, or a rope, or a rod of iron, of  $d$  inches diameter, were to lift a quarter of the extreme weight that they would support, then

The fir would bear  $8\frac{1}{2} d^2$  hundred weight.  
 The rope -  $22 d^2$  ditto.  
 The iron -  $6\frac{3}{4} d^2$  tons.

To these results we may add, from the experiments and investigations of professor Robison, that a prism of white marble, an inch square and a foot long, bears about 500 lbs. And that, from the various authors he has collected, the cohesive force of a square inch of gold, when cast, is about 20,000 lbs.; of silver, 40,000 lbs.; cast iron from 40,000 to 60,000 lbs.; wrought iron from 60,000 to 90,000 lbs.; soft steel, 12,000 lbs.; razor steel, 15,000 lbs.; oak and beech, in the direction of their fibres, from 8000 to 17,000 lbs.; willow, 12,000 lbs.; cedar, 5000 lbs.; fir, 8000 lbs.; ivory, 16,000 lbs.; bone, 5000 lbs.; rope, 20,000 lbs. And a cylinder, an inch in diameter, loaded to one-fourth, will carry, if of iron, 135 cwt.; of rope, 22 cwt.; oak, 14 cwt.; and fir, 9 cwt.

The resistance of some metals is doubled, or tripled, by the operation of forging and wire-drawing; and the cohesive, as well as the repulsive, force of wood, is often increased by moderate compression. Oak will *suspend* much more than fir; but fir will *support* twice as much as oak; which difference is supposed to arise from the curvature of the fibres of oak; yet oak has been known to support, with safety, more than two tons for every square inch. Stone will support from 250 to 850 thousand pounds, on a foot square; brick, 300 lbs.; and sometimes they are practically made to support one-sixth as much. Stone is said to be capable of bearing a much greater weight in that position in which it is found in the quarry, than in any other position. See *STRENGTH of Materials*.

RESISTANCE of Fluids, in *Hydrostatics*, is the force with which bodies, moving in fluid mediums, are impeded and retarded in their motion.

A body moving in a fluid is resisted from two causes: the first, the cohesion of the parts of the fluid. For a body, in its motion, separating the parts of a liquid, must overcome the force with which those parts cohere.

The second is the inertia, or inactivity of matter, by which

## RESISTANCE.

which a certain force is required to move the particles from their places, in order to let the body pass.

The retardation from the first cause is always the same in the same space, the body remaining the same, whatever be the velocity, that is, the resistance is as the space run through in the same time; in which ratio the velocity also increases; and therefore the resistance from the first cause is as the velocity itself.

The resistance from the second cause, when the same body moves through different fluids with the same velocity, follows the proportion of the matter to be removed in the same time, which is as the density of the fluid.

When the same body moves through the same fluid with different velocities, this resistance increases in proportion to the number of particles struck in an equal time; which number is as the space run through in that time, that is, as the velocity. But it also increases in proportion to the force with which the body strikes against every part; which force is also as the velocity of the body; and therefore, if the velocity be triple, the resistance is triple, from a triple number of parts to be removed. It is also triple from a stroke three times stronger against every particle; therefore the whole resistance is nine-fold, that is, as the square of the velocity. Hence, a body moved in a fluid is resisted partly in a ratio of the velocity, and partly in a duplicate ratio of it.

Hence, therefore, if  $d$  denotes the density of the fluid,  $v$  the velocity of the body, and  $a$  and  $b$  constant co-efficients; then  $adv + bv^2$  will be proportional to the whole resistance to the same body, moving with different velocities, in the same direction through fluids of different densities, but of the same tenacity. But to take into consideration the different tenacities of fluids, let  $t$  denote the tenacity, or the cohesion of the parts of the fluid; then  $adv^3 + btv$  will be as the said whole resistance.

The quantity of resistance, however, arising from the cohesion of the parts of the fluids, is very trifling with respect to the other resistance, except in very glutinous ones; and it also increases in a much lower degree, being only as the velocity, while the other is as the square of the velocity. Hence then the term  $btv$  is very small, in respect of the other term  $adv^2$ , and, consequently, the resistance is nearly as the latter term, or nearly as the square of the velocity: which formula has been employed by most authors, and is, indeed, very nearly the truth in slow motions; but in very rapid ones it is far from correct, not so much from the omission of the small term  $btv$ , due to the cohesion; but from the want of the full counter pressure on the hinder part of the body, by which means a vacuum, either perfect or partial, is left behind the body in its motion; and also perhaps to some compression or accumulation of the fluid against the fore-part of the body. Therefore, in order to conceive the resistance of fluids to a body moving in them, it is necessary to distinguish between those fluids which, being compressed by some incumbent weight, perpetually close up the space behind the body in motion, without permitting, for an instant, any vacuity to remain behind it; and those fluids which, not being sufficiently compressed, the space left behind the moving body remains for some time empty. These differences, in the resisting fluids, will occasion very remarkable varieties in the laws of their resistance, and are absolutely necessary to be considered in the determination of the action of the air on shot and shells; for the air partakes of both these affections, according to the different velocities of the projected body.

In treating of these resistances, the fluids may likewise be

considered as continued or discontinued, that is, as having their particles contiguous, or as being separated and unconnected, and also as either elastic or non-elastic.

If a fluid was so constituted, that all the particles composing it were at some distance from each other, and there was no action between them, then the resistance of a body moving in it would be easily computed, from the quantity of motion communicated to these particles: for instance, if a cylinder moved in such a fluid in the direction of its axis, it would communicate to the particles it met with a velocity equal to its own, and in its own direction, supposing that neither the cylinder, nor the parts of the fluid, were elastic; whence, if the velocity and diameter of the cylinder be known, and also the density of the fluid, there would thence be determined the quantity of motion communicated to the fluid, which, action and re-action being equal, is the same with the quantity lost by the cylinder, consequently the resistance would be thereby ascertained.

In this kind of discontinued fluid, the particles being detached from each other, every one of them can pursue its own motion in any direction, at least for some time, independent of the neighbouring ones; wherefore, if instead of a cylinder, moving in the direction of its axis, a body, with a surface oblique to its direction, be supposed to move in such a fluid, the motion which the parts of the fluid will hereby acquire, will not be in the direction of the resisted body, but perpendicular to its oblique surface; whence the resistance to such a body will not be estimated from the whole motion communicated to the particles of the fluid, but from that part of it only which is in the direction of the resisted body. In fluids then, where the parts are thus discontinued from each other, the different obliquities of that surface, which goes foremost, will occasion considerable changes in the resistance; although the section of the solid, by a plane perpendicular to its direction, should in all cases be the same. And sir Isaac Newton has particularly determined, that, in a fluid thus constituted, the resistance of a globe is but half the resistance of a cylinder of the same diameter, moving in the direction of its axis with the same velocity.

But though the hypothesis of a fluid, thus constituted, be of great use in explaining the nature of resistances; yet, in reality, we know of no such fluid existing in nature; all the fluids, with which we are conversant, are so formed, that their particles either lie contiguous to each other, or at least act on each other in the same manner as if they did; consequently, in these fluids, no one particle contiguous to the resisted body can be moved, without moving at the same time a great number of others, some of which will be distant from it; and the motion thus communicated to a mass of the fluid, will not be in any one determined direction, but will in each particle be different, according to the different manners in which it lies in contact with those from which it receives its impulse; whence great numbers of the particles being diverted into oblique directions, the resistance of the moving body, which will depend on the quantity of motion communicated to the fluid in its own direction, will necessarily be different in quantity, from what it would be in the preceding supposition, and its estimation becomes much more complicated and operose.

If the fluid be compressed by the incumbent weight of its upper parts, as all the fluids are with us, except at their very surface, and if the velocity of the moving body be much less than that with which the parts of the fluid would rush into a void space, in consequence of their compression; it is evident, that in this case the space left by the moving body will be instantaneously filled up by the fluid; and the parts

## RESISTANCE.

parts of the fluid, against which the foremost part of the body presses in its motion, will, instead of being impelled forwards in the direction of the body, circulate in some measure towards the hinder part of it, thereby to restore the equilibrium, which the constant influx of the fluid behind the body would otherwise destroy; whence the progressive motion of the fluid, and consequently the resistance of the body, which depends on it, would be in this instance much less than in the hypothesis, where each particle is supposed to acquire, from the stroke of the resisting body, a velocity equal to that with which the body moved, and in the same direction. Sir Isaac Newton has determined, that the resistance of a cylinder, moving in the direction of its axis, in such a compressed fluid as we have here treated of, is but one-fourth part of the resistance which the same cylinder would undergo, if it moved with the same velocity, in a fluid constituted in the manner described in the first hypothesis, each fluid being supposed to be of the same density.

But again, it is not only in the quantity of their resistance that these fluids differ, but likewise in the different manner in which they act on solids of different forms, moving in them. In the discontinued fluid, first described, the obliquity of the foremost surface of the moving body would diminish the resistance; but in compressed fluids this holds not true, at least not in any considerable degree; for the principal resistance in compressed fluids arises from the greater or lesser facility with which the fluid, impelled by the fore-part of the body, can circulate towards its hindermost part; and this being little, if at all, affected by the form of the moving body, whether it be cylindrical, conical, or spherical, it follows, that while the transverse section of the body, and consequently the quantity of impelled fluid is the same, the change of figure in the body will scarcely affect the quantity of its resistance.

And this case, that is, the resistance of a compressed fluid to a solid, moving in it with a velocity much less than what the parts of the fluid would acquire from their compression; this case has been very fully considered by Sir Isaac Newton, who has ascertained the quantity of such a resistance according to the different magnitudes of the moving body, and the density of the fluid. But he very expressly informs us, that the rules he has laid down are not generally true, but upon a supposition that the compression of the fluid be increased in the greater velocities of the moving body: however, some unskilful writers, who have followed him, overlooking this caution, have applied his determination to bodies moving with all kinds of velocities, without attending to the different compressions of the fluids they are resisted by; and by this means they have accounted the resistance of the air to musket and cannon-shot, to be but one-third part of what it is found to be by experience.

It is indeed evident, that the resisting power of the medium must be increased, when the resisting body moves so fast that the fluid cannot instantaneously press in behind it, and fill the deserted space; for when this happens the body will be deprived of the pressure of the fluid behind it; which in some measure balanced its resistance, and must support on its fore-part the whole weight of a column of the fluid, independent of the motion it gives to the parts of the fluid; and besides, the motion in the particles driven before the body, is, in this case, less affected by the compression of the fluid, and consequently they are less deflected from the direction in which they are impelled by the resisted surface; whence this species of resistance approaches more and more to that described in the first hypothesis, where

each particle of the fluid being unconnected with the neighbouring ones, it pursues its own motion, in its own direction, without being interrupted or deflected by their contiguity; and therefore, as the resistance of a discontinued fluid to a cylinder, moving in the direction of its axis, is four times greater than the resistance of a fluid sufficiently compressed of the same density; it follows, that the resistance of a fluid, when a vacuum is left behind the moving body, may be nearly four times greater than that of the same fluid, when no such vacuum is formed; for when a void space is thus left, the resistance approaches in its nature to that of a discontinued fluid.

This, then, may probably be the case in a cylinder moving in the same compressed fluid, according to the different degrees of its velocity; so that if it set out with a great velocity, and moves in the fluid till that velocity be much diminished, the resisting power of the medium may be nearly four times greater in the beginning of its motion than in the end.

In a globe the difference will not be so great, because, on account of its oblique surface, its resistance in a discontinued medium is but about twice as much as in one properly compressed; for its oblique surface diminishes its resistance in one case, and not in the other: however, as the compression of the medium, even when a vacuum is left behind the moving body, may yet confine the oblique motion of the parts of the fluid, which are driven before the body, and as in an elastic fluid, as the air is, there will be some degree of condensation in those parts; it is highly probable, that the resistance of a globe moving in a compressed fluid may greatly exceed the proportion of the resistance to slow motions.

And as this increase of the resisting power of the medium will take place, when the velocity of the moving body is so great that a perfect vacuum is left behind it, so some degree of augmentation will be sensible in velocities much short of this; for even when, by the compression of the fluid, the space left behind the body is instantaneously filled up; yet, if the velocity with which the parts of the fluid rush in behind, is not much greater than that with which the body moves, the same reasons we have urged above, in the case of an absolute vacuum, will hold in a less degree in this instance; and therefore we are not to suppose, that, in the increased resistance which we have hitherto treated of, it immediately vanishes, when the compression of the fluid is just sufficient to prevent a vacuum behind the resisted body; but we must consider it as diminishing only, according as the velocity with which the parts of the fluid follow the body, exceeds that with which the body moves.

Hence, then, we may conclude, that if a globe sets out in a resisting medium, with a velocity much exceeding that with which the particles of the medium would rush into a void space, in consequence of their compression, so that a vacuum is necessarily left behind the globe in its motion: the resistance of this medium to the globe will be near three times greater, in proportion to its velocity, than what we are sure, from Sir Isaac Newton, would take place in a slower motion. We may also farther conclude, that the resisting power of the medium will gradually diminish as the velocity of the globe decreases, till at last, when it moves with a velocity which bears but a small proportion to that with which the particles of the medium follow it, the resistance becomes the same with what is assigned by Sir Isaac Newton in the case of a compressed fluid.

And from this determination we see how false that position is, which asserts the resistance of any medium to be in the duplicate proportion of the velocity of the resisted body;

# RESISTANCE.

body; for it is evident by what we have said, that this can only be considered as nearly true in small variations of velocity, and can never be applied in the comparing together of the resistances to all velocities whatever, without the most enormous errors. See *New Principles of Gunnery*, by Mr. Robins, chap. 2. prop. 1. See *RESISTANCE of the Air*. See also *PROJECTILE and GUNNERY*.

Resistance and retardation are used indifferently for each other, as being both in the same proportion, and the same resistance always generating the same retardation. But, with regard to different bodies, the same resistance frequently generates different retardations; the resistance being as the quantity of motion, and the retardation as that of the celerity. For the difference and measure of the two, see *RETARDATION*.

The retardations from this resistance may be compared together, by comparing the resistance with the gravity or quantity of matter. Thus, let  $v$  = the velocity;  $a$  = the area of the face, or end of a cylinder;  $n$  = the specific gravity of the fluid;  $g = 32\frac{1}{2}$  feet, the force of gravity;

then the altitude due to the velocity  $v$  being  $\frac{v^2}{2g}$ , the whole resistance, or motive force  $m$ , will be expressed by the following formulæ;

$$m = an \times \frac{v^2}{2g} = \frac{anv^2}{2g}; \text{ or } = \frac{anv^2s^3}{2g}$$

the latter having place when the motion is not in a direction perpendicular to the plane or end, but is inclined to it at a given angle, whose sine is  $s$ . For it is a known property, that, in this case, the resistance varies as the cube of the sine of the angle of inclination. If now  $w$  be made to denote the weight of the body, and  $f$  the retarding force; then, on the same principles, we derive

$$f = \frac{m}{w} = \frac{anv^2s^3}{2gw}$$

If the body be a cylinder, moving in the direction of its axis, and the diameter of the base equal  $d$ , or radius  $r$ , and  $\pi = 3.14159$ , &c. then

$$f = \frac{m}{w} = \frac{\pi n d^2 v^2}{8 g w} = \frac{\pi n r^2 v^2}{2 g w}$$

But when the cylinder moves in a direction perpendicular to its axis, then writing  $b$  for the height or length of the cylinder, we have

$$f = \frac{m}{w} = \frac{nv^2 b d}{3 g w} = \frac{nv^2 b r}{\frac{1}{2} g w}$$

And when it moves obliquely to its axis, then writing  $s$  for the sine of the angle of inclination, we have

$$f = \frac{nv^2 r b s^3}{2 g} \left\{ 1 - \frac{3s^2 - 1}{6} + \frac{3(s^2 - 1)^2}{40} + \frac{(s^2 + 5)(s^2 - 1)^2}{112} + \&c. \right\} + \frac{\pi n v^2 r^2}{2 g} (-s^2)^{\frac{3}{2}}$$

See Moore's *Theory of Military Rockets*.

If the body be a cone, then the same notation remaining, only writing  $s$  for the sine of the angle of inclination of the side of the cone; then

$$f = \frac{m}{w} = \frac{\pi n d^2 v^2 s^2}{8 g w} = \frac{\pi n r^2 v^2 s^2}{2 g w}$$

For, in this case, the inclination has no effect in reducing the section opposed to the resistance of the fluid, this being the same as in the cylinder, and therefore will vary as  $s^2$ .

The same notation still remaining, it is found, from a fluxional investigation (see Gregory's *Mechanics*, vol. i.) that the resistance of the body, when terminated with a hemispherical surface, is

$$f = \frac{m}{w} = \frac{\pi n d^2 v^2}{16 g w} = \frac{\pi n r^2 v^2}{4 g w}$$

that is, half what it is when the end is a plane surface.

Hence the resistance of a sphere, when impelled through any fluid, is equal to half the direct resistance to a great circle of it, or to a cylinder of the same diameter. Since  $\frac{1}{2} \pi d^3$  is the magnitude of the globe, if  $N$  denotes its density, or specific gravity, its weight  $w = \frac{1}{2} \pi N d^3$ ; and, therefore, the retarding force becomes

$$f = \frac{m}{w} = \frac{\pi n v^2 d^4}{16 g w} \times \frac{6}{\pi N d^3} = \frac{3 n v^2}{8 g N d} = \frac{v^2}{2 g s}$$

where  $s$  is the space described; for  $2fgs = v^2$ , by the law of accelerated or retarded motions. From which it appears, that the resistance varies as the square of the velocity directly, and as the diameter inversely, all things else being the same; and hence the reason, why a large ball overcomes resistance better than a smaller one.

James Bernouilli demonstrates the following theorems, *Acta Erud. Lips.* for June 1693, p. 252, &c.

1. If an isosceles triangle be moved in a fluid according to the direction of a line perpendicular to its base; first, with the vertex foremost, and then with its base; the resistances will be in the duplicate ratio of the base, and of the sum of the legs.

2. The resistance of a square, moved according to the direction of its side, is to the resistance of the same square, moved with the same celerity in the direction of its diagonal, as the diagonal is to the side.

3. The resistance of a circular segment, less than a semicircle, carried in a direction perpendicular to its basis, when it goes with the base foremost, and when with its vertex foremost (the same direction and celerity continuing), is as the square of the same diameter to the same, less one-third of the square of the base of the segment. Hence, the resistances of a semicircle, when its base and when its vertex go foremost, are to one another in a sesquialterate ratio.

4. A parabola moving in the direction of its axis, first with its basis, and then its vertex foremost, has its resistances as the tangent to an arc of a circle, whose diameter is equal to the parameter, and the tangent equal to half the basis of the parabola.

5. The resistances of an hyperbola and ellipsis, when the vertex and base go foremost, may be thus computed. Say, as the sum (or difference) of the transverse axis and latus rectum is to the transverse axis, so is the square of the latus rectum to the square of the diameter of a certain circle; in which circle apply a tangent, equal to half the basis of the hyperbola or ellipsis. Then say again, as the sum (or difference) of the axis and parameter is to the parameter, so is the aforesaid tangent to another right line. And farther, as the sum (or difference) of the axis and parameter is to the axis, so is the circular arc corresponding to the aforesaid tangent to another arc. This done, the resistances will be as the tangent to the sum (or difference) of the right line thus found, and the arc last mentioned.

6. In the general, the resistances of any figure whatever, going now with its base foremost, and then with its vertex, are as the figures of the base to the sum of all the cubes of the elements of the base, divided by the squares of the elements of the curve line.

## RESISTANCE.

All which rules may be of use in the construction of ships, and in perfecting the art of navigation universally; as also for determining the figures of the balls of pendulums for clocks, &c.

*RESISTANCE of Fluid Mediums to the Motion of Falling Bodies.*—A body freely descending in a fluid is accelerated by the respective gravity of the body, which continually acts upon it, yet not equally, as in a vacuum: the resistance of the fluid occasions a retardation, that is, a diminution of acceleration, which diminution increases with the velocity of the body. Now there is a certain velocity, which is the greatest a body can acquire by falling; for if its velocity be such, that the resistance arising from it becomes equal to the respective weight of the body, its motion can be no longer accelerated; for the motion here continually generated by the respective gravity, will be destroyed by the resistance, and the body forced to go on equally. A body continually comes nearer and nearer to this greatest celerity, but can never attain to it.

When the densities of a fluid body are given, the respective weight of the body may be known; and by knowing the diameter of the body, it may be found from what height a body falling in vacuo can acquire such a velocity as that the resistance in a fluid shall be equal to that respective weight, which will be that greatest velocity above-mentioned. If the body be a sphere, it is known, that a sphere is equal to a cylinder of the same diameter, whose height is two-third parts of that diameter; which height is to be increased in the ratio in which the respective weight of the body exceeds the weight of the fluid, in order to have the height of a cylinder of the fluid, whose weight is equal to the respective weight of the body; but if you double this height, you will have a height from which a body falling in vacuo acquires such a velocity as generates a resistance equal to this respective weight, and which therefore is the greatest velocity which a body can acquire, by falling in a fluid, from an infinite height. Lead is eleven times heavier than water; wherefore its respective weight is to the weight of water, as ten to one; therefore a leaden ball, as appears from what has been said, cannot acquire a greater velocity, in falling in water, than it would acquire in falling in vacuo, from a height of  $13\frac{1}{3}$  of its diameters.

A body lighter than a fluid, and ascending in it by the action of the fluid, is moved exactly by the same laws as a heavier body falling in the fluid. Wherever the body is placed, it is sustained by the fluid, and carried up with a force equal to the difference between the weight of a quantity of the fluid of the same bulk as the body, and the body itself; by which not only the action of gravity of the body is destroyed; but the body is also carried upwards by a motion equally accelerated, in the same manner as a body heavier than a fluid descends by its respective gravity: but the equality of the acceleration is destroyed in the same manner by the resistance, in the ascent of a body lighter than the fluid, as it is destroyed in the descent of a body heavier.

When a body specifically heavier than a fluid is thrown in it, it is retarded upon a double account; on account of the gravity of the body, and on account of the resistance of the fluid; consequently, a body rises to a less height than it would rise to in vacuo with the same celerity. But the defects of the height in a fluid from the height to which a body would rise in vacuo with the same celerity, have a greater proportion to each other than the heights themselves; and in less heights the defects are nearly as the squares of the heights in vacuo.

In order to submit the above principles to accurate computation, we must refer back to our preceding determination

of the retardative force of a fluid to a body moving it, which we found to be

$$f = \frac{m}{\omega} = \frac{\pi n v^2 d^3}{16 g \omega} \times \frac{6}{\pi N d^3} = \frac{3 n v^2}{8 g N d} = \frac{v^2}{2 g s};$$

from the two latter terms of which we have  $s = \frac{N}{n} \times \frac{1}{2} d$ ;

which is the space that would be described by the globe, while its whole motion is generated or destroyed by a constant force, which is equal to the forces of resistance, if no other force acted on the globe to continue its motion. And if the density of the fluid were equal to that of the globe, the resisting force is such as, acting constantly on the globe without any other force, would generate or destroy its motion in describing the space  $\frac{1}{2}d$ , or  $\frac{1}{2}$  of its diameter, by that accelerating or retarding force.

Hence the greatest velocity that a ball will acquire by descending in a fluid by means of its relative weight in that fluid, will be found by making the resisting force equal to that weight. For, after the velocity has arrived at such a degree, that the resisting force is equal to the weight that urges it, it will increase no longer, and the globe will then continue to descend with an uniform velocity.

Now  $N$  and  $n$  being the separate specific gravities of the globe and fluid,  $N - n$  will be the relative gravity of the globe in the fluid; and, therefore,  $\omega = \frac{1}{2} \pi d^3 (N - n)$

is the weight by which it is urged,  $m = \frac{\pi n v^2 d^3}{16 g}$  is the

resistance; consequently  $\frac{\pi n v^2 d^3}{16 g} = \frac{1}{2} \pi d^3 (N - n)$

when the velocity becomes uniform; whence we obtain

$$v = \sqrt{\left(2g \times \frac{1}{2} d \times \frac{N - n}{n}\right)}$$

for the uniform or greatest velocity of the globe.

Thus, for example, if a leaden ball one inch in diameter descend in water, and in air of the same density as at the earth's surface; the three specific gravities being, lead

$= 11\frac{1}{2}$ , water  $= 1$ , and air  $= \frac{3}{2500}$ ; then

$$v = \sqrt{\left(2 \times 32\frac{1}{2} \times \frac{4}{36} \times 10\frac{1}{2}\right)} = 8.5944 \text{ feet}$$

per second for the greatest velocity in water; and

$$v = \sqrt{\left(4 \times \frac{193}{12} \times \frac{4}{36} \times \frac{34}{3} \times \frac{2500}{3}\right)} = 259.82 \text{ feet}$$

per second for the greatest velocity in air.

But as this velocity, all other things being the same, varies as  $\sqrt{d}$ ; it follows that a ball of  $\frac{1}{100}$ th of an inch diameter would only acquire velocities  $\frac{1}{10}$ th of those given above. Hence it appears, how soon small bodies come to their greatest or uniform velocity in descending in fluids, and how very small that velocity is; which explains the reason of the slow precipitation of mud and small particles in water, as also why, in precipitations, the larger and gross particles descend soonest and lowest.

It appears also, from the preceding formulæ, that where  $N = n$ , or the density of the body is equal to that of the fluid; then  $N - n = 0$ , and consequently the velocity and space are in this case both equal to zero, as they ought to be.

Again, when the body is lighter than the fluid, then  $N - n$  becomes negative, and the motion and force both tend the contrary way; that is, the ball will ascend by the

## RESISTANCE.

same laws by which, in the preceding case, the heavier body descended, as stated in the preceding part of this article.

RESISTANCE of the Air, in *Pneumatics*, is the force with which the motion of bodies, particularly of projectiles, is retarded by the opposition of the air or atmosphere. See GUNNERY.

The air being a fluid, the general laws of the resistance of fluids obtain in it, except that the different degrees of density, in the different stages or regions of the atmosphere, occasion some irregularity.

As to the resistance of the air, it has been thus determined from experiments. Mr. Robins, in his *New Principles of Gunnery*, chap. 2. prop. 2, &c. having taken a musket barrel, and charging it successively with a leaden ball of three-quarters of an inch diameter, and about half its weight of powder, and taking such precaution in weighing of the powder, and placing it, as to be sure, by many previous trials, that the velocity of the ball could not differ by 20 feet in 1" from its medium quantity, fired it against a pendulum, called the ballistic pendulum, (described under GUNNERY), placed at 25 feet, at 75 feet, and at 125 feet distance from the mouth of the piece respectively. In the first case, it impinged against the pendulum with a velocity of 1670 feet in 1"; in the second case, with a velocity of 1550 feet in 1"; and in the third case, with a velocity of 1425 feet in 1"; so that in passing through 50 feet of air, the bullet lost a velocity of about 120 or 125 feet in 1"; and the time of its passing through that space being about  $\frac{1}{37}$  or  $\frac{1}{30}$ th of 1", the medium quantity of resistance must, in these instances, have been about 120 times the weight of the ball; which, as the ball was nearly  $\frac{1}{16}$ th of a pound, amounts to about 10lbs. avoirdupois.

Now, if a computation be made, according to the method laid down for compressed fluids, in the 38th propof. of lib. ii. of sir Isaac Newton's *Principia*, supposing the weight of water to be to the weight of air as 850 to 1, it will be found that the resistance of a globe of three-quarters of an inch diameter, moving with a velocity of about 1600 feet in 1", will not, on those principles, amount to any more than a force of 4 $\frac{1}{2}$ lbs. avoirdupois; whence we may conclude, the rules in that proposition for slow motions being very accurate, that the resisting power of the air in slow motions is less than in swift motions, in the ratio of 4 $\frac{1}{2}$  to 10, a proportion between that of 1 to 2, and 1 to 3.

Again, charging the same piece with equal quantities of powder, and balls of the same weight, and firing three times at the pendulum, placed at 25 feet distance from the mouth of the piece, the medium of the velocities with which the ball impinged was nearly that of 1690 feet in 1". Then removing the piece 75 feet from the pendulum, the velocity of the ball, at a medium of five shots, was that of 1300 feet in 1". Whence the ball, in passing through 150 feet of air, lost a velocity of about 390 feet in 1"; and the resistance, computed from these numbers, gives something more than in the preceding instance, amounting to between 11 and 12 pounds avoirdupois: whence, according to these experiments, the resisting power of the air to swift motions is greater than in slow ones, in a ratio which approaches nearer to the ratio of 3 to 1, than in the preceding experiments. Next, to examine this resistance in smaller velocities, the pendulum being placed at 25 feet distance, was fired at five times, with an equal charge each time, and the mean velocity with which the ball impinged, was that of 1180 feet in 1". Then removing the pendulum to the distance of 250 feet, the medium velocity of five shot, at this distance, was that of 950 feet in 1"; whence the ball, in passing through 225 feet of air, lost a velocity of 230 feet in 1", and as it passed through that interval in about  $\frac{1}{37}$ ths of 1", the resistance to the middle velocity will come out to be near 33 $\frac{1}{2}$  times the gravity of

the ball, or 2lb. 10oz. avoirdupois. Now the resistance to the same velocity, according to the laws observed in slower motions, amounts to  $\frac{1}{7}$ ths of the same quantity; whence, in a velocity of 1065 feet in 1" (the medium of 1180 and 950), the resisting power of the air is augmented in no greater proportion than that of 7 to 11; whereas, in greater degrees of velocity, as before, it amounted very nearly to the ratio of 1 to 3.

By other experiments, it appears, that the resistance of the air is very sensibly increased, even in so small a velocity as that of 400 feet in 1".

That this resisting power of the air to swift motions is very sensibly increased beyond what sir Isaac's theory for slow motions makes it, seems hence to be evident. It being, as has been said, in musket, or cannon shot, with their full charge of powder, nearly three times the quantity assigned by that theory.

However, this increased power of resistance diminishes as the velocity of the resisted body diminishes, till at length, when the motion is sufficiently abated, the actual resistance coincides with that supposed in the theory.

The resistance of a bullet of three-quarters of an inch diameter, moving in air with the velocity of 1670 feet in 1", amounting, as we said, to 10lbs., the resistance of a cannon ball of 24lbs., fired with 16lbs., or its full charge of powder, and thereby moving with a velocity of 1650 feet in 1", (which scarcely differs from the other), may hence be determined. For the velocity of the cannon ball being nearly the same as the musket bullet, and its surface above 54 times greater, it follows that the resistance on the cannon ball will amount to more than 540lbs. which is nearly 23 times its own weight.

Euler has shewn, that the common doctrine of resistance answers very well when the motion is not very swift, but in very swift motions it gives the resistance less than it ought to be, on two accounts. 1. Because in very quick motions the air does not fill up the space behind the body fast enough to press on the hinder parts, that the resistance on the fore part is increased. 2. The density of the air before the ball, being increased by the quick motion, will press more strongly on the fore part, and, being heavier than in its natural state, will retard its motion.

He has also shewn, that Mr. Robins has restrained his rule to velocities not exceeding 1670 feet in 1"; whereas, had he extended it to greater velocities, the result must have been erroneous: as he apprehends that it is not perfectly exact, when the motion is not extremely swift. He has investigated a formula for determining the degree of this resistance, and deduced conclusions differing from those of Mr. Robins. See *Principles of Gunnery* investigated, &c. 1777, p. 224, &c.

Mr. Robins having proved that, in very great changes of velocity, the resistance does not accurately follow the duplicate proportion of the velocity, lays down two positions, which may be of considerable service in the practice of artillery, till a more complete and accurate theory of resistance, and the changes of its augmentation, may be obtained. The first of these is, that till the velocity of the projectile surpasses that of 1100 feet in a second, the resistance may be esteemed to be in the duplicate proportion of the velocity: and the second is, that if the velocity be greater than that of 1100 or 1200 feet in a second, the absolute quantity of the resistance will be nearly three times as great as it should be by a comparison with the smaller velocities. Upon these principles, he proceeds in approximating the actual ranges of pieces with small angles of elevation, *viz.* such as do not exceed 8° or 10°, which he sets down in a table, compared with their corresponding potential ranges. See his *Mathematical Tracts*, vol. i. p. 179, &c.

# RESISTANCE.

Since the above experiments of Mr. Robins, Dr. Hutton has profecuted the subject to a much greater length. His experiments were made not only with the whirling machine invented by the former, but with cannon balls of different weights, from 1lb. to 6lbs. ; as also with figures of various shapes, and with planes set at a variety of angles of inclina-

tions to the path of motion. From these experiments the author has ascertained the refistance of bodies to all velocities, from 1 to 2000 feet *per* second ; the bodies being different, and their faces at different angles of elevation. Some of his general tables, and conclusions from those experiments, are as follows.

TABLE I. Of Resistances of different Bodies.

In this table are contained the resistances of several forms of bodies, when moved with several degrees of velocity, from 3 feet *per* second to 20 feet *per* second. The names of the bodies are at the tops of the columns, as also which end went foremost through the air ; the different velocities are in the first column, and the resistance, on the same line in their several columns in avoirdupois ounces and decimal parts. Thus, on the first line are contained the resistances when the bodies move with a velocity of three feet in a second ; *viz.* in the second column, for the small hemisphere of  $4\frac{3}{4}$  inches diameter, its resistance .028 ounces, when the flat side went foremost ; in the third and fourth columns, the resistances to a large hemisphere, first with the flat side, and next with the convex part foremost ; the diameter of this, as well as all the following figures, being  $6\frac{5}{8}$  inches, and therefore the area of the great circle = 32 square inches, or  $\frac{2}{3}$  of a square foot ; then in the fifth and sixth columns are the resistances of a cone, first, with its vertex, and then with its base foremost ; the altitude of the cone being  $6\frac{5}{8}$  inches, the same as the diameter of its base ; in the seventh column, the resistance to the end of the cylinder ; and in the eighth, that against the whole globe or sphere. All the numbers shew the real weights which are equal to the resistances ; and at the bottoms of the columns are placed proportional numbers, which shew the mean proportions of the resistances of all the figures to each other with any velocity. Lastly, in the ninth column are placed the exponents of the power of the velocity which the resistances in the eighth column bear

to each other, *viz.* which that of the 10 feet velocity bears to each of the following ones ; the medium of all them being as the 2.04 power of the velocity ; that is, very little above the square, or second power, so far as the velocities in this table extends.

From this table the following inferences are readily deduced.

1. That the resistance is nearly in the same proportion as the surfaces ; a small increase only taking place in the greatest surfaces, and for the greater velocities : thus, by comparing together the numbers in the second and third columns for the bases of the two hemispheres, the areas of which bases are in the proportion of  $17\frac{3}{4}$  to 32, or 5 to 9 very nearly, it appears that the numbers in these two columns, expressing the resistances, are nearly as 1 to 2, or 5 to 10, as far as the velocity of 12 feet : but after that, the resistances on the greater surface increase gradually more and more above that proportion.

2. The resistance to the same surface, with different velocities, is, in these slow motions, nearly as the square of the velocity ; but gradually increases more and more above that proportion, as the velocity increases. This is manifest from all the columns ; and from the index of the power of the velocity set down in the ninth column for the resistances in the eighth, the medium of which being 2.04, shews that the resistance to the same body is, in these slow motions, as the 2.04 power of the velocity, or nearly as the square of it.

3. The round ends, and the sharp ends, of solids, suffer less

# RESISTANCE.

less resistance than the flat or plane ends of the same diameter; but the sharper end has not always the least resistance. Thus, the cylinder, and the flat ends of the hemisphere, and cone, have more resistance than the round or sharp ends of the same, but the round side of the hemisphere has less resistance than the sharp end of the cone.

4. The resistance on the base of the hemisphere is to that of its convex part, as  $2\frac{1}{2}$  to 1, instead of 2 to 1, as given by theory. The experimented resistances also exceed the theoretical by nearly  $\frac{1}{4}$ th.

5. The resistance on the base of the cone is to that on its vertex, nearly as  $2\frac{1}{2}$  to 1, which is the same as the ratio of the sine of the angle of inclination of the side of the cone to its axis; so that, in this instance, the resistance is as the sine of the angle of incidence.

6. When the hinder parts of different bodies are of different forms, the resistances are different, although the fore parts be exactly the same; owing probably to the different pressures of the air on the hinder parts.

Thus the resistance to the fore-part of the cylinder is less than on the equal flat surface of the cone, or of the hemisphere; and the resistance on the base of the hemisphere less than that of the cone; and the round side of the hemisphere less than the whole sphere.

TABLE II. Resistance, both by Experiment and Theory, to a Globe of 1.965 Diameter.

In the first column of this table are contained the several velocities, gradually, from 5 feet per second to the greatest velocity of 2000 feet per second, with which a globe or ball is moved. In the second column are the experimented

resistances in avoirdupois ounces. In the third, the corresponding resistances as deduced from theory. In the fourth column the ratio of these two resistances, or the quotients of the former divided by the latter; and the fifth, or last, the indices of the power of the velocity which is proportional to the experimented resistances, and which are found by comparing the resistance of 20 feet velocity with each of the following ones.

The following tables are of a similar kind, but the experiments are repeated on balls of different sizes.

TABLE III.—Resistances to a ball of 1.965 inch diameter, and 16 oz. 13 dr. weight.

Velocity. feet.	Resistances.		1st Dif.	2d Dif.

## RESISTANCE.

The analogy among the numbers in all these tables is very remarkable and uniform, the same general law obtaining in them all, by means of which, together with our preceding remarks, we may answer many interesting questions relating to this subject, as connected with artillery practice. For example, suppose it were required to determine what would be the resistance of the air against a 24lb. ball, discharged with a velocity of 2000 feet *per* second. By Table III. the ball of 1.965 inch diameter, when moving with 2000 feet velocity, suffered a resistance of 98lbs.; then since the resistances, with the same velocity, are as the surfaces, and the surfaces as the squares of the diameters; also the diameter of a 24-pound ball being 5.6 inches, we have as  $(1.965)^2 : (5.6)^2$ , or as  $3.86 : 31.36 :: 98\text{lbs.} : 796\text{lbs.}$ , the resistance which a 24lb. ball experiences when discharged with the above velocity. And generally, if the diameter of any proposed ball be  $d$  inches, and  $r$  the tabular resistance corresponding to any velocity  $v$ ; then we shall generally

have as  $(1.965)^2 : d^2 :: r : \frac{r d^2}{(1.965)^2} = \frac{r d^2}{3.8}$ , or very nearly  $\frac{1}{3} r d^2$ .

These resistances relating to certain and determinate velocities, a principal object of investigation has been, amongst experimentalists, to determine some rule or formula by which the resistance may be found for any velocity whatever, and the result of Dr. Hutton's investigations on this subject is as follows, *viz.*

Resistance =  $r = .00002576 v^2 - .00388 v$ , in avoirdupois pounds, the velocity being  $v$ .

This rule  $.00002576 v^2 - .00388 v = r$  denotes the resistance for a ball whose diameter is 1.965 inch, the square of which is 3.9 or 4 nearly. Hence to adapt it to any other ball, whose diameter in inches is  $d$ , we shall have, by the same

proportion as above,  $\frac{d^2}{3.8} (.00002576 v^2 - .00388 v) = (.00000667 v^2 - .0010) d^2 = (.00000 \frac{2}{3} v^2 - .001 v) d^2$ ; for the resistance of any ball whose diameter is  $d$ , and velocity  $v$ .

In smaller velocities the same author finds the theorem  $.00001725 v^2 = r$  sufficiently correct, and this is adapted to a ball whose diameter is  $d$  in exactly the same manner, giving the result  $.00000447 d^2 v^2 = r$  for the resistance when the velocities are small.

For the application of these theorems to the solution of certain problems connected with the doctrine of *projectiles*, see that article: and for various other formulae and results equally curious and interesting, see Dr. Hutton's *Traacts*, as also vol. iii. of his *Course of Mathematics*; *Robins' Gunnery*; *Moore's Theory of Rockets*; *Gregory's Mechanics*; and *Prony's Architecture Hydraulique*.

**RESISTANCE, Different, of the same Medium to Bodies of different Figures.**—Sir Isaac Newton shews, that if a globe and a cylinder, of equal diameters, be moved with equal velocity in a thin medium, consisting of equal particles, disposed at equal distances, according to the direction of the axis of the cylinder; the resistance of the globe will be less by half than that of the cylinder.

**RESISTANCE, Solid of the least.**—From the last proposition the same author deduces the figure of a solid which shall have the least resistance of any containing the same quantity of matter and surface.

The figure is this. Suppose  $D N F G$  (*Plate XXXVI. Mechanics, fig. 15.*) to be such a curve, as that if from any point  $N$  be let fall a perpendicular  $N M$  to the axis  $A B$ ; and from a given point  $G$  be drawn a right line  $G R$  pa-

ral to a tangent to the figure in  $N$ , and cut the axis, when continued, in  $R$ ;  $M N$  be to  $G R$  as  $G R$  *cube*. to  $4 B R \times G B q$ ; a solid described by the revolution of this figure about its axis  $A B$ , moving in a medium from  $A$  towards  $B$ , is less resisted than any other circular solid of the same area, &c.

This theorem, which Sir Isaac Newton has given without a demonstration, has been demonstrated by several mathematicians, as Fatio, Craig, M. d'Hospital, Bernoulli, &c. (See Dr. Horsley's edition of Newton, vol. ii. p. 390, and Maclaurin's *Fluxions*, sect. 606 and 607.) For a more particular investigation of this solid, see prob. 6. under the article **ISOPERIMETRY**.

**RESISTANCE of a Globe** perfectly hard, and in a medium whose particles are so too, is to the force with which the whole motion may either be destroyed, or generated, which it has at the time when it has described four-thirds of its diameter, as the density of the medium to the density of the globe. Hence, also, Sir Isaac Newton infers, that the resistance of a globe is, *ceteris paribus*, in a duplicate ratio of its velocity. Or its resistance is, *ceteris paribus*, in a duplicate ratio of its diameter; or, *ceteris paribus*, as the density of the medium. Lastly, that the actual resistance of a globe is in a ratio compounded of the duplicate ratio of the velocity, and of the duplicate ratio of the diameter, and of the ratio of the density of the medium.

In these articles the medium is supposed to be discontinuous, as air probably is: if the medium be continuous, as water, mercury, &c. where the globe does not strike immediately on all the particles of the fluid generating the resistance, but only on those next it, and those again on others, &c. the resistance will be less by half: and a globe in such a medium undergoes a resistance which is to the force with which the whole motion it has after describing eight-thirds of its diameter, might be generated, or taken away, as the density of the medium to the density of the globe.

**RESISTANCE of a Cylinder**, moving in the direction of its axis, is not altered by any augmentation or diminution of its length; and therefore is the same with that of a circle of the same diameter, moving with the same velocity in a right line perpendicular to its plane.

The resistance of a cylinder, moving in an infinite non-elastic fluid, arising from the magnitude of a transverse section, is to the force with which its whole motion, while it describes four times its length, may be taken away, or generated, as the density of the medium to that of the cylinder, very nearly.

Hence, the resistance of cylinders moving lengthwise, in infinitely continued mediums, are in a ratio compounded of the duplicate ratio of their diameters, the duplicate ratio of their velocities, and ratio of the density of mediums.

The resistance of a globe, in an infinite non-elastic medium, is to the force by which its whole motion, while it describes eight-thirds of its diameter, might be either generated or taken away, as the density of the fluid to the density of the globe, *quam proxime*.

**RESISTANCE of Matter.** (See **MATTER**.) The meaning of this expression is not, that matter makes any opposition to a change of its state, or exerts a force to maintain itself in the state it is, as some have very improperly expressed themselves. This would imply that activity which is inconsistent with its nature; and if it were true, a part of the force of every impulse would be spent merely in overcoming this opposition, without producing any other effect; and, therefore, the sum of the motions the same way would always be greater before than after collision, which is impossible. The *largest* body will be moved by any the

*lightest*

*lightest* impulse of the *smallest*; but then it can be moved only in proportion to the force of the impulse, and this is what is chiefly meant by the *resistance* of matter: *e. gr.* a body at rest will *resist* another which is moving towards it; that is, it will be an *obstruction* to the motion of this other; the latter will be retarded by the former, and will lose just as much motion as it communicates. In other words; the resistance of matter is that in its nature which makes it require an *adequate foreign cause* of every change of state, or from whence it is *wholly passive*, and incapable of receiving any motion from impulse, that is not in a certain fixed proportion to the *relative momentum* of the impelling body, and strictly equal to the change of state it suffers in consequence of the impulse. In this proportion matter is always moved *without difficulty*; but beyond this there is not only a *difficulty*, but an *impossibility* of moving it; and whatever motion it can be supposed to receive from any impulse that is greater than that which the impelling body loses, it must derive from nothing at all. The activity which is denied to matter, is a power of changing its own state, not that of acting upon other matter by *impulse*. This sort of activity, or power, follows from, and is necessarily implied in its perfect passiveness or inertia. See Price's Dissertations, p. 35, note.

*Non-RESISTANCE*, in *Politics*. See *PASSIVE Obedience*.

*RESITU*, in *Geography*, a town of Naples, in the province of Capitanata; 16 miles N.N.W. of Vieste.

*RESLEU*, a river which rises in Bavaria, and runs into the Egra, in Bohemia.

*RESOLIF*, a town of Scotland, in the county of Cromarty; 7 miles W. of Cromarty.

*RESOLVENTS*, *RESOLVENTIA*, in the *Materia Medica*, remedies proper to resolve and dissipate tumours and gatherings, to soften indurations, and, by their tenuity and warmth, evacuate redundant or peccant humours through the pores.

Under this class come various unguents, emplaisters, &c.

*RESOLUTION*, *RESOLUTIO*, or *Solutio*, in *Physics*, the reduction of a body into its original or natural state, by a dissolution or the separation of its aggregated parts.

Thus snow and ice are said to be resolved into water; and a compound is resolved into its ingredients, &c.: water resolves into vapour by heat; and vapour is again resolved into water by cold.

Some of the modern philosophers, particularly Mr. Boyle, M. Mariotte, Boerhaave, &c. maintain that the natural state of water is to be congealed, or in ice; inasmuch as a certain degree of heat, which is a foreign and violent agent, is required to make it fluid: so that near the pole, where this foreign force is wanting, it constantly retains its fixed or icy state. On this principle, the resolution of ice into water must be allowed an improper expression.

*RESOLUTION*, in *Chemistry*, is the reduction of a mass, or mixed body, into its component parts, or first principles, by proper analysis.

The resolution of bodies is performed variously; by distillation, sublimation, dissolution, fermentation, &c. See each operation under its proper article. See also *DISSOLUTION* and *SOLUTION*.

*RESOLUTION*, in *Ethics*, is that passion which encounters difficulties and dangers; but when it has to do more peculiarly with dangers, it is called boldness. Desire, joy, and sorrow, enter into its constitution; but joy is much the principal ingredient. When resolution degenerates into a concern to maintain our mistakes, humours, or vices, it is more properly denominated obstinacy. See *PASSIONS*.

*RESOLUTION*, in *Logic*, is a branch of *method*, called also *analysis*,

The business of resolution is to investigate or examine the truth or falsehood of a proposition, by ascending from some particular known truth, as a principle, by a chain of consequences, to another more general one in question. Resolution, or the analytic method, stands in direct opposition to *composition*, or the synthetic method; in which last we descend from some general known truths to a particular one in question.

For an instance of the method of resolution; suppose the question this: Whether, on the supposition of man's existence, we can prove that God exists?

To resolve this, our method is thus: Mankind did not always exist. It is evident, from a thousand considerations, the species had a beginning; and that, according to all history, not six thousand years ago; but if it had a beginning, there must be some cause of its beginning; something to induce it to exist then more than it did before; in effect, there must be a cause or author of its existence; for from nothing, nothing arises: this cause, whatever it is, must, at least, have all the faculties we find in ourselves; for none can give more than he has: nay, he must have others, which we have not, since he could do what we cannot do, *i. e.* create, make man exist, &c. Now, this cause either exists still, or has ceased to do so: if the former, he did not exist from eternity; for what is from eternity is necessary, and can neither by itself, nor any other cause, be reduced to nothing: if the latter, it must have been produced from some other; and then the same question will return upon the producer. There is then some first cause, and this cause has all the properties and faculties we have; nay more, has existed from eternity, &c. Therefore, from the supposition of man's existence, it follows that there is a God.

*RESOLUTION*, or *Solution*, in *Mathematics*, is an orderly enumeration of several things to be done, to obtain what is required in a problem.

Wolfius makes a problem to consist of three parts. The *proposition* (which is what we properly call the *problem*), the *resolution*, and the *demonstration*.

The general tenor of all problems is, those things being done which are enjoined by the resolution, the thing is done which was to be done.

As soon as a problem is demonstrated, it is converted into a theorem; of which the resolution is the hypothesis; and the proposition the thesis.

The process of a mathematical resolution, see in the following article.

*RESOLUTION*, in *Algebra*, or *algebraical*, is of two kinds; the one practised in numerical problems, the other in geometrical ones.

*RESOLUTION of Equations*, is the determination of the values of the unknown letters or quantities of which it is composed; in order to which it is necessary, first, to exterminate or eliminate all the unknown quantities but one out of the equation, and then the value of the remaining quantity is to be found by the proper rules for this purpose, *viz.* by the rules given for *simple, quadratic, cubic, or biquadratic equations*, according to which of these it may belong; or, by the general method of *approximation*, for which see the respective articles. But as all these cases have reference only to one unknown quantity, it will not be amiss, in this place, to explain some of those methods which are most commonly employed for reducing equations to one unknown.

First, it may be observed, that in any determinate problem there are always as many equations independent of each other, as there are unknown quantities; if there are not so many, the question is *indeterminate*, and if there be more, it is *impossible*.

# RESOLUTION OF EQUATIONS.

We cannot, in a limited article like the present, give all the methods that may be employed for exterminating the unknown letters; these being extremely various, and depending much upon the practice and proficiency of the analyst himself, and the manner in which those quantities are involved; but the most applicable and general methods are the three following, *viz.*

1. Find the value of one and the same unknown quantity in each equation, and put all these values equal to each other, which will eliminate one of the quantities, and reduce the number of equations to one less. Then do the same in these new equations; and again in the last; and so on, till there be but one equation and one unknown quantity, the value of which must be found by the proper rules, as above referred to.

2. Find the value of one of the unknown quantities in one of the equations, in terms of the other quantities; then substitute this value for that quantity in all the other equations; again, find the value of one of the remaining quantities, and substitute its value as before; and so on, till there remains but one equation and one unknown quantity, whose value is to be found as before.

3. Multiply each of the equations by such numbers as will render the co-efficients of one of the letters the same in all; then, by adding or subtracting these equations according as the equal co-efficients have unlike or like signs, the quantity whose co-efficients were equal will disappear; which being repeated again upon the remaining quantities, there will ultimately be found only one equation and one unknown quantity. And it may be proper to observe, that in all these cases, if any of the unknown quantities have fractional co-efficients, the whole equation in which they are found should be multiplied by such a number as will convert these fractions into integers.

Thus, in the equations

$$\begin{aligned} \frac{1}{5}x + \frac{2}{15}y &= 10 \\ \frac{1}{3}x + 3y &= 95 \end{aligned}$$

multiply the first by 15, and the latter by 2, gives

$$\begin{aligned} 9x + 2y &= 150 \\ x + 6y &= 190 \end{aligned}$$

the solution of which, by each of the preceding rules, will be as follows.

Or, putting letters instead of the above numerical co-efficients, in order to render the solution more general, let there be given

$$\begin{aligned} ax + by &= c \\ dx + ey &= f \end{aligned} \text{ to find } x \text{ and } y.$$

1st method.  $\left. \begin{aligned} ax &= c - by \\ dx &= f - ey \end{aligned} \right\}$  by transposition.

$$x = \frac{c - by}{a} = \frac{f - ey}{d} \text{ by division.}$$

$dc - dby = af - aey$ , by multiplication.

$$(ae - db)y = af - dc$$

$$y = \frac{af - dc}{ae - db}$$

And in the same manner we find,

$$x = \frac{ec - bf}{ae - db}$$

2d method.  $\left. \begin{aligned} ax + by &= c \\ dx + ey &= f \end{aligned} \right\}$  to find  $x$  and  $y$ .

$$x = \frac{c - by}{a} \text{ as above.}$$

$$\frac{dc - dby}{a} + ey = f, \text{ by substit.}$$

$dc - dby + aey = af$ , by multiplication.

$$(ae - db)y = af - dc$$

$$y = \frac{af - dc}{ae - db} \text{ as before.}$$

$$x = \frac{ec - bf}{ae - db}$$

3d method.  $\left. \begin{aligned} ax + by &= c \\ dx + ey &= f \end{aligned} \right\}$  to find  $x$  and  $y$ .

$dax + dby = dc$ , mult. by  $d$ .

$adx + acy = af$ , mult. by  $a$ .

$$(db - ac)y = dc - af$$

$$\left. \begin{aligned} y &= \frac{dc - af}{db - ac} = \frac{af - dc}{ae - db} \\ x &= \frac{bf - ec}{db - ae} = \frac{ec - bf}{ae - db} \end{aligned} \right\} \text{ as before.}$$

This will, in some measure, illustrate the preceding rules, which we shall not insist upon any further; but, in the following examples, shall avail ourselves of any advantages that the equations present, in order to arrive at the solution in the easiest manner possible.

*Examples.*

1. Given  $\left. \begin{aligned} x^2 + y^2 &= a \\ xy &= b \end{aligned} \right\}$  to find  $x$  and  $y$ .

$$\begin{aligned} x^2 + y^2 &= a \\ 2xy &= 2b, \text{ doubling the 2d.} \end{aligned}$$

$x^2 + 2xy + y^2 = a + 2b$ , by addition.

$x^2 - 2xy + y^2 = a - 2b$ , by subtraction.

$x + y = \sqrt{a + 2b}$  } by extraction.

$$x - y = \sqrt{a - 2b}$$

$$x = \frac{\sqrt{a + 2b} + \sqrt{a - 2b}}{2}$$

$$y = \frac{\sqrt{a + 2b} - \sqrt{a - 2b}}{2}$$

2. Given  $\left. \begin{aligned} x + y &= a \\ xy &= b \end{aligned} \right\}$  to find  $x$  and  $y$ .

$x^2 + 2xy + y^2 = a^2$ , by squaring.

$4xy = 4b$ , mult. by 4.

$x^2 - 2xy + y^2 = a^2 - 4b$ , by subtraction.

$x - y = \sqrt{a^2 - 4b}$ , by extraction.

$x + y = a$ , 1st equation.

$$x = \frac{a + \sqrt{a^2 - 4b}}{2}$$

$$y = \frac{a - \sqrt{a^2 - 4b}}{2}$$

3. Given  $\left. \begin{aligned} x - y &= a \\ xy &= b \end{aligned} \right\}$  to find  $x$  and  $y$ .

$x^2 - 2xy + y^2 = a^2$ , squaring.

$4xy = 4b$ , mult. by 4.

$x^2 + 2xy + y^2 = a^2 + 4b$ , by addition.

$x + y = \sqrt{a^2 + 4b}$ , by extraction.

$x - y = a$

$$x = \frac{a + \sqrt{a^2 + 4b}}{2}$$

$$y = \frac{a - \sqrt{a^2 + 4b}}{2}$$

4. Given

4. Given  $x - y = a$   
 $x^2 + y^2 = b$  } to find  $x$  and  $y$ .  
 $x^2 - 2xy + y^2 = a^2$ , squaring.  
 $2x^2 + 2y^2 = 2b$ , doubling.  
 $x^2 + 2xy + y^2 = 2b - a^2$ , subtr.  
 $x + y = \sqrt{2b - a^2}$   
 $x - y = a$

$$x = \frac{a + \sqrt{2b - a^2}}{2}$$

$$y = \frac{a - \sqrt{2b - a^2}}{2}$$

This method of resolution will apply in many problems, and sometimes saves considerable labour.

5. Given  $x^2 + xy = a$   
 $y^2 + xy = b$  } to find  $x$  and  $y$ .  
 $x^2 + 2xy + y^2 = a + b$ , by adding.  
 $x + y = \sqrt{a + b}$ , by extract.  
 $(x + y)x = x\sqrt{a + b} = a$   
 $(x + y)y = y\sqrt{a + b} = b$

$$x = \frac{a}{\sqrt{a + b}}, \text{ and } y = \frac{b}{\sqrt{a + b}}$$

6. Find three numbers in arithmetical progression, whose sum is  $a$ , and sum of their squares  $b$ .

Let  $x - y$ ,  $x$  and  $x + y$ , be the numbers required.

Then  $x - y + x + x + y = 3x = a$   
 $(x - y)^2 + x^2 + (x + y)^2 = 3x^2 + 2y^2 = b$

$$x^2 = \frac{a^2}{9} = \frac{b - 2y^2}{3}$$

Whence  $a^2 = 3b - 6y^2$

and  $y = \sqrt{\frac{3b - a^2}{6}}$ , and  $x = \frac{a}{3}$ .

And a similar substitution, viz. one which answers one of the conditions of the question, may frequently be employed to great advantage.

7. Sometimes it will be convenient to substitute for the sums and differences of numbers, as in the following example.

Given  $x + y = a$   
 $x^3 + y^3 = b$  } to find  $x$  and  $y$ .

Let  $x + y = 2m$   
 and  $x - y = 2n$  } then  $\begin{cases} x = m + n \\ y = m - n \end{cases}$

$$(m + n)^3 + (m - n)^3 = b,$$

$$\text{or } 2m^3 + 12m^2n^2 + 2n^3 = b;$$

but  $2m = a$ , or  $m = \frac{a}{2}$ ; therefore  $m$  is known, and the above becomes

$$2n^3 + 12m^2n^2 = b - 2m^3$$

$$n^3 + 6m^2n^2 = \frac{1}{2}b - m^3$$

$$n^2 = -3m^2 \pm \sqrt{\left(\frac{1}{2}b + 8m^3\right)}$$

$$\text{and } n = \left[3m^2 \pm \sqrt{\left(\frac{1}{2}b + 8m^3\right)}\right]^{\frac{1}{2}}.$$

Whence  $m$  and  $n$  being known,  $x$  and  $y$  are also known; for  $x = m + n$ , and  $y = m - n$ .

8. Sometimes it is advantageous to consider one of the quantities as an unknown multiple of the other; thus:

Given  $xy = x^2 - y^2 = x^3 + y^3$ , to find  $x$  and  $y$ .

Make  $y = zx$ , then these become

$$zx^2 = x^2 - z^2x^2$$

$$zx^2 = x^3 + z^3x^3$$

$$z = 1 - z^2, \text{ from the first,}$$

$$z^2 + z = 1, \text{ or } z = -\frac{1}{2} + \frac{1}{2}\sqrt{5};$$

whence  $z$  is a known quantity. Now,

$$z = x + z^3x, \text{ from the second,}$$

$$x = \begin{cases} \frac{z}{1 + z^3} = \frac{-\frac{1}{2} + \frac{1}{2}\sqrt{5}}{1 - (\frac{1}{2} - \frac{1}{2}\sqrt{5})^3} \\ \frac{-\frac{1}{2} + \frac{1}{2}\sqrt{5}}{-1 + \sqrt{5}} = \frac{1}{2} \end{cases}$$

$$y = zx = -\frac{1}{4} + \frac{1}{4}\sqrt{5}, \text{ as required.}$$

Sometimes it saves considerable labour, to find the sum, product, or difference, of the two quantities, instead of the quantities themselves; thus:

9. Given  $x^2 + y^2 - x - y = a$   
 $xy + x + y = b$ ;

by addition  $x^2 + xy + y^2 = a + b$   
 $x^2 + 2xy + y^2 = a + b + xy$   
 $x + y = \sqrt{a + b + xy}$ ;

but  $x + y = b - xy$ ;

therefore  $b^2 - 2bxy + x^2y^2 = a + b + xy$   
 $x^2y^2 - (2b + 1)xy = a + b - b^2$ ;

whence  $xy = \frac{2b + 1}{2} \pm \sqrt{\left(\frac{2b + 1}{2}\right)^2 + a + b - b^2}$ .

Now make  $xy = p$  a known quantity, and we have, from the second equation,

$$\begin{aligned} p + x + y &= b, \\ \text{or } x + y &= b - p \\ xy &= p \end{aligned}$$

whence  $x^2 - 2xy + y^2 = (b - p)^2 - 4p$   
 $x - y = \sqrt{[(b - p)^2 - 4p]}$   
 $x + y = b - p$

therefore  $x = \frac{b - p + \sqrt{[(b - p)^2 - 4p]}}{2}$

$$y = \frac{b - p - \sqrt{[(b - p)^2 - 4p]}}{2}$$

These, and a variety of other artifices peculiar to certain equations, will occur to the practical analyst; of which, numerous examples may be seen in Bland's Algebraical Problems, as also in Bonnycastle's and Euler's Algebra.

RESOLUTION of a geometrical Problem algebraically. The process in the former article is to be observed throughout; but as it rarely happens we come at an equation in geometrical problems by the same means as in numerical ones, there are some farther things to be noted: 1st, then, suppose the thing done, which was proposed to be done. 2. Examine the relations of all the lines in the diagram, without any regard to known or unknown, in order to find which depends on which; and from which being had, what others are had, whether by similar triangles, or rectangles, &c. 3. To obtain the similar triangles or rectangles, the lines are to be frequently produced, till they become either directly or indirectly equal to given ones, or intersect others, &c. Parallels and perpendiculars to be frequently drawn; points to be frequently connected; and angles to be made equal to others. If thus you do not arrive at a neat equation, examine the relation of the lines in another manner.

Sometimes it is not enough to seek the thing directly, but another thing must be sought, whence the first may be found.

The equation being reduced, the geometrical construction is to be deduced from it, which is done in various manners, in the various kinds of equations. See *APPLICATION of Algebra to Geometry*.

**RESOLUTION, Problematical.** See **PROBLEMATICAL**.

**RESOLUTION, in Medicine,** the termination of an inflammation, without any change in the texture of the part inflamed, in contradistinction to the termination in suppuration or gangrene. The great object of medicine, in all inflammatory diseases, in the commencement, is to obtain the resolution of the inflammation, so that the structure and functions of the part affected may not be injured by the disease: and the means of obtaining a resolution, when the inflammation is seated in an internal part, are evacuations of blood by the lancet, cupping, or leeches; and of serum, by purging the bowels, applying blisters in the vicinity, &c.; and when the inflammation is external, by local evacuations by similar means, and by the application of cold substances. See **INFLAMMATION**.

**RESOLUTION, in Music,** is when a canon or perpetual fugue is not written all on the same line, or in one part; but all the voices that are to follow the guida, or first voice, are written separately, either in score, *i. e.* in separate lines, or separate parts, with the pauses each is to observe, in the beginning, and in the tone proper to each.

The resolution of discords, in music, is generally by their descent upon concords; except the *tritonus*, or sharp 4th, and the *note sensible*, or sharp 7th of a key, which ascend, while the base descends or remains stationary.

**RESOLUTION, in Surgery,** the most favourable manner in which the process of inflammation can terminate, consisting of a gradual abatement of the pain, redness, swelling, throbbing, and heat of the part, without any formation of matter, and without any sloughing. Also, the dispersion of swellings and indurations, through the medium of absorption.

**RESOLUTION of Motion, in Mechanics.** See **MOTION**.

**RESOLUTION Bay, in Geography,** a name given by captain Cook to the port of Madre de Dios, situated near the middle of the W. side of St. Christina, one of the Marquesas islands, in the South Pacific ocean, and under the highest land in the island, in S. lat.  $9^{\circ} 55' 30''$ , W. long.  $139^{\circ} 8' 40''$ , and N.  $15^{\circ}$  W. from the W. end of La Dominica. The south point of the bay is a steep rock of considerable height, terminating at the top in a peaked hill, above which may be seen a path-way leading up a narrow ridge to the summit of the hills. The north point is not so high, and rises with a more gentle slope. They are a mile from each other in the direction of N. by E., and S. by W. In the bay, which is near three quarters of a mile deep, and has from 34 to 12 fathoms water, with a clean sandy bottom, are two sandy coves, divided from each other by a rocky point. In each is a rivulet of excellent water. The northern cove is the most commodious for wooding and watering. Here is the little water-fall mentioned by Quiros, Mendana's pilot; but the town, or village, is in the other cove. There are several other coves or bays on this side of the island; and some of them, especially to the northward, may be mistaken for this: therefore the best direction is the bearing of the west end of La Dominica. Cook's Voyage, vol. i. p. 307.

**RESOLUTION Island,** one of the newly-discovered Society islands, in the South Pacific ocean. S. lat.  $17^{\circ} 24'$ . W. long.  $141^{\circ} 15'$ .—Also, an island in the North Atlantic ocean, 60 miles in circumference, situated on the N. side of

the entrance into Hudson's straits. N. lat.  $61^{\circ} 40'$ . W. long.  $65^{\circ}$ .

**RESOLUTION Port,** a bay or harbour of the island of Tanna, in the South Pacific ocean. S. lat.  $19^{\circ} 32'$ . E. long.  $169^{\circ} 40'$ .

**RESONANCE, in Music,** is sounding again, repeating or continuing the sound. The resonance of a string, a bell, or other sonorous body, ceases with the vibration.

It expresses the sound returned by the air inclosed in the bodies of stringed musical instruments, as lutes, &c.; or even in the bodies of wind instruments, as flutes, &c.

Elliptic and parabolic vaults resound strongly, *i. e.* they strongly reflect or return the sound. See **ECHO**.

The mouth, and the parts thereof, as the palate, tongue, teeth, nose, and lips, Monf. Dodart observes, contribute nothing to the tone of the voice; but their effect is very great as to the resonance.

Of this we have a very sensible instance in that vulgar instrument called *Jews-harp*, or *trompe de Bearn*: for if you hold it in your hand, and strike the tongue or spring thereof, which yields all the sound of the instrument, it scarcely makes any noise at all; but, holding the body of the instrument between the teeth, and striking the spring as before, it makes a musical buzz, which is heard to a good distance, and especially in the lower notes.

So also in the hautboys, the tone of the reed is always the same; being a sort of drone: the chief variety is in the tone of the resonance, produced in the mouth by the greater or less aperture, and the divers motions of the lips.

**RESORT.** See **RESSORT**.

**RESOUZE, in Geography,** a river of France, which runs into the Saone, near Pont de Vaux, in the department of the Ain.

**RESP,** a disease in sheep, the same as red-water. See **RED-WATER**.

**RESPECT, in Ethics,** denotes that favourable impression which the goodness of a character has made upon the person contemplating it, united with a share of good sense. An union of both these qualities is necessary to create respect. Goodness alone is not sufficient to produce it; for if it be seated in a mind that indicates extreme imbecility, it cannot be deemed respectable. On the other hand, superior sense in a mind destitute of goodness, will not inspire respect: it will either waste itself in idle speculations, which renders it indifferent to us; or it may degenerate into low cunning, which renders it hateful. Should it be connected with power in a wicked and perverse mind, it will excite horror and dismay, which are very remote from respect.

**RESPECTU computi vicecomitis habendo, in Law,** a writ for the respiting of a sheriff's account, upon just occasion, directed to the treasurer and barons of the exchequer.

**RESPECTUANDO HOMAGIO.** See **HOMAGIO**.

**RESPIRATION, in Physiology,** that function of animal bodies, in which the air, either in its elastic state, as it constitutes the atmosphere, or held in solution in water, is brought into contact with some organ or organs, undergoing alterations in its own constitution, and producing changes in the nature of the animal fluids, which are essential to the continuance of life. In the mammalia, birds, and reptiles, the respiratory organs consist of lungs, that is, of membranous cavities, differently constructed in the three classes, but agreeing in the circumstance of alternately receiving and emitting a portion of atmospheric air. This alternate ingress and egress of air constitutes properly what is called in common language *breathing*, to which the philosophical term *respiration* is synonymous. We extend the term to animals of the lower classes, which have no lungs, and some

## RESPIRATION.

of which do not even *breathe*, that is, do not receive and emit air at all. In consequence of the medium in which fishes are immersed, they cannot take in the atmospheric air in its elastic state, and they consequently have an apparatus, altogether different from that which exists in the three classes already named, for the purpose of producing analogous effects in their economy. They are furnished with a passage communicating with the fauces or œsophagus, and terminating in the external surface of the body, through which a part of the water received into the mouth is forcibly propelled. In this passage, the branchiæ or gills are situated; and the blood, which circulates in their fringed extremities, is thus exposed to the action of a quantity of air, which the water always holds in solution. Crustaceous animals, and many of the mollusca, have organs more or less similar in structure and functions to the gills of fishes. Insects, both in their larva and perfect states, possess numerous ramified tubes, distributed over their whole body, and provided with open mouths, which admit the passage to and fro of the external air. Although the structure of the organs in fishes and insects is so different from that which we find in mammalia, birds, and reptiles, they perform an analogous office, answer the same general purposes in the animal economy, and are considered equally in the light of organs of *respiration*; this term being employed now to denote the general effect produced by these various organizations, without any reference to the means through which it is produced; although it was originally applied to the passage of the air to and from the lungs, when the results of that process were unknown.

Is respiration, considered in its most extensive sense, a function necessary to the existence of all animals? The results of all the investigations hitherto made, induce us to answer this question in the affirmative; but the point is not yet demonstrated in all cases.

In Cuvier's class of zoophytes, excepting the echinodermata, no respiratory apparatus has been found; nor has any been yet discovered in the intestinal worms, or in some of the external worms, as the leech, earth-worm, and others. It may be doubted, since the analogy on which we ground our opinion of the necessity of air to animal existence is so very strong, whether the apparent exception afforded by the animals just enumerated may not arise from our imperfect knowledge of their organization, and whether more accurate inquiries may not either disclose to us in these cases some particular organ of respiration, or shew us that the function is performed by the external surface of the body in general. We know, in fact, by direct experiment, that some of these animals produce changes in the air, and cannot live when debarred from its access.

The differences which animals exhibit in their mode of breathing, or in the manner of effecting the changes which their nutritive fluid undergoes from the action of the atmosphere, depend on other circumstances in their organization. Vegetables, and animals which have no circulation, *respire* by their whole surface, or by means of vessels, which convey air to all points of their interior. Those only which have a true circulation breathe by a particular organ. The heart being in them a common point of departure and return for the blood, the vessels containing that fluid could easily be so arranged as to convey it to the lungs, after it had circulated through the body: this was obviously impracticable in instances, when the nutritive fluid is every where uniformly expanded, without being contained in vessels. Hence respiration by lungs or gills is a function dependent on that of circulation, and may be regarded as a remote consequence of those faculties which characterize animals.

Respiration presents to our observation two very different kinds of phenomena: 1st, the motions of the lungs, gills, or other instruments of breathing, or of parts connected with them, by which the former are alternately dilated and contracted for the admission and expulsion of air, and the latter are exposed to a current of water; and 2dly, the changes produced in the blood or other animal fluids, and in the air or water, in consequence of their mutual exposure in these organs. The first may be termed the *mechanical*, and the second the *chemical* phenomena of respiration. The former, including all the modifications which breathing undergoes in laughing, crying, and sighing, in coughing, sneezing, hiccupping, in straining or holding the breath, &c. have been fully considered under the article LUNG; in which the anatomy of the organs of respiration in man is also fully detailed. In the articles MAMMALIA, BIRDS, FISHES, REPTILES, INSECTS, and VERMES, the breathing organs, and their mechanical phenomena in animals, are considered. The chemical phenomena are the object of the present article.

The functions of the respiratory organs are closely connected with the other great processes of the animal economy. The heart, brain, and lungs, more particularly influence each other, and present, in their mutual relations, numerous and highly interesting considerations for the physiologist. On these points we refer to HEART, LUNGS, and NERVOUS System.

In the following article we shall speak, 1st, of the quantity of air received into the chest; 2dly, of the changes which this undergoes in breathing, as they have been made out by researches on the respiration of man and the mammalia; 3dly, of the changes produced in the blood; 4thly, of the various explanations of the mode in which these changes are produced; 5thly, of the respiration of the different gases; 6thly, of the chemical phenomena of respiration in other animals, and 7thly, of animal heat.

1. *Number of Respirations, and Quantity of Air respired.*—“It appears,” says Dr. Thomson (System of Chemistry, v. 5. p. 732.), “that the number of respirations made in a given time differs considerably in different men. Dr. Hales reckons them at 20 in a minute. A man, on whom Dr. Menzies made experiments, breathed only 14 times in a minute. Mr. Davy informs us that he breathes between 26 and 27 times in a minute. I myself make about 19 respirations at an average. The average of all is 20. Now 20 in a minute make 28,800 in 24 hours.”

In his “Inquiry,” p. 102, et seq. Mr. Ellis has brought together, from the most authentic sources, a statement of the facts hitherto collected concerning the quantity of air ordinarily inspired. To ascertain this point, many modes of experiment have been adopted, and the conclusions which have been drawn from them very widely differ. Borelli estimated the bulk of air taken in at a single inspiration at 15 cubic inches (de Mot. Animal.); Mr. Kite from 12 to 17 (Essay on Apparent Death, p. 24.); Dr. Goodwyn at 14 (Connection of Life with Respiration, p. 28, et seq.); Mr. Davy from 13 to 17 (Researches, p. 410 and 433.); and Drs. Jurine, Hales, Haller, and Sauvages, at 40 cubic inches. With the conclusion of these latter authors the experiments of Dr. Menzies nearly coincide, and as the methods which he adopted seem less liable to objection than those of any other author, it may not be improper shortly to give the detail of them. He procured an allantoid, and fixed to it a machine consisting of two pretty large tubes, joined at right angles, nearly in the form of a common brass cock. One end of the horizontal tube was connected with the allantoid, and the other received into the mouth, while the upright tube, which rose from its centre, communicated

## RESPIRATION.

with the atmosphere. The tubes were large, and valves, made out of an allantoid, were affixed to the end of the upright tube, and to that attached to the allantoid, so that the air, when expelled from the lungs, should not escape into the atmosphere, nor return from the allantoid, after having once entered it. Precautions were taken also, by covering the mouth and nostrils, to prevent any air from passing in or out of the lungs, except by the tubes above mentioned. Things being thus prepared, he began to respire, and did not remove his mouth from the tube till he had filled the allantoid, taking care to stop his nostrils during expiration. The allantoid was filled, in repeated trials, by about 56 expirations, as natural as possible; and as its capacity was 2400 cubic inches, the average bulk of air thrown out of the lungs by each expiration, was 42.8 cubic inches. He then fixed another allantoid, whose capacity had been previously ascertained, to the end of the upright tube; and having filled it with atmospheric air, he inspired the air from one allantoid and expired it into the other, and the quantities were found to be nearly the same. Several persons of the middle size repeated this experiment with nearly the same result; the difference being scarcely ever more than one or two cubic inches. By another mode of experiment, first proposed by Boerhaave, of plunging a man into a tub of water up to his chin, and judging of the dilatation of the lungs from the ascent and descent of the water, he obtained, by several trials, nearly the same results; and when these same men were made to breathe from and into the allantoids, in the manner above described, the correspondence by the two methods was almost complete. (Menzies on Respiration, p. 21, et seq.) As there seems no obvious source of inaccuracy in the processes here employed, and their results so remarkably coincide; and as they present the average bulk deduced from 56 respirations, we may conclude, says Dr. Bostock, that 40 cubic inches is the quantity of air employed in an ordinary act of respiration. *Essay on Respiration*, p. 34. *Inquiry into the Changes*, &c. § 85.

Messrs. Allen and Pepys endeavoured to determine the quantity of air received into the lungs in an ordinary inspiration: 3460 cubic inches of atmospheric air were passed through the lungs in 11 minutes, by 58 respirations. As, on ordinary occasions, the person breathed 19 times in a minute, it is inferred that, by multiplying the time consumed in the experiment by the number of natural respirations in a minute, and dividing the whole bulk of air by the product, we obtain the true bulk of air received into the lungs at each natural inspiration; thus  $11 \times 19 = 209$ ; and  $\frac{3460}{209} = 16.5$  cubic inches, the quantity of a single natural inspiration. (*Phil. Trans.* 1808, p. 256.) Mr. Ellis justly observes, that not only do the efforts of the mind, and the operations of the apparatus, interfere greatly with the natural actions of the respiratory organs, but the gross quantity of air received in 58 preternatural inspirations can never with justice be assumed as a true measure of the quantity breathed in 209 natural respirations. The experiments of Dr. Menzies therefore still seem the most unexceptionable on this subject.

The difficulty in arriving, by experiment, at certain conclusions respecting the volume of air taken into the lungs in each inspiration, may arise from a difference in the state or capacity of those organs in different individuals; from the relative vigour or debility of the muscular powers carrying on the respiratory function; from the circumstances in which the animal is placed; the composition of the air itself; or the manner in which it is breathed. In many modes of experiment also, the friction between the

air and apparatus employed, or the resistance which this latter may create to the ordinary process, will greatly vary the result: and considerable errors must likewise have arisen from the variation in bulk, occasioned by the change of temperature, which the air, during its respiration, suffers; from the difficulty of breathing in a natural manner when the mind is directing that process; and from the embarrassments opposed to the natural action of the respiratory organs by the contrivances adapted to them.

It will not be denied, that the size and capacity of the chest must, in a certain degree, regulate the quantity of air which is taken into, or expelled from it; and since respiration is neither wholly a voluntary nor an involuntary act, but, within certain limits, partakes of the nature of both, and is carried on by the exertion of muscular powers, the bulk of respired air must vary also, either from an alteration in the action of these powers, or from a change in the will of the agent who exerts them. This may be illustrated by considering the different quantities of air taken into the lungs in different states of natural and forced respiration. Dr. Goodwyn, supposing a person at death to make a complete expiration, endeavoured to ascertain the bulk of air then remaining in the lungs, which he estimated at 109 cubic inches. (*Connection of Life with Respiration*, p. 27.) This estimate he formed by measuring the capacity of the chest, in subjects who had died a natural death by disease, previous to which the expiratory powers must have been much weakened, and unable, in consequence, to expel so much air as when in a state of health and vigour; and in such cases, therefore, expiration might be final without being complete. Mr. Cruickshank observes, accordingly, that the lungs in the dead body, (though expiration is the last action of life,) always retain more air than is given out at several expirations. (*On Insensible Perspiration*, p. 97.) By a very different mode of experiment, we find Mr. Davy to conclude that his lungs, after a forced expiration, contain only 32 cubic inches of air, when it is reduced to the temperature of 55°, but which, by the heat of the lungs, and saturation with moisture, are increased to 41 cubic inches; and, after a natural expiration, they contained 118 cubic inches (*Researches*, p. 409, 410.); so that the difference between the two states of natural and forced expiration is 77, which is somewhat more than Dr. Menzies allows, who remarked that many men, after an ordinary expiration, could still expel from their lungs 70 cubic inches of air. (*Diff. on Respiration*, p. 31.) Mr. Davy adds, that his estimate of 118 cubic inches, as the capacity of the lungs after natural expiration, agrees very well with that of Dr. Goodwyn, who makes it about 109; and, on the supposition that the general debility which precedes the ordinary extinction of life, so weakens the expiratory muscles, as to disable them from making so complete an expulsion of the air, as they can effect when in health and vigour, the agreement is very striking; for nearly the same quantity of air would, in that case, remain in the lungs at the period of natural death, as after that of ordinary expiration.

Messrs. Allen and Pepys found that the healthy lungs of a stout man, five feet ten inches high, contained 108 cubic inches of air after death. *Phil. Trans.* 1809, p. 410, et seq.

Dr. Bostock conceives, that Dr. Goodwyn's estimate of 109 cubic inches of air remaining in the lungs after complete expiration, is not very remote from the truth; and he objects to Mr. Davy's mode of ascertaining the residual air of the lungs after a forced expiration, from a supposition that the hydrogen gas which he inspired for that purpose was not, in consequence of its low specific gravity, uniformly

formly diffused through all the cavities of the lungs; and therefore, that the proportions of the gas discharged could furnish no accurate estimate of those which were retained. (Essay, p. 17—25.) But Mr. Dalton has shewn, that hydrogen gas and atmospheric air intermix, when the former is kept in a phial above the latter, and communicating only by the small tube of a tobacco-pipe; and both in a state of rest. (Manchester Memoirs, vol. i. new series.) How much more readily than may this be expected to take place, where the gases are exposed to so large a surface, such great agitation, and increased temperature, as they must have been in the experiments of Mr. Davy. Neither is the small quantity of air, which Mr. Davy assigns, so incompatible, as Dr. Bostock supposes, with the anatomical structure of the thorax; for if we call to mind the space which the heart and the lungs occupy, and recollect, that, under a violent exertion, the chest is made to contract in every direction, and more especially by the ascent of the diaphragm nearly to the fourth or fifth rib, there is no difficulty in imagining the quantity of air in the lungs, in such circumstances, to be nearly that which Mr. Davy's experiments assign.

From a review, therefore, of all the facts and experiments above stated, we venture to draw the following conclusions, as approaching nearest to the truth. First, then, according to Mr. Davy, the lungs contain, after a forced expiration, a bulk of air equal to about 41 cubic inches; and according to the same author and Dr. Goodwyn, they contain, after a natural expiration, from 109 to 118 cubic inches; therefore the state of forced is to that of natural expiration, as 41 to 118. Secondly, according to Dr. Menzies, 40 cubic inches of air are received into the lungs at each ordinary inspiration; therefore the state of natural expiration to that of natural inspiration will be as 118 to 158. Mr. Davy found likewise, that by a forced expiration after a forced inspiration, he could expel from his lungs 190 cubic inches of air, and Dr. Menzies often found it to amount to 200 inches; therefore the state of greatest exhaustion of the lungs is to that of greatest repletion, as 41 to 231. But the 41 cubic inches of air, when inspired at temperature 55°, occupied a bulk equal only to 32; and therefore, by the same rule of proportion, 190 cubic inches, inspired at the same temperature, will be increased to 241.5; consequently, the greatest diminution of the capacity of the chest to its greatest expansion will be as 41 to 241, in the case of Mr. Davy. But these numbers must be considered as indicating proportions only, the absolute quantities being different in different persons. These facts decidedly shew how much the volume of air in the lungs will, at all times, depend on the relative capacity of those organs, on the more or less vigorous state of the expiratory powers, and on the degree of voluntary exertion with which the function may be performed.

The circumstances in which the animal may happen to be placed, will render this variation still more striking. Thus, from the experiments of Mr. Kite (On Apparent Death, p. 27. 29.) and Mr. Coleman (On Suspended Respiration, p. 7, et seq.), we learn, that in the act of drowning, animals are able to expel almost all the air which their lungs contain, by which those organs are brought into a state of collapse. Dr. Goodwyn, on the other hand, found, that in three executed persons, the lungs were expanded almost to their utmost extent, containing 250, 262, and 272 cubic inches of air (Essay, p. 25.); and Mr. Coleman observes, that when, previous to their suspension, he secured the trachea of animals by a ligature at the instant an inspiration was made, in less than four minutes they ceased to struggle, though the whole of the air was confined within the lungs,

and no obstruction to the passage of the blood existed from their collapse (p. 111—138). Dr. Baillie also has often observed the lungs filling the chest, and distended with air and mucus, in persons who have died asthmatic; so that to die and to expire are by no means synonymous terms,—an observation long since made by Mayow, who remarked, that if air be drawn into the lungs, and the mouth and nostrils afterwards closed, “*quamvis inflati maneat pulmones, mori tamen necesse erit, quia non licet expirare.*” (Tractat. Quinque, p. 300.) If indeed we reflect, that during submersion in water no fresh air can enter into the lungs, but that all which they contain may freely escape; and if we consider, that before suspension by the neck in the human subject, a deep inspiration, under the influence of fear, as Dr. Goodwyn observes, is made, and that no air can afterwards pass out, if the cord completely close up the trachea; it is reasonable to expect, that this variation in the bulk of air contained in the lungs should obtain, under the very different circumstances in which respiration is brought to a stand.

How much the composition of the air itself, and the manner in which it is breathed, will vary the bulk of residual air in the lungs, we may collect from the experiments of various authors. Dr. Hales moistened a bladder, and fixed to it a socket, both of which would contain 74 cubic inches of air. Having blown up the bladder, he put the small end of the socket into his mouth, and, at the same time, pinched his nostrils close, that no air might escape through them, and he then breathed to and fro the air contained in the bladder. In less than half a minute, he found a considerable difficulty of breathing, and was forced after that to draw his breath very fast; and at the end of the experiment, the suffocating uneasiness was so great as to oblige him to take away the bladder from his mouth. Towards the end of the minute, the bladder was become so flaccid that he could not blow it above half full, with the greatest expiration that he could make. (Statical Essays, vol. i. p. 238.) When also Mr. Davy respired atmospheric air in a natural manner, he took in, he says, only 13 cubic inches and expelled 12.7, so that only about  $\frac{1}{7}$  part of the original bulk was retained; when he made one respiration of 100 cubic inches of air, the diminution was to 99, or  $\frac{1}{100}$ ; when, after a complete exhaustion of his lungs, he respired 141 cubic inches of air, once only for one-fourth of a minute, they were reduced to 139, or  $\frac{1}{76}$ th nearly; and when 161 cubic inches were breathed for about a minute, their bulk was diminished to 152, or  $\frac{1}{74}$ th (Researches, p. 432—435.);—in every case, the diminution augmenting with the repetition of the respiration, and consequent impurity of the air, and distress of the respiratory organs. So likewise, when Dr. Henderfon breathed from and into the gasometer 600 cubic inches of air for four minutes, they were reduced to 570, or lost  $\frac{1}{10}$ th of their bulk; and he adds, that he held on respiring until the sense of oppression about the chest obliged him to desist. (Nicholson's Journal, May 1804.) These distressing symptoms, brought on by the repeated breathing of the same quantity of air, were felt in a still greater degree by Mr. Kite; for on respiring 591 cubic inches of atmospheric air from and into a bladder, he experienced, in one minute, great anxiety at the breast, which in half a minute more became intolerable; his face swelled, became black, and felt exceedingly hot, and sparks of fire danced before him; loss of sight, giddiness and confusion of the senses succeeded, and at the end of little more than two minutes, he fell back into a chair. He was relieved by fresh air, but remained confused and giddy (Essay on Apparent Death, p. 25.) The amount of the diminution of

## RESPIRATION.

of respired air, says professor Pfaff, depends not only on the *time* during which a given volume of air is respired, but principally on the magnitude of the volume of air itself; it must be proportionally less the greater the quantity inspired. He breathed 144 cubic inches of air once only in the time of ten or twelve seconds, and the diminution was four cubic inches, or  $\frac{1}{36}$ th of the primitive volume; when he respired the same volume of air twice, during twenty seconds, it lost eight cubic inches, or  $\frac{1}{9}$ th; and when it was thrice respired, during thirty seconds, the diminution amounted to twelve cubic inches, or  $\frac{1}{12}$ th of the primitive volume. (Nicholson's Journal, December 1805.) Now, in all these cases, the volume of air respired was precisely the same, and could not, therefore, affect the ratio of diminution: but as the times were doubled and tripled, so nearly were the degrees of diminution. But the more frequently the same air is breathed, the more unfit does it become for respiration; and to this change of composition, more than to the time, or the magnitude of the volume of air, is the increased degree of diminution to be ascribed.

This will perhaps appear more striking, if we attend to what happens in respiring nitrous oxyd, which is composed of the same elements as atmospheric air, but contains a much larger proportion of oxygen. After exhausting his lungs, Mr. Davy inspired 108 cubic inches of this gas, which, when expired, were reduced to 99, or had lost  $\frac{1}{12}$ th of their bulk. When he made two respirations of the same quantity of the oxyd, the diminution was to 95, or about  $\frac{1}{12}$ th; and when he respired 102 cubic inches of nitrous oxyd, mixed with  $\frac{1}{5}$ th of common air, for half a minute, the volume of air, after the seventh expiration, was reduced to 62, or had suffered a loss equal to  $\frac{1}{3.5}$ . (Researches, pp. 394. 416.) Hence it appears, that in the natural respiration of atmospheric air, only a small diminution of its bulk takes place: that this diminution increases as the air becomes vitiated by repeated respirations, or is breathed in a preternatural manner: and that when a gas of the same elementary materials, but combined in very different proportions, is substituted into the place of pure atmospheric air, the diminution increases in a tenfold degree. Now, the repeated breathing of the same atmospheric air, has been shewn to bring on the most distressful symptoms, and at length an utter inability to continue respiration; and Mr. Davy tells us, that after a voluntary exhaustion of his lungs, he could respire the nitrous oxyd with accuracy, when stooping, for about half a minute, but, even then, strong sensations were produced, with fulness about the head rather alarming: that if the respiration extended to three-fourths of a minute, he could not rely on the accuracy of any experiment; and that the determination of blood to the head became, in less than a minute, so great as often to deprive him of voluntary power over the muscles of his mouth. (Researches, p. 392.) But respiration is a function carried on by the exertion of muscular powers, in a great degree obedient to the will; and the quantity of residual air in the lungs in preternatural respiration will at all times be much influenced by the manner in which the will exerts itself, and the degree in which the muscles are able to act. When, therefore, the power of the will over the muscles is in any degree diminished, or is wholly lost, or the muscles themselves are much weakened, a proportional derangement will take place in the respiratory function; and as, in the natural condition of the body, expiration is subsequent to inspiration, the ability to inspire will last longer than the ability to expire: consequently the cessation of the process is brought about by a failure in the expiratory powers. But if the expiratory powers

are unable to expel the air from the lungs, it must remain in those organs; and hence we see in all the foregoing examples, that the diminution in the volume of expired air was greater in proportion as the respiratory organs suffered distress or oppression, and amounted even to more than one-third of the air inspired, when all voluntary powers ceased. Inquiry, &c. § 86—92.

From the above data it may be estimated, that by each ordinary expiration one-seventh part of the whole contents of the lungs is discharged, and that by the most violent expiration somewhat more than four-sevenths of the air contained in them is evacuated. Supposing that each respiration occupies about three seconds, a bulk of air nearly equal to three times the whole contents of the lungs will be expelled in a minute, or about 4114 times their bulk in 24 hours. The quantity of air respired during the diurnal period will be 1,152,000 cubic inches, or 666 $\frac{1}{2}$  cubic feet.

II. *Changes produced in the Air.*—Although the ancients were not unacquainted with the general fact, that respiration produces a change in the air received into the lungs, the first accurate notions respecting this change, were furnished by the experiments of Boyle. He not only proved, by means of the air-pump, the absolute necessity of air to the support of animal life, but he farther discovered, that the action of the lungs is quickly suspended, unless they are furnished with a regular supply of fresh air. (Works, v. 1. p. 99, et seq.) "Animals, whose hearts have two ventricles, and no foramen ovale," says Mr. Derham, "as birds, dogs, cats, and mice, die under the action of the air-pump in less than half a minute, counting from the very first extraction, particularly in a small receiver." (Physico-Theology, p. 8.) The same position is corroborated by an experiment, exhibited before the Royal Society by Dr. Hooke. He cut away the ribs, diaphragm, and pericardium of a dog, whereby the lungs and heart were brought into view; and then dividing the windpipe, he introduced into it the nozzle of a pair of double bellows, and made, at the same time, several small punctures through the outer coat of the lungs. By blowing in a stream of fresh air, which continued to escape through the small apertures made in the lungs, he was enabled to keep those organs fully distended. As long as he supplied the lungs with air, the actions of life continued, and the heart beat very regularly; but, on intermitting the supply, the dog would immediately fall into dying convulsive fits; and revive again as soon as the lungs were filled with a stream of fresh air. The circulation through the lungs continued both during their distended and collapsed state, and as well when they were kept at rest, as during their state of motion; whence he concluded, that neither the motion of the lungs, nor the cessation of their motion, nor the stopping of the circulation of the blood through them, was the immediate cause of death; but the want of a sufficient supply of fresh air. Lowthorp's Abridg. Phil. Transf. v. 3. p. 66.

From these facts it was naturally concluded, that the air had undergone some important change during its continuance in the pulmonary vesicles, and a variety of hypotheses and conjectures were formed to account for this alteration. The knowledge which was then obtained respecting the air was, however, almost entirely confined to its mechanical properties, so that the theories of respiration, formed during this period, were necessarily crude and imperfect. Boyle perceived that the air, in passing through the lungs, became loaded with a quantity of aqueous vapour, and he farther supposed, that it acquired, what he calls, recremenitious steams (Works, v. 3. p. 371, et seq.); but respecting

pecting the nature of these steams he forms no conjecture. He observed also, that the air in which an animal had respired for some time, was considerably diminished in volume, an effect which he attributed to the loss of part of its elasticity or spring. The contemporaries of Boyle, for the most part, coincided with him in his ideas respecting respiration; there were, however, some philosophers, who supposed, that besides the addition of these vapours, the air, during its continuance in the lungs, imparted something to the blood. Among these, the first in point of genius and originality was Mayow of Oxford. He investigated the properties of the air, and the effects produced upon it by respiration, with great acuteness, and concluded, that a peculiar volatile spirit, which was one of the constituents of the atmosphere, was absorbed by the blood during its passage through the lungs. Borelli, Lower, Willis, and others, adopted opinions in many respects similar to that of Mayow; they imagined, that either a portion of the whole mass of air, or some particular constituent of it, was absorbed by the blood, and by this means converted this fluid from the venous to the arterial state. But so little real knowledge was at this time possessed respecting the composition of the atmosphere, that they entirely failed in their attempts to ascertain the nature of the matter absorbed, and their hypotheses appeared so extravagant, and so little founded upon truth, that their doctrines fell into discredit, became neglected, and at length were totally forgotten. *De Motu Anim.* p. 2a. prop. 113. *De Corde*, p. 159—165. Willis, *Pharm. Rat.* p. ii. p. 34.

Dr. Hales devoted much of his attention to this subject, and performed many experiments with a view to illustrate the manner in which the air is affected by the lungs; he concludes nearly as Boyle had done, that it acquires a noxious vapour, and that its elasticity is diminished. (*Statistical Essays.*) The learned Boerhaave confesses his inability to explain the changes which the air experiences by respiration. (*Prælect. t. 5. p. 169, et seq.*) The opinion of Haller was not materially different from that of Boyle and Hales; he had collected all the different theories which have been advanced upon this subject, and after reviewing them with his accustomed candour and perspicuity, he concludes, that the air, when it is emitted from the pulmonary vesicles, is combined with a quantity of water, and a peculiar noxious vapour, and has its elasticity diminished. (*Notæ ad Boerhaav. Prælect. t. 5. p. 170. Element. Physiol.*) Such was the imperfect state of our knowledge, when Haller wrote his *Elements of Physiology*! This noble monument of industry and genius was scarcely published, when Dr. Black commenced his experiments upon fixed air, and among other interesting discoveries, satisfactorily proved, that this peculiar gaseous substance is generated in the lungs during respiration.

“So early as the year 1757,” says this distinguished philosopher, “I convinced myself, that the change produced in wholesome air by breathing it, consists chiefly, if not solely, in the conversion of part of it into fixed air; for I found, that by blowing through a pipe into lime-water, or a solution of caustic alkali, the lime was precipitated, and the alkali rendered mild.” (*Black’s Lectures*, by Robison, v. 2. p. 87.) At a later period, Mr. Bewley detected the formation of carbonic acid in respiration by a method somewhat similar: he found, that on breathing through an infusion of litmus, the same change to a red colour was produced in it, as when it was exposed to the action of fixed air; and when, by adding a few drops of the water of potassa, the blue colour was restored to the infusion, it could again be made to disappear by super-

aturating it with the acid expired from the lungs. Priestley on Air, v. 5. p. 383.

The particular substance which constituted the wholesome part of atmospheric air, was not, however, known to Dr. Black at the time his experiments were made: and long before the compound nature of the atmosphere was ascertained, it had been supposed by many philosophers, that, to use the language of bishop Berkeley, “there was no such thing as a pure simple element of air. There is,” he adds, “some one quality or ingredient in the air on which life more immediately and principally depends. What that is, though men are not agreed, yet it is agreed it must be the same thing that supports the vital and the common flame; it being found that when air, by often breathing in it, is become unfit for the one, it will no longer serve for the other. This quality of the air is necessary both to vegetables and animals, whether terrestrial or aquatic; neither beasts, insects, birds, nor fishes, being able to subsist without air: and when air is deprived of this ingredient, it becometh unfit to maintain either life or flame, even though it should retain its elasticity.” (*Siris*, § 143, et seq. 2d edition.) Dr. Hooke asserted, that this ingredient or substance, inherent in, and mixed with the air, is like, if not the very same, with that which is fixed in saltpetre, by which, during combustion, inflammable bodies are dissolved. (*Micrographia*, p. 103.) The same opinion was afterwards held by Willis, Lower, and Mayow, all of whom likewise considered the nitrous quality of the air to act an important part in respiration. The last author, in particular, made experiments precisely similar to those which have lately been brought forward to prove, that both by the burning of a candle, and other combustible bodies, and by the respiration of animals, the nitro-aërial particles of the air were exhausted, whereby the volume of air was diminished, and the residual air was unable afterwards to support either life or flame. (*Tractat. Quinque*, p. 98, et seq.) The exhibition, however, of this peculiar, or nitro-aërial, part of the air in a distinct and separate form, we owe to the genius of Scheele and Dr. Priestley, who discovered, independently of each other, in the year 1774, pure or dephlogisticated air or oxygen gas. The atmosphere, which, until this period, had been regarded as a homogeneous elementary body, was discovered by these celebrated experimenters, to be compounded of two aëriiform fluids, possessing distinct properties, and having totally different purposes in the economy of nature. These substances, which have since obtained the names of oxygenous and azotic gases, were found to exist in the atmosphere, in the constant proportion of about 22 to 78. This great discovery, and the use which he made of it, enabled Dr. Priestley to propose the first consistent explanation of the phenomena of respiration that had ever been offered to the public; and, although the theoretical opinions on which that explanation was partly founded, no longer exist, yet it should never be forgotten that his experiments and discoveries first pointed out the true path of investigation; and have contributed, in a pre-eminent degree, to advance our knowledge of this most important function. The cause of the unsuitness of air, beyond a certain extent, to support life and flame, he proved to arise from the destruction of its pure part, or what has since been called its oxygen gas; and he concluded, that, in respiration, combustion, and calcination, which, in consequence of his peculiar theory, he styles phlogistic processes, it underwent precisely the same changes. *Philos. Trans.* 1776. *Obs. on Air*, v. 3. p. 9.

About a year after the publication of Dr. Priestley’s experiments, the celebrated and unfortunate Lavoisier pre-

presented a memoir on respiration to the French Academy of Sciences. (Mem. de l'Acad. des Sciences, 1777.) After paying a tribute of respect to the genius of Dr. Priestley, he proceeds to an accurate examination of his experiments, and the conclusions which were deduced from them. He agrees with the doctor in supposing, that the proportion of oxygen is diminished in air which has been respired, but upon a careful analysis of the residue, he finds it to differ from the air left after the calcination of metals, which is merely azotic gas, in containing a quantity of carbonic acid. He also observed, that the bulk of the air was somewhat diminished, and we learn in general from these experiments, that the changes produced in air by respiration, consist in the removal of part of the oxygen, in the addition of a quantity of carbonic acid gas, and in the diminution of its volume. He supposes that the azote is not affected by the process, and that it serves merely to dilute the oxygenous part of the atmosphere.

In this paper, M. Lavoisier does not mention the aqueous vapour which is so evidently discharged from the lungs by respiration; it is impossible that it could have been overlooked by so accurate an observer; we may therefore conjecture, that he omitted to mention it, because at this period he considered it as only diffused through the air expired from the lungs, by the process of evaporation, and not formed in consequence of the operation of any chemical affinities.

The conclusions of this philosopher respecting the changes produced by respiration upon the air taken into the lungs, are for the most part acquiesced in by modern physiologists, and the researches which have been since made upon this subject are principally directed, either to ascertain with more precision the proportion of the respective ingredients in the air of expiration, or to frame hypotheses to account for the operation of the lungs in effecting these changes.

Among the investigations, however, of a date subsequent to this memoir of Lavoisier, those of Messrs. Allen and Pepys, published in the Philosophical Transactions, 1808 and 1809, deserve peculiar mention, on account of their great accuracy, and the satisfactory manner in which they have consequently enabled us to determine some doubtful points.

*Quantity of Oxygen consumed.*—"A difficult and interesting question," says Dr. Boileau, "respecting the consumption of oxygen, is the absolute quantity of this gas consumed by respiration in a given time. The first calculations which were made upon this subject, in consequence of the imperfect nature of the apparatus employed, and of the want of a sufficient dexterity in the management of pneumatic experiments, were unavoidably vague and inaccurate. The difficulty was much increased by a circumstance first noticed by Dr. Crawford, and afterwards more fully investigated by M. Jurine of Geneva, and M. Lavoisier, that the respiration of the same animal in different states of the system, and under the operation of different external circumstances, affects the air in very different degrees. This curious fact, which affords an insight into some of the most important operations of the animal economy, must unavoidably produce great differences in the results of the best conducted experiments, and will render it impossible for us to arrive at more than an approximation to the truth. The circumstances which have been discovered to influence the chemical effects of the respiration are, the temperature of the air respired, the degree of muscular exertion, the state of the digestive organs, and the condition of the system as affected by fever; it is highly probable that other circum-

stances will be discovered, by multiplying and varying our experiments upon the living body."

An experiment performed by Lavoisier, upon a guinea pig, seems to have been the first in which a perfect apparatus, and the necessary degree of accuracy, were employed. (Mem. de l'Acad. des Sciences, 1780, p. 401—8.) The animal was confined over mercury, in a jar containing 248 cubic inches of gas, consisting principally of oxygen. In an hour and a quarter, the animal breathed with much difficulty, and being removed from the apparatus, the state of the air was examined. Its bulk was found to be diminished by eight cubic inches, and of the remaining 240 inches, 40 were absorbed by caustic potash, and consequently consisted of carbonic acid gas. Taking 100 parts of this air, these numbers will be as follows; the air was diminished to 96.5, or by 3.5 cubic inches, and of the remainder, 16.5 were converted into carbonic acid gas, and absorbed by potash, which reduces the quantity of air to 80 cubic inches. Towards the conclusion of the experiment, the air would be necessarily much less fit for performing the functions of the lungs than the air of the atmosphere, in consequence of the carbonic acid gas which it contained; but as the air employed was originally much purer than the atmosphere, the author supposes, that the quantity of oxygen destroyed, was probably about the same which would have been consumed under the ordinary circumstances of respiration.

The same philosopher performed a second experiment upon the same species of animal, with still more accuracy, in which pure oxygen was employed. (Ann. de Chimie, t. 5. p. 261, et seq.) This experiment continued during an hour and a half, and the animal being then removed from the jar, the air was analysed as in the former case: 1728 cubic inches of air were found to be reduced to 1673, *i. e.* had suffered a diminution of 55 inches, caustic potash absorbed about 229.5 inches, leaving a residue of pure oxygen. These numbers, estimated as in the former case, will be nearly as follows; 100 inches were reduced to 96.82, or by 3.18 inches, the potash absorbed about 19 inches, reducing the whole quantity of air to 77.82 parts. The quantity of carbonic acid was here somewhat greater than in the former experiment, which may be attributed to the air employed being pure oxygen, and to the process having been continued for a somewhat longer space of time than in the former instance. Upon the whole, the results correspond as nearly as can be expected, from the very delicate nature of the experiments.

Dr. Menzies first attempted to ascertain the quantity of oxygen consumed by a man, in the course of a day. He found by experiment, that one-twentieth part of air, which had been once respired, is converted into carbonic acid gas: this he concludes must have been oxygen, as that part of the air alone is affected by respiration. He conceives that 720 cubic inches of air are respired in a minute, of which consequently 36 will be consumed. From these data he estimates, that in the space of 24 hours, 51,840 cubic inches, or 17625.6 grains of oxygen, are consumed and converted into carbonic acid gas. In this calculation several important particulars appear to have been overlooked, and accordingly it will be found to differ from the results of the more accurate experiments, which have been since performed by M. Lavoisier, and Mr. Davy.

The experiments which were made by M. Lavoisier, in conjunction with his friend M. Seguin, were conducted with every possible attention to accuracy, and with an apparatus more complete than any which has ever been employed in physiological researches. An account of them is detailed in two papers in the memoirs of the Academy of Sciences

## RESPIRATION.

Sciences for the years 1789 and 1790; but notwithstanding the peculiar advantages under which they were performed, their results will not be found in all instances to coincide. M. Seguin was himself the subject of the experiments. The authors begin by pointing out the different effects which are produced by respiration, under the different circumstances in which the body is placed; and they farther remark, that individuals may probably differ in the absolute quantity of oxygen which they consume in the same circumstances. Making a due allowance for these variations, they conclude, that the mean consumption of oxygen by a man, during 24 hours, is somewhat more than 22 French cubic feet, or 46037.38 English cubic inches; a quantity of gas which will weigh 15661.66 grains troy.

Lavoisier was still continuing to pursue his experiments on this subject, and had constructed a very expensive apparatus, for ascertaining with still more precision the amount of the several changes produced by respiration, when he fell a sacrifice to the fury of Robespierre, and received sentence of death. He had already performed a number of experiments with his new apparatus, and earnestly requested a respite of a few days, in order to prepare them for publication; but his request was not granted. M. de la Place, who pronounced his eulogy, has fortunately given us the most important results: they will be found to differ in some particulars from the former experiments, though, with respect to the quantity of oxygen consumed, they nearly coincide. It is stated that a man in 24 hours consumes 15592.5 grains.

There are some experiments on this subject by Mr. Davy, which appear to have been executed with great accuracy. From a number of trials made upon his own respiration, he found, that 100 cubic inches of atmospheric air, after having once passed through the lungs, had lost between four and five parts of oxygen: hence he calculates, that 31.6 cubic inches of oxygen are consumed in a minute; this will give 45,504 inches in 24 hours, a quantity which will weigh 15471.36 grains. This estimate coincides nearly with that of M. Lavoisier, though it was obtained by a different process, and by the use of a different apparatus. We may, therefore, conclude, that between 45 and 46,000 cubic inches, or about 15,500 grains = 2 lbs. 8 oz. troy, is the average quantity of oxygen consumed by a man in 24 hours. Davy's Researches, p. 431—434. Essay on Respiration, p. 78—84.

In the series of experiments lately performed by Messrs. Allen and Pepys, an apparatus was employed, in which the volume of the air respired could be measured with great accuracy, and in which a large quantity (3 or 4000 cubic inches) could be respired; so that the source of error, to which experiments on a smaller scale are liable, from the influence of the residual air in the lungs, is much diminished. They caused a person to inspire, from a gasometer, 3460 cubic inches of atmospheric air, which were afterwards expired into another gasometer; and to both gasometers graduated scales were affixed, by which the quantities of air received and expelled could be accurately measured. The time occupied in the experiment was 11 minutes: about 58 respirations were made; and the deficiency in the whole volume of air, at the close of the experiment, amounted only to 23 cubic inches. One hundred parts of the expired air afforded, on analysis, 8.5 carbonic acid, 12.5 oxygen, and 79 nitrogen gas. (Phil. Transf. 1808, p. 254.) In an experiment on the respiration of another subject, the changes produced in the air were the same, but the quantity consumed was very different. The thermometer (Fahr.) being at 56°, and the barometer at 30°.3, 3300 cubic

inches of atmospheric air were inspired, and 3311 expired in 5½ minutes. One hundred parts of the expired air consisted of 8.5 carbonic acid, 12.5 oxygen, and 79 azote. When, therefore, twice the quantity of air was passed through the lungs in a given time, as great a proportion of its oxygen was consumed, and as much carbonic acid formed, as in a subject in whom only half the quantity was breathed. The experiment was repeated several times; and in one instance, 9890 cubic inches of air were breathed for 24½ minutes, with the loss of only 18 cubic inches; and 100 parts of the expired air then afforded, on analysis, 8 carbonic acid, 13 oxygen, and 79 nitrogen. (Ibid. 257.) Now the air employed in these experiments contained, in 100 parts, 21 oxygen and 79 nitrogen; and in the numerous analyses, which were made of this air after its respiration, the portion of oxygen that disappeared was exactly replaced by that of carbonic acid produced; so that, in every instance, these two gases formed together  $\frac{2}{3}$ ths of the respired air, the remaining 79 parts being pure nitrogen gas. It is, therefore, concluded, that the quantity of carbonic acid gas emitted is exactly equal, bulk for bulk, to the oxygen consumed. Ibid. p. 279.

In subsequent experiments on the respiration of a guinea pig, these chemists found, that when 310 cubic inches of atmospheric air were breathed for 25 minutes by this animal, its volume experienced no variation whatever; and the portion of its oxygen, which disappeared, was replaced by an equal bulk of carbonic acid. (Phil. Transf. 1809, p. 414.) Three experiments were made on the respiration of the guinea pig, in two of which the time occupied was 25 minutes, and in the third one hour. The animal was confined in a certain volume of air, which was changed successively, so that the same air may have been breathed more than once; while in the experiments of these gentlemen on human respiration, just detailed, the air was only once breathed. In all the three experiments with the guinea pig, 100 parts of the air breathed contained the same constituent elements, viz. 5 carbonic acid, 16 oxygen, 79 azote. (Phil. Transf. 1809, p. 413, et seq.) Wherefore, they justly conclude, that when atmospheric air alone is respired, even by an animal subsisting wholly on vegetables, no other change takes place in it than the substitution of a certain portion of carbonic acid gas for an equal volume of oxygen. Ibid. p. 427.

In respiration as nearly natural as possible, these gentlemen estimate the quantity of oxygen consumed on an average at 26.6 cubic inches, at the temperature of 50°, and barometrical pressure of 30°.4.

The changes occurring in respiration are influenced by various causes, which modify the actions of the capillary vessels. Crawford established by experiment, that less oxygen is consumed at a high than at a low temperature (Experiments on Animal Heat, p. 307.); and this was confirmed in the experiments of Lavoisier and Seguin (Mém. de l'Acad. des Sciences, 1789, p. 575.); a man consuming, at the temperature of 54°, 1344 cubic inches of oxygen in an hour, while, in an atmosphere at the temperature of 79°, he consumed only 1210 cubic inches. Crawford observed also, that in an animal placed in a warm medium, the venous blood approached to the arterial in colour. Hence it appears, that the high temperature counteracts those chemical changes which the blood undergoes in the extreme vessels; and that the diminution in the consumption of oxygen by respiration is owing to this cause, and not, as has been supposed, to the rarity of the air at the high temperature. If the consumption of oxygen were diminished from the latter cause, the blood ought to be even more completely venous:

than usual. The fact formerly known, that the consumption of oxygen is influenced by the food and the state of digestion, was confirmed and more accurately demonstrated by Lavoisier and Seguin. They found, that during digestion the consumption of oxygen was increased to 1800 or 1900 cubic inches in an hour. Exercise, too, increased the proportion consumed. It is stated that Seguin, in continuing the exercise of raising a weight of 15 pounds to a height of 613 feet during a quarter of an hour, consumed 800 cubic inches, which is at the rate of 3200 in an hour; and the same exercise, made during digestion, occasioned a consumption equal to 4600.

Notwithstanding, however, says Mr. Ellis, the necessity of oxygen gas to the continuance of respiration, and the great quantity of it that is thus daily consumed, many facts tend to prove, that, by the very constitution of that function, a necessary limit is placed to its consumption: and that this limit is determined, not by the purity of the air employed, but by some circumstances inherent in the animal system. It has been found, that the growth of vegetables is retarded by a great superabundance of oxygen (Ellis's Inquiry, § 14-40.); and that, although insects will live a considerable time in this gas, yet their breathing becomes oppressive, and they die (ibid. § 53.) long before the whole of it is consumed. There can be little doubt but that the other classes of inferior animals would, under the same circumstances, suffer in the same manner. In the experiment also made by Lavoisier on the guinea pig, already described, the animal is said to have breathed with much difficulty, although not more than one-fifth of the oxygen gas was consumed: but some experiments of the same author, at a later period, seem in opposition to this fact. In comparing together the phenomena of combustion and respiration, he observes, that much more combustible matter is consumed in a given time in vital air, than in that of the atmosphere, but that the same circumstance does not hold in respiration: for whether animals respire oxygen gas in its pure state, or mixed with a proportion, more or less considerable, of nitrogen gas, the quantity of oxygen which they consume is always the same. If a guinea pig, he adds, be kept for several days in oxygen gas, or in a mixture composed of fifteen parts nitrogen and one of oxygen, preserving constantly these proportions, the animal in both cases continues in his natural state: his respiration and circulation do not sensibly appear to be either accelerated or retarded: his temperature remains the same, and he has only, when the proportion of nitrogen gas is too great, a slight disposition to drowsiness. Mem. de l'Acad. 1789.

The results of Mr. Davy's experience, however, do not correspond with these conclusions of Lavoisier. He introduced a mouse into a jar containing an atmosphere composed of 10.5 cubic inches of oxygen, and three inches of nitrogen gas. In half an hour the animal appeared to suffer much, and, in about an hour, lay down on his side, as if dying: in an hour and a quarter he was withdrawn from the jar alive, but motionless. The residual air, on being analysed, was found to have lost only 2.1 cubic inches of its oxygen gas, and consequently 8.4 inches of that gas still remained. Another mouse, which was put at the same time into a jar containing 15.5 cubic inches of atmospheric air, was taken out through the mercury alive, but unable to stand, in 50 minutes: and on analysing the residual air, 2.7 cubic inches of its oxygen were consumed. Hence it appears, that the mouse in atmospheric air consumed nearly one-third more of oxygen in 50 minutes, than the other mouse did in an hour and a quarter, when placed in a jar containing so large a portion of oxygen. (Researches, p. 443.)

The results of these experiments on mice are corroborated by those made by Mr. Davy on his own respiration; for he found, that he consumed much less oxygen gas when he respired it pure, than when, for the same length of time, he breathed atmospheric air; and the quantity of carbonic acid formed in the first case, was but little more than half that obtained by the respiration, for the same time, of atmospheric air. (Ibid. 442.) Messrs. Allen and Pepys state, on the contrary, that when pure oxygen gas is breathed, more of it is consumed in a given time, and more carbonic acid formed, than in breathing atmospheric air. The experiments of Davy differ greatly therefore from those of Lavoisier as to the effects produced by the respiration of oxygen on the animal system; for, while the latter philosopher informs us, that this gas may be respired for many days without inconvenience, Mr. Davy has shewn that the animal dies long before the whole of it is consumed. Truilling, therefore, to the accuracy of Mr. Davy's experiments, as in all respects supported by analogy, we infer, that an excess of oxygen gas in the air that is breathed, is not suited to the due maintenance of the respiratory function: and, on the other hand, the oppressive symptoms which the respiration of impure air occasions, as well as the results of Lavoisier's experiments, in which nitrogen superabounded, equally instruct us, that a deficiency of this gas is alike unsuited to it. Consequently, we may conclude, that the atmosphere, as it is naturally composed, is best adapted to the economy of the animal system; but that this system is, at the same time, so constituted, as to be able to bear great variations in the composition of the air without immediate injury to the powers of animal life.

When, however, this variation proceeds to a certain extent, the air is no longer capable of supporting vital action; but different animals, when confined in given volumes of air, possess the power of prolonging this action in very different degrees. Thus insects, worms, fishes, and the amphibia, live until all the oxygen gas of the air is nearly or entirely consumed (Ellis's Inquiry, § 53, et seq.); while birds die in a given quantity of air before they have consumed two-thirds of its oxygen (ibid. § 84.), and a mouse and guinea pig expire when about three-fourths of this gas have disappeared. Dr. Priestley observed, that if a mouse can stand the first shock of being put into impure air, or has been habituated to it by degrees, he will live a considerable time in air in which other mice will instantaneously die. (Experiments on Air, p. 257.) When, however, death does happen to animals in a given volume of air, it must arise either from the noxious operation of the nitrogen gas that is always present, or from that of the carbonic acid, which is formed; or it must proceed from the deficiency, or total absence, of oxygen gas. Now, although nitrogen gas do not of itself support life, yet we have no evidence that it exerts any injurious effects on the animal system. In vegetation, and in the respiration of the inferior animals, it has been shewn to be wholly inactive; and when, in the experiment of Lavoisier, it constituted  $\frac{1}{5}$ ths of the air employed, a degree of drowsiness only seems to have been induced by it. That it is entirely passive, is still farther confirmed by an experiment of Lavoisier, who found that hydrogen gas, mixed in due proportion with oxygen, would serve the purposes of respiration as well as the air of the atmosphere. We have no proof that nitrogen is able to enter the vessels so as to produce any direct operation on the blood,—an effect which is still farther forbidden by its incapacity of uniting with that fluid. We may therefore conclude, that nitrogen gas, when respired, neither suffers any change itself, nor produces any direct operation on the animal system.

The only other gas to which the death of animals, in these circumstances, can be ascribed, is carbonic acid, which, however, when formed by respiration, does not seem destructive to animal life. Dr. Goodwyn observes, that when the same air is breathed several times, so as to increase the quantity of carbonic acid, its noxious operation is to be attributed not to the presence of this acid, but to the deficiency or absence of oxygen gas (Connection of Life, &c. p. 66.); and when Spallanzani, by means of an alkaline substance, abstracted this acid as soon as formed by the respiration of birds and quadrupeds, he did not find that they lived longer in a given bulk of air than when it was suffered to remain. (Memoirs on Respiration, p. 318.) Dr. Higgins observes, that debility, convulsions, and death, follow the successive diminution of the oxygen gas of the air in respiration, long before the whole of that gas is consumed, although the carbonic acid that is generated be, in the mean time, carefully withdrawn. (Minutes of a Society, p. 160.) Indeed, we might in this, as in former examples, be led to suppose, that neither the carbonic acid formed in respiration, nor the nitrogen gas employed in that process, would exert any positively destructive operation on the animal powers, since both of them must, at all times, necessarily be present in the system; and seeing, moreover, that the abstraction of oxygen gas alone is sufficient to account for the fatal effects which ensue, it must be deemed unnecessary to resort to the supposed agency of any subordinate cause. Inquiry, &c. § 127—130.

*Quantity of Carbonic Acid produced.*—Having ascertained the proportion of oxygen which is consumed in respiration, it next remains for us to determine the quantity of carbonic acid gas which is produced. It appears that Dr. Black first demonstrated its existence in air emitted from the lungs, and that Lavoisier afterwards examined it with more accuracy, and found that the air, in which an animal had expired, contained about one-sixth of its bulk of carbonic acid gas. (Acad. des Sciences, 1777.) In the experiment which this philosopher performed with a more perfect apparatus, upon a guinea pig confined in oxygen, the carbonic acid amounted to nearly one-fifth of the bulk of the whole air employed, when the animal had been detained in the apparatus until the air was reduced into a state no longer fit for respiration. (Annales de Chimie, t. 5. p. 261, et seq.) These experiments, however, only prove what proportion of carbonic acid gas will render air incapable of supporting life, without acquainting us with the quantity of this gas produced under the ordinary circumstances of respiration.

M. Jurine of Geneva, appears to have been the first who attempted to calculate the absolute quantity of carbonic acid formed by the respiration of man; he imagined that it constituted about one-tenth part of the air emitted from the lungs. (Encycl. Method. Médecine, v. 1. p. 494.) Dr. Menzies instituted a set of experiments to discover the absolute quantity generated in a given time; he infers from them, that  $\frac{1}{7}$ th part of air which has been once respired, is carbonic acid, and estimates, that a man, in 24 hours, sends out from the lungs 51,840 cubic inches, or nearly 4lbs. troy; but this estimate is probably over-rated. Essay, p. 50.

The circumstances which have been already pointed out, as influencing the consumption of oxygen, have at least as powerful an effect upon the production of carbonic acid gas. Accordingly we shall find the calculations of the most accurate experimenters upon this subject so widely different from each other, that it seems scarcely possible to arrive at any tolerable degree of certainty.

M. M. Lavoisier and Seguin, in their first memoir of

1789, estimate the average quantity of carbonic acid gas, formed by a man in 24 hours, at 17720.89 grains troy; in their subsequent memoir, published in the following year, this quantity is diminished to 8450.24 grains; and in the eulogy of Lavoisier by La Piazze, it is stated, that Lavoisier, in his last experiments, reduced it still lower, to 7550.40 grains. Mr. Davy, on the contrary, whose experiments seem to have been performed with great exactness, though with a less complicated apparatus than that employed by the French chemists, supposes the carbonic acid formed in 24 hours to amount to 17811.38 grains (Recherches, p. 434.), a quantity which is not very different from that first announced by Lavoisier.

Mr. Murray found that he expired 265 cubic inches of air in 30 seconds, and he discovered in this 16.57 cubic inches of carbonic acid. Making a deduction for the small quantity of this acid contained in the inspired air, he assumes 16 cubic inches as the quantity formed by respiration in 30 seconds. He calculated the quantity of oxygen consumed at 19 cubic inches: the ratio, therefore, between the calculated quantity of oxygen consumed, and the actual quantity of carbonic acid formed, was as 100 to 84.5. Syst. of Chemistry, v. 4. p. 494.

Messrs. Allen and Pepys conclude from their experiments, that the atmospheric air expelled from the lungs usually contains from 8 to 8.5 per cent. of carbonic acid, and that the proportion of acid in no case exceeds 10 per cent. They estimate the quantity of acid thrown off in 11 minutes at 302 cubic inches, which is about 27.45 per minute; and supposing the production uniform for 24 hours, the total quantity in that period would be 39,534 cubic inches, weighing 18,683 grains, or rather more than 11 oz. troy. Phil. Transf. 1808.

If a larger quantity of air be passed through the lungs in a given time, more carbonic acid is formed, but it still preserves the same ratio to the other component parts of the expired mals. Thus, 3300 cubic inches of air were inspired by one person in 5½ minutes, and as each 100 parts contained 8.5 of carbonic acid, the whole acid formed in this time was 281.42 cubic inches. The first and last portions of a single expiration differ considerably in their proportions of carbonic acid, because the former consists principally of air contained in the fauces, trachea, and its larger branches, while the latter comes from the air-cells themselves. In small quantities of the first portions, given off by natural and easy expirations, the carbonic acid formed from three to five per cent. When an expiration was made as complete as possible, the utmost efforts being employed to press the air out of the lungs, 20.4 cubic inches were expelled, and the proportion of carbonic acid was 9.5. Now as the first portions contain only from three to five per cent., the last must have contained more than the average, or 9.5. When 300 inches of atmospheric air were repeatedly breathed, until the laborious state of respiration compelled the operator to desist, 100 parts of the expired air contained 9.5 carbonic acid, 5.5 oxygen, and 85 azote. When a similar trial was repeated until the operator became insensible, 100 parts of the air contained 10 carbonic acid, 4 oxygen, and 86 azote. (Phil. Transf. 1808.) When 3260 cubic inches of gas, consisting of 97.5 oxygen, and 2.5 azote in 100 parts, were respired for 9 minutes and 20 seconds, the expired air measured 3193 inches, and contained, in 100 parts, 11 carbonic acid, 83 oxygen, 6 azote. Here, therefore, 37.64 cubic inches of carbonic acid were emitted from the lungs in one minute by the same individual, who produced 27.45 per minute, when he breathed common air. In another instance, 3420 cubic inches of similar air were breathed for 7' 25":

the expired air measured 3362. The first 250 cubic inches consisted, in 100 parts, of 9 carbonic acid, 25 azote, 66 oxygen; the last, of 12.5 carbonic acid, 5.5 azote, 82 oxygen: 100 parts of the whole expired air consisted of 12 carbonic acid, 6.5 azote, 81.5 oxygen. The whole quantity of carbonic acid gas emitted in this experiment was 396.78 cubic inches. *Ibid.*

The result, which shews a greater evolution of carbonic acid when oxygen is respired, is totally adverse to those obtained by Mr. Davy, and already mentioned. We do not therefore feel authorized in determining whether, in general, an increase in the quantity of oxygen employed augments the carbonic acid evolved, or whether the proportion of the latter depends on the condition of the respiratory organs, or variations in the exercise of their functions.

If it should be allowed, as the greatest number of investigations on the subject tends to prove, that the carbonic acid formed in respiration be less in bulk than the oxygen gas, which disappears, yet the weight of the compound is increased by the addition of carbon, derived from the animal system. Lavoisier and Seguin estimated the weight of oxygen gas consumed by a man in 24 hours, at 15661.66 grains; and that of carbonic acid produced in the same space of time, at 17720.89 grains; the carbon constituting  $\frac{1}{17}$ th of the weight of the acid formed. In the experiments of Mr. Davy, the volume of oxygen gas that disappeared every minute was 31.6 cubic inches, and that of carbonic acid produced 26.6 inches. But one cubic inch of oxygen gas weighs 0.3474 of a grain, and therefore 31.6 cubic inches will weigh 10.97784 grains: again, one cubic inch of carbonic acid weighs 0.476 of a grain, and therefore 26.6 cubic inches will weigh 12.4222 grains. From these facts it would seem, that the proportion of carbon in the carbonic acid of respiration is much less than that which forms the same acid in combustion. For 100 parts of carbonic acid, formed by burning the diamond, contain, according to the very accurate researches of Allen and Pepys (*Phil. Trans.* 1807) 20.72 or 28.81 of carbon: and the proportion of carbon in 100 parts of acid is 28.77, when it is formed from charcoal and oxygen. (*Murray's Chemistry*, ed. 3. v. 2. p. 487.) But there are some points of the subject requiring the elucidation of further researches.

*Alteration in the Bulk of the respired Air.*—On no point of the respiratory process are the recorded results of different inquiries more at variance with each other, than about the question of the change in volume of the air, and the amount of that change. At first, it was generally believed, that the respired air undergoes some loss; and this opinion maintained its ground until very lately, although experiments were published, in which no such loss was observed. The most accurate modern researches are much in favour of the opinion, that the bulk of the atmosphere is not affected by breathing; and this view of the subject is the most generally entertained in the present day. Some think, that, although the volume of the respired air is not affected in ordinary natural breathing, it may be altered under particular circumstances. The determination of the question concerning the volume of the air, is closely connected with another respecting its absorption by the blood. We shall detail the facts and arguments on both sides, and point out that which has the most numerous and strong proofs in its favour.

The diminution of bulk was early noticed by Boyle, who estimated it at about  $\frac{1}{17}$ th of the air employed. Mayow, whose genius enabled him to anticipate so many important discoveries of modern chemistry, confined an animal in a glass vessel inverted over water, and, by the aid of a siphon, brought the water on the inside of the vessel to a level

with that on the outside. Having then marked the height of the water by pieces of paper affixed to the side of the vessel, he observed its gradual rise as the animal continued to breathe; and then, comparing the space occupied by the air at the commencement of the experiment, with that which it possessed when the animal ceased to breathe, he found that it was reduced about  $\frac{1}{17}$ th part of its bulk. (*Tractat. Quinque*, p. 104.) In the experiments of Dr. Hales, the degree of diminution varied from  $\frac{1}{17}$ th to  $\frac{1}{20}$ th of the air employed. *Statistical Essays*, v. 1. p. 230. v. 2. p. 320.

Lavoisier, in the first memoir which he published upon respiration, ascertained the degree of diminution with more accuracy, and stated, that air, when rendered unfit to support life, was reduced  $\frac{1}{10}$ th in bulk. (*Mem. de l'Acad.* 1777.) The experiments of Dr. Goodwyn afforded the same result.

The volume of air, taken into the lungs at a single inspiration, contained,

Phlogificated air	-	-	-	-	80
De-phlogificated air	-	-	-	-	13
Fixed air	-	-	-	-	2
					<hr/>
					100
					<hr/>

The volume of air, expelled from the lungs at the next succeeding expiration, contained,

Phlogificated air	-	-	-	-	80
De-phlogificated air	-	-	-	-	5
Fixed air	-	-	-	-	13
					<hr/>
					98
					<hr/>

*Connection of Life, &c.* p. 51.

In the account which Lavoisier gives of the first experiment upon the guinea pig, he found the diminution to amount to  $\frac{1}{17}$ th of the bulk of the air employed (*Mem. de l'Acad.* 1780, p. 401.); and in the second set of experiments, the diminution was found to be  $\frac{1}{17}$ d part (*Annales de Chimie*, tom. v. p. 261.); the greater absorption, in these cases, probably depending upon the greater purity of the air employed. In the experiments performed by Lavoisier, in conjunction with Seguin, upon the respiration of man, though in other respects so remarkable for their accuracy, there is no mention made of this circumstance, nor is it noticed by La Place, in his account of the experiments in which Lavoisier was engaged, immediately previous to his execution. In these instances we cannot determine whether Lavoisier conceived that no diminution actually took place, or whether he only neglected to notice it.

The general fact of the diminution of bulk in respired air, has been since confirmed by Mr. Davy, though the exact degree of absorption varied so much in his different experiments, that it is difficult from them to fix upon a quantity which may indicate the ordinary amount of this diminution. In the consideration of this question, as in the preceding one respecting the consumption of oxygen, and the production of carbonic acid, there are two distinct objects of inquiry. We may examine the degree of diminution produced in a given quantity of air, in which an animal has been confined, until it is no longer fit for supporting respiration; and in the second place, we have to ascertain the amount of the diminution which takes place in air, that has only once passed through the lungs, as is the case in the process of ordinary respiration. The first of these points only was examined by Lavoisier. Mr. Davy has made experiments upon both. In air which had only once passed through the lungs, he found the diminution in different trials

## RESPIRATION.

trials to vary from  $\frac{1}{3}$ th to  $\frac{1}{10}$ th: when he received the same air repeatedly into the lungs, it was found to be diminished as much as  $\frac{1}{5}$ th of its original bulk. (Researches, p. 431—435.) The former experiments, however, alone indicate the effects of natural respiration, and taking an average of their results, the amount of the diminution will be about  $\frac{1}{10}$ th part of the whole air received into the lungs.

Mr. Murray of Edinburgh made some experiments on the alterations produced in the air by natural respiration, from which he calculates (for the quantity of air inspired was not measured) that there is a loss of 6 cubic inches in 265. System of Chemistry, vol. iv. p. 493, 494.

Messrs. Allen and Pepys, whose experiments we shall presently allude to, as affording the strongest arguments against a change of volume in the respired air, in natural breathing, met with a different result, when the circumstances of the experiment were changed. In their fourteenth experiment, 300 cubic inches of atmospheric air were, in the space of three minutes, passed eight or ten times through the lungs, until respiration became extremely laborious, and the operator was compelled to desist. On analysing the respired air, it was found to contain, in 100 parts, only 5.5 oxygen, 9.5 carbonic acid, and 85 parts of nitrogen gas. In the fifteenth experiment, which occupied also about three minutes, until the operator became quite insensible, the same quantity of air was employed, and afforded, by analysis, nearly the same results; for it contained, in 100 parts, 4 of oxygen, 10 of carbonic acid, and 86 of nitrogen. In the former experiment we observe, therefore, an increase of 6 parts of nitrogen, and a loss of 6 parts of oxygen; and in the latter, the oxygen had lost 7 from 21, and the nitrogen had gained 7 upon 29. (Phil. Trans. 1808, p. 260.) Hence it is inferred, that when, as in these experiments, respiration is attended with distressing circumstances, there is reason to conclude that a portion of oxygen is absorbed. Ibid. p. 280.

In some experiments on the respiration of rabbits and of guinea pigs, Mr. Berthollet found that the bulk of acid gas produced did not quite equal that of the oxygen which disappeared; so that the loss of oxygen appeared to vary from 1.07 to 4.09 per cent.

We proceed to state the result of those inquiries, in which the volume of the air has been found not to undergo diminution in the act of breathing. Among the earliest experiments of Dr. Priestley on respiration is one, in which he confined a mouse in a jar containing a given quantity of air, which was inverted over mercury. The animal was suffered to remain two or three days after he had died, in which time there was no sensible diminution of the air; but on passing lime-water into the jar, the air was diminished  $\frac{1}{5}$ th part of its bulk; and when, in a subsequent experiment, the residual air was agitated in water, it was reduced between one-fifth and one-sixth of the whole. Obs. on Air, vol. v. p. 112, et seq.

Dr. Crawford found, also, that when the experiment was made over mercury, the diminution was not sensible; but that, if water of potash was added to the residual air, it became mild, and the air was diminished in the same degree as if the experiment had been made over water, or nearly one-fifth of its bulk. (On Animal Heat, p. 146.) The variations in these results, compared with those before enumerated, arise, no doubt, from the more or less complete attraction of the carbonic acid by the fluids, over which the experiments were made; and, from the whole of them, we may collect, that when mercury is employed, which has no attraction for carbonic acid, the diminution is

hardly sensible; but that, when this acid is completely abstracted by an alkaline fluid, the loss of bulk amounts nearly to one-fifth of the whole air employed. This inference corresponds very exactly with what occurs in vegetation, and in the respiration of the inferior animals.

In the year 1806, Mr. Dalton's attention was directed to this subject, and he satisfied himself, by numerous experiments, that the bulk of carbonic acid, formed in respiration, was exactly equal to that of the oxygen gas consumed. On repeating these experiments, Dr. Thomson obtained, in some cases, nearly the same results; but, upon the whole, the bulk of oxygen that disappeared was somewhat greater than that of the carbonic acid formed. The difference, however, varied considerably, and kept pace with the diminution in the whole bulk of air; whence he considers it to arise from the abstraction of a part of the air by some other way than by respiration: and if this be allowed for, he believes the bulk of acid produced to be precisely equal to that of oxygen gas lost. Hence, says he, this oxygen must be changed into carbonic acid in the lungs; for oxygen gas, when changed into carbonic acid, does not sensibly alter its bulk. System of Chemistry, 3d edition. vol. v. p. 736, and 774.

These conclusions have been completely confirmed by the very accurate experiments, already noticed, of Allen and Pepys. There was a loss of 23 cubic inches only in 3460 breathed once, at 58 respirations, which occupied 11 minutes. In another experiment, 9890 cubic inches, of which the breathing occupied  $24\frac{1}{2}$  minutes, lost only 18. In subsequent experiments on the respiration of a guinea pig, these chemists found, that when 310 cubic inches of atmospheric air were breathed for 25 minutes by this animal, its volume experienced no variation whatever; and the portion of its oxygen, which disappeared, was replaced by an equal bulk of carbonic acid. These results were particularly satisfactory in their tendency to establish the point, that the air undergoes no diminution; because the time which they occupied was more considerable, and the chance of error, therefore, diminished. The third trial with the guinea pig occupied one hour: the bulk of the atmospheric air, before the experiment, was 1060 cubic inches; after the experiment, 1061; the carbonic acid formed 53 cubic inches; the carbonic acid per minute, .88 of a cubic inch. (Phil. Trans. 1809, p. 414.) Wherefore they justly conclude, that when atmospheric air alone is respired, no other change is produced in it than the substitution of a certain portion of carbonic acid gas for an equal volume of oxygen.

The results of all the trials made by these gentlemen were not uniform, and the deficiency was sometimes greater than what has been stated. The deficiency varied from 4 to 62 cubic inches in ten experiments; in each of which, between 3 and 4000 cubic inches of air were breathed once, the time employed being 10 or 11 minutes in each experiment. They consider that the deficiency principally arises from the last expiration being made into a gasometer, and consequently meeting with more resistance; so that the lungs are less completely evacuated than in the expiration into the open air, with which the experiment commenced.

The difficulty, which these gentlemen allude to, of bringing the lungs to the same state exactly at the end as they were in at the beginning of the experiment, is evinced by the result of their thirteenth trial, which also affords a strong argument against the diminution of bulk, which has hitherto been almost generally assumed as a result of the respiratory process. In  $5\frac{1}{2}$  minutes, 3300 cubic inches were inspired, and 3311 expired; thus exhibiting an increase of 11.

Amid this conflict of authorities, we have no difficulty

in declaring it, as our decided opinion, that the experiments least liable to error, most carefully performed, and therefore deserving our greatest confidence, are those which contradict the notion of an absorption of oxygen.

"In cases," says Mr. Ellis, "where so many causes concur to render the apparent bulk of acid less than it ought to be, and less than that of the oxygen lost, it is surely more reasonable to give greater credit to those results, which indicate an equality of volume between these gases, than to those which declare a difference; since the former not only go with the latter to the fullest extent; but, pursuing the same track, have actually gone beyond them, and thereby reached a point, which the others have been unable to gain. In fact, to prefer those experiments, which indicate a difference, to those which prove an equality of volume, would be not only to halt in our progress, but to make a retrograde movement, and thus to suffer a negative inference to outweigh a positive proof." Further Inquiry, p. 279.

By the experiments of Messrs. Allen and Pepys, we have seen it proved, that when a guinea pig breathes a given quantity of air in a natural manner, no variation whatever was observed in the bulk of that air; and that in man, in whom many causes, not affecting the lower animals, contribute to produce error, when the respiration was nearly natural, the general average of the deficiency, in the total amount of common air inspired, was only about six parts in 1000, and in one instance considerably less than two. The smallness of this deficiency, say these chemists, surprised us very much; and it probably arises from the difficulty, or, as they elsewhere term it, the impossibility of always bringing the lungs to the same state after forcible expiration.

Under other circumstances, as in the experiment recited above, of respiration continued until the operator became insensible, these gentlemen conceive that oxygen is absorbed. To this inference, says Mr. Ellis, as far as it regards what is here called an absorption of oxygen, we must beg leave to object. That the united volumes of oxygen and carbonic acid expired were less than the total volume of oxygen inspired, we readily grant; but we deny that this fact affords any adequate proof of an absorption of this latter gas. To the chemist, indeed, the mere fact of the disappearance of a portion of oxygen may supply sufficient evidence of its absorption, in the sense in which he may choose to employ that term; but the physiologist farther requires to know, by what organs or vessels it is removed, in what course it is conveyed, and what uses it is destined to serve. On none of these points, however, does he gain any information; and all the anatomical knowledge which he possesses of the structure of the lungs, and of the properties of the living absorbent system, is adverse to such a doctrine. Should he apply to the chemist for a solution of his difficulties, he is told that oxygen does not chemically combine with other bodies, unless it be brought into actual contact with them; and he knows, that, in the present case, this contact is impossible, because the membranes, both of the air-cells and blood-vessels, are interposed between the air and the blood in the lungs. Even if, contrary to all experience and analogy, he were to concede to the chemist the existence of pores or other passages in the cells and blood-vessels, through which this oxygen might be attracted and combine with the blood, he is equally embarrassed to discover the reason or mode in which it is again so speedily expelled, or what useful purpose it can serve, since no portion of it is permanently retained. The science of chemistry furnishes no example of similar operations,—of fluids which attract gases and combine them, so as to reduce their elasticity, and then, without any apparent change of condition or circum-

stances, almost instantly discharge them in a new and elastic form.

If, farther, we compare the results of the two series of experiments made by Messrs. Allen and Pepys, the difficulties, in a physiological point of view, greatly accumulate upon us. For, if an absorption of oxygen really take place in the lungs, how does it happen, that, in the first thirteen experiments, made with several thousand cubic inches of air, and which occupied from ten to twenty-four minutes of time, a very small loss in the whole bulk of air, and not the smallest in its proportion of oxygen, occurred; while, in two other experiments, made with only 300 inches of air, and continued only for three minutes of time, a great deficiency in the whole bulk of air, and a loss of one-third of its oxygen, took place. In all these experiments, except the twelfth, in which, instead of loss, there was actually an increase of eleven cubic inches upon the bulk of air respired (Phil. Trans. 1808, p. 256.), the same person appears to have breathed, and the air was of similar composition. Consequently, the cause of variation in the result is to be sought, not in any difference in the animal organs, or in the original composition of the air, but, probably, in some circumstances of dissimilarity, which accompanied the progress of the experiment.

Now the bare statement of facts points out a great dissimilarity, not only in the chemical results, but in the circumstances accompanying the experiments, and in the effects which they produced in the system. For in the first thirteen experiments, which occupied from ten to twenty-four minutes, and in which no loss of oxygen occurred, the air was only once passed through the lungs, the breathing was nearly natural, the operator scarcely fatigued, and his pulse not raised more than about one beat in a minute. (Ibid. 253.) But in the two experiments in which oxygen is said to be absorbed, the same air was passed eight or ten times through the lungs; and, in less than a minute, the operator found himself obliged to take deeper and deeper inspirations. At last, the efforts to take in air became very strong and sudden, with a great sense of oppression and suffocation in the chest, indistinct vision, buzz in the ears, loss of recollection, and, at the end of three minutes, perfect insensibility. (Ibid. 260—262.) This difference in the effects produced in the system, we do not hesitate to ascribe to a difference in the composition of the air, which, in the first experiments, was respired in a natural state, but, in the two last, by repeated breathing, was rendered more and more unfit to carry on respiration, until, at length, its power of supporting that function altogether ceased.

But because under circumstances, in which the mental and animal powers were in complete abeyance, the respiratory organs were not able to make so complete an expulsion of the inspired air as they effect in their natural state of health and vigour, are we, therefore, entitled at once to conclude, that all the air which was not expelled was really absorbed? Setting aside the anatomical difficulties in the case, let us, for a moment, look only to the chemical consequences, to which such a conclusion would conduct us. If the mere disappearance of any gas, received into the lungs, be sufficient evidence of its absorption, then every gas, which is not returned, must be held to be absorbed. Are we then prepared to admit that hydrogen and nitrogen gases are absorbed by the blood? for, when their respiration is carried to its full extent, they, too, equally disappear. This supposed absorption, however, cannot proceed from the operation of chemical attraction, for little or no affinity subsists between these gases and the blood. Neither can it arise from the operation of the living system; for it occurs only

## RESPIRATION.

when the living powers are about to cease. To us there appears but one way of escaping from these manifold difficulties, which is simply to conclude, that the inspired air, which is not returned, is retained in the cells of the lungs. Such a supposition dissipates at once all anatomical and chemical difficulties, and explains why no air disappears in natural respiration, when the expiratory powers are in full vigour and able to expel it, and why its disappearance increases in proportion as the actions of these powers decline and cease.

It is, however, worthy of remark, that, in these last experiments, not only was there a diminution in the whole bulk of air, but its relative proportions likewise varied; for, in 100 parts, the oxygen and carbonic acid amounted together only to about two-thirds of the usual quantity of oxygen, and the deficiency was supplied by a superabundance of nitrogen gas. We are not prepared to say why, in this very embarrassed state of the respiratory function, the relative proportions of the expired air should thus vary; but the fact proves only the retention of oxygen in the lungs, but not its absorption by the blood. Should it even be maintained that oxygen was absorbed, because, in these two experiments, a portion of it disappeared, then, by the same mode of reasoning, we must also contend, that, in the thirteen preceding experiments, no absorption of oxygen took place, because no part of it was retained; and as these last experiments alone come near to the natural exercise of this function, they authorize us to conclude, that such supposed absorption of oxygen constitutes no necessary part of healthy respiration. In truth, in some instances where a mixture of oxygen and hydrogen gases was respired, the oxygen and carbonic acid in the expired air uniformly exceeded, by one *per cent.* the total oxygen inspired (Phil. Transf. 1809, p. 425.); from which it may be inferred, that these variations in the proportions of the expired air proceed entirely from accidental causes, and are totally independent of any absorbent function in the lungs. Further Inquiry, v. 2. ch. 4.

If we are correct in representing that the air undergoes no diminution of volume in breathing, it will follow necessarily that no part of it can be absorbed in the lungs. This notion of absorption is not only at variance with the results of the most accurate direct experiments, but it is also repugnant to our knowledge of the structure of the lungs. The fineness of the absorbing vessels, the mucus perpetually smeared the surface of the cells, the elastic nature of air itself, so that it neither penetrates moist paper, cloth, nor skin—all demonstrate that no air gets into the blood by this route. If, indeed, air were taken up by the absorbents, it must pass to the right side of the heart, and change the colour of the blood there, which does not happen.]

But if, either by the function of absorption, or by the operation of chemical affinity, air did enter into the blood, we may surely with reason demand some proof of its presence; yet, says Haller, “Nulla unquam in vivo calido animali bulla aëris in sanguine visa est.” (Primæ Lin. f. 306.) This opinion is confirmed by the direct experiments of Dr. Darwin; for having inclosed a portion of the jugular vein of a sheep between two ligatures, it was cut out, stripped of its adhering cellular membrane, and then thrown into a glass of water of temperature 100°, standing under the receiver of an air-pump. It at once sunk to the bottom, and did not rise when the air was exhausted; nor, when afterwards taken out, wiped dry, and laid on the floor of the receiver, did it exhibit any swelling under the exhaustion of the vessel. The experiment was repeated with a similar re-

sult on a portion of the vena cava of a pig. Phil. Transf. v. lxiv. p. 345.

Neither do the effects resulting from the admixture of æriform fluids with the blood, favour the notion of the entrance of air into that fluid. “Animal, cui aër in sanguinem inflatur,” says Haller, “perit certo et velociter; neque quidquam fati certi est in sanguinis vesarum pulmonalium aucto rubore.” (Loc. cit.) This assertion is confirmed likewise by direct experiment. When Dr. Girtanner injected oxygen gas into the jugular vein of a dog, he cried dreadfully, breathed quick, and died in three minutes; when nitrogen gas was thrown in, death happened in 20 seconds. (Memoirs on Irritability, pp. 221. 223.) Air, says Bichat, thrown into the vascular system, quickly brings on agitation, convulsions, and death. (Récherches sur la Vie et la Mort, p. 179.) By forcing air through the wind-pipe into the lungs with a syringe, and confining it there, he has made it to enter into the blood-vessels, which immediately brings on agitation and exertion in the animal; and if an artery in the leg or foot be now opened, the blood will spring out frothy, and full of bubbles of air. If hydrogen gas has been used, the bubbles may be inflamed; and when this frothy blood has flowed 30 seconds, the actions of life cease, and cannot again be restored, even although fresh air be supplied. Ibid. 303. Inquiry, § 102, 103.

If, then, no proof exist of the passage of air into the blood by the ordinary course of the absorbent vessels, the only other mode of effecting this purpose that has been hitherto suggested, is the power of *chemical affinity*. What then are the chemical affinities subsisting between venal blood and atmospheric air? About the middle of the 17th century, Dr. Lower observed, that the upper surface of venal blood, received into a vessel, acquired a scarlet colour by exposure to the air; that if this surface was removed, the subjacent one was soon changed to the same colour; that if the cake of blood, after being allowed to settle in the vessel, was inverted, its exterior and upper surface speedily also assumed a florid hue; and, lastly, that if venal blood was shaken in a vessel, so that the air thoroughly intermixed with it, it became entirely florid. (De Corde, p. 178.) These opinions were afterwards held by Sig. Fracassati and Dr. Slare, the latter of whom observes, that the blood thrown up by a rupture of the capillary vessels of the lungs, is frothy and of a scarlet colour; the first of which effects he attributes to the intermixture of air, and the latter to its tinging power. (Lowthorpe’s Abridg. Phil. Transf. v. iii. p. 235.) Mr. Hewson employed similar arguments to prove, that the florid colour, acquired by venal blood on exposure, was produced by the contact of the air; and, by injecting air into the jugular vein of a rabbit, he found that it there also rendered the blood florid. (Hewson on the Blood, p. 9.) M. Cigna not only confirmed the foregoing facts, but proved also that the change of colour in this fluid did not take place when the blood was covered with oil or placed *in vacuo*; and Dr. Priestley ascertained that not only by common air, but more especially by oxygen gas, this florid colour was produced on the black crassamentum of blood. On Air, v. iii. p. 66.

In effecting these remarkable alterations in the colour of the blood, the air itself, at the same time, suffers material changes. Dr. Priestley found, that in twenty-four hours oxygen gas was so far depraved by being in contact with venal blood, that one measure of it and two of nitrous gas occupied the space of a measure and a half, whereas, at the beginning of the experiment, they occupied the space of no more than half a measure. (Loc. cit. p. 55.) Dr. Good-

## RESPIRATION.

wyn confined venal blood under a jar of oxygen gas inverted in mercury, and repeatedly observed that the change of colour was always very sudden, and, after several minutes, the mercury ascended two or three lines; from which he concluded that a small portion of the air had disappeared. (Essay, p. 61.) The precise change, however, which the air underwent, seems first to have been observed by Dr. Girtanner, who placed six ounces of venal blood in a jar of oxygen gas inverted in mercury; the blood presently assumed a florid colour; the air was somewhat diminished in bulk, and contained a portion of carbonic acid, which was attracted by lime-water. (Beddoes' Obs. on Calculus, &c. p. 219.) Dr. Bostock observes also, that a diminution of oxygen and production of carbonic acid take place when a piece of crassamentum is placed in a jar filled with oxygen gas. (On Respiration, p. 227.) The same production of carbonic acid occurs when blood is placed in contact with atmospheric air. A quantity of this fluid was received into a cup, and confined in a jar of air inverted in water, a glass of lime-water having been previously placed in the cup. The internal surface of the jar was soon bedewed with moisture, and a pellicle began to form on the lime-water, which, in a few hours, was increased to a thick crust of carbonate of lime. The crassamentum was then removed, and a fresh glass of lime-water was placed in the serum, which, in thirty-six hours, had acquired a crust like the former, and the water had risen considerably into the jar. In another experiment, where the serum was placed for twenty-four hours in a jar of air inverted in mercury, the residual air rendered lime-water milky, and the remainder had lost a part of its oxygen. A similar production of carbonic acid seems to have occurred, when, with a small diminution of the gas, a slight change of colour was produced on venal blood by placing it in contact with nitrous oxyd, in the experiments of Mr. Davy; for when a solution of strontian was admitted to the oxyd, it became slightly clouded, and, with the diminution of bulk that followed, minute portions of carbonic acid and nitrogen gas were produced. (Researches, pp. 377. 380. 387.) Hence then we learn, that when venal blood is exposed to the contact of atmospheric air, of oxygen gas, or of nitrous oxyd, it presently assumes a florid colour, and, at the same time, the volume of air is somewhat diminished, and a portion of carbonic acid is produced.

Does then the carbonic acid, which is here met with, proceed ready formed from the blood, or is it in part formed by the decomposition of the air? No one has yet proved that any æriform fluid, much less that carbonic acid, exists naturally in the blood; and if this be true, no such ærial acid can be expected to issue from it. The carbonic acid also, is not formed by blood when it is confined in nitrogen gas; neither does the colour of the blood, in that case, undergo any sensible change; but this acid is formed by blood, either in oxygen gas, in nitrous oxyd, or in atmospheric air, all of which are deteriorated thereby; whence it follows, that without the presence of oxygen gas, the blood is unable to form carbonic acid, and that this acid, therefore, is, in part, formed out of that gas. If the oxygen gas that disappears do not contribute to form the carbonic acid that is produced, in what other manner can its loss be accounted for? or from what other source than the oxygen gas of the air, in contact with the blood, can that ingredient of the acid be derived? Those who suppose the carbonic acid to be furnished by the blood, independent of the air employed, must likewise suppose that the nitrogen gas is furnished by it also; for the experiments of Mr. Davy

teach us, that a portion of that gas, as well as of carbonic acid, is always present when nitrous oxyd is decomposed, which renders it probable that the same thing likewise occurs when air is changed by venal blood. But in what manner the blood should be able to furnish nitrogen gas, it is not easy to conceive, since no affinity exists between that gas and venal blood. (Davy's Researches, p. 375.) We infer, therefore, from these facts, that atmospheric air is decomposed by being placed in contact with venal blood, its oxygenous portion being in part converted into carbonic acid, and a quantity of its nitrogen being, in consequence, left free.

But, supposing the air to be thus decomposed by the blood, it still remains a question, whether it has been first attracted by that fluid, then decomposed, and afterwards in part expelled; or, whether the decomposition has been effected without such previous attraction and intermixture of air. The only evidence of this supposed attraction seems to be the small diminution of bulk, which the air in all cases suffers; but this cannot be considered as a proof of the attraction of the air; for it is a necessary consequence of that conversion of oxygen gas into carbonic acid, which has been shewn to take place, when these substances are brought into contact. Even granting to the blood this power of attracting air, or its oxygenous portion, it is not easy to conceive, why it should so readily lose it, and again give out this air in the form of carbonic acid. No change of quality in the blood, nor any variation of temperature, can have taken place sufficient to alter so rapidly its affinity for these substances: and it cannot proceed from a want of affinity between the blood and the carbonic acid that is formed; for that acid suffers a greater diminution, either than oxygen gas or atmospheric air, by being placed in contact with blood. We incline, therefore, to the opinion, that neither the air nor its oxygen gas is attracted by, and diffused through the blood, as happens with several gases when placed in contact with certain fluids: but that the air is decomposed, and its oxygen gas changed into carbonic acid, without entering into the substance of that fluid.

But, for the formation of this acid, the blood must supply carbon, since no other substance was present from which it could be derived: and it is well known also, that carbon enters largely into the composition of that fluid; and our experiments prove, that it exists as well in the ferrous as in the more solid parts. By some it may be objected, that because carbonic acid is formed directly by the combustion of charcoal, it cannot be produced at so low a temperature as exists in these experiments. To this we can reply only by an appeal to the general facts exhibited through the whole course of our enquiry, by which it appears, that both by the living functions of vegetables and animals, and by the decomposition of animal and vegetable matter, this acid is in like manner formed at temperatures equally low. Even those, who consider this acid to have proceeded ready formed from the blood, cannot attribute its production to the operation of heat; for in the animal body, the temperature of the blood seldom exceeds 100°—a degree of heat incompetent to form carbonic acid by any process analogous to combustion. The combination of many bodies is, indeed, greatly accelerated by being exposed to very high temperatures; but this surely does not set aside the fact of their spontaneous union at temperatures much more low. From this review of the effects, which take place between the blood and air, we conclude, that the chemical phenomena, which arise when the substances

## RESPIRATION.

are placed in contact, do not prove an attraction and diffusion of air through the blood; but shew only that a reciprocal action takes place, by which a new product is formed: no inference, therefore, in favour of an attraction of air by the blood in the lungs, can be drawn from the reciprocal action which they exert on each other out of the body. Inquiry, § 96—100.

It is, farther, an objection to this supposed operation of oxygen, that in the lungs the blood and air do not come into contact, and therefore although the combination of oxygen with that fluid might be conceived to happen, when they are placed together out of the body, yet the intervention of organised membranes may be supposed to prevent such an union in the living system. In the ordinary operations of chemistry, such an interposition of animal substance would be considered sufficient to vitiate the result of any similar experiment in which it was employed; but in the application of this science to the living body, neither membranes nor blood-vessels are conceived to oppose any obstacle to the exertion of chemical action, or, in the smallest degree, to affect its result. In support of this supposed operation of oxygen on the blood, some experiments of Dr. Priestley have been appealed to, as affording decisive evidence that this substance has the power of penetrating a compact membranous body, and may, consequently, penetrate the cells and blood-vessels of the lungs. The importance, which has been attached to these experiments, in all the late hypotheses which have been proposed to explain the function of respiration, renders it necessary for us to examine them with some minuteness, in order to discover the true relation which they bear to the present question.

Dr. Priestley, who, as we shall hereafter see, supposed that venal blood became red by imparting its phlogiston to the air, knew well that the blood in the lungs was separated from the air by a membranous substance, which, however, according to Dr. Hales, does not in thickness exceed the  $\frac{1}{1000}$ th part of an inch. To ascertain the effect of this circumstance, he put some black blood into a bladder moistened with a little serum, and then tying the bladder very close, he hung it in a free exposure to the air. The next day, all the lower surface of the blood, which had been separated from the air by the intervention of the bladder, had acquired a coating of a florid red colour, as thick, it appeared, as it would have acquired, if it had been immediately exposed to the open air; so that this membrane had been no impediment to the action of the air on the blood. This experiment was repeated, without previously moistening the bladder, and with the very same result. *Obs. on Air*, vol. iii. p. 369.

But although in these experiments the blood was rendered red by the agency of the air, yet we are not entitled to conclude, that this redness was produced by the combination of its oxygen, unless we can shew, not only that this substance comes into contact with the blood, but is likewise capable of changing it to a red colour. Dr. Priestley himself, who believed the blood to become red by the loss of phlogiston, could draw no such conclusion; and it is not a little remarkable that this philosopher, who had before so well observed the reciprocal effects produced in the air, when it thus changed the colour of the blood (*loc. cit.* p. 336.), should in these experiments have entirely overlooked them. It is still more remarkable, since these experiments have drawn so much attention, and seem now to be the chief or only remaining evidence urged in support of the hypothesis of oxygenation, that some attempt has not been made to inquire farther into the actual circum-

stances which attend them. It is this examination which we now propose to make, in the hope, that if it do not lead us to a knowledge of the true cause of this phenomenon, it may at least serve to shew to what it is not to be ascribed.

With this view, we procured a quantity of black blood, and putting it into a sheep's bladder, suspended it from the top of a jar containing about 100 cubic inches of atmospheric air. The jar was inverted in a saucer containing mercury, and within it a small cup of solution of potassa was likewise placed. The blood, in a short time, assumed a florid hue, and a dimness extended over the inside of the jar. By the next day, the mercury in the saucer had risen  $\frac{7}{8}$ ths of an inch into the jar, and it continued to rise several days; so that by the fifth day it had reached nearly to an inch in height. The jar was then raised, and diluted acid being poured upon the alkaline solution, disengaged from it a large quantity of carbonic acid gas. By this experiment, therefore, we are taught, that, when black blood allumes a red colour by being thus placed in a moistened bladder, and exposed to atmospheric air, the air itself, at the same time, undergoes a change; for its volume is diminished, and carbonic acid is produced.

To ascertain these facts with greater precision, we put another quantity of black blood into a small bladder, and suspended it, as before, from the top of a small jar inverted in mercury, and which contained 18.3 cubic inches of atmospheric air. Under this jar also a small cup of solution of potassa was placed. The blood, as before, was soon reddened, and the jar became dim. In two days, the mercury had risen nearly half an inch into the jar, and by the close of the fourth day, it stood seven-eighths of an inch high, where it remained for some time quite stationary. On analysing the residual air, it was found to suffer no change, either from agitation with lime-water, or by being exposed to the contact of phosphorus; so that, though all the oxygen had disappeared, no carbonic acid was present, but that gas was entirely attracted by the water of potassa employed.

The capacity of the jar, in the above experiment, has been stated to be equal to 18.3 cubic inches; and the bladder, with its contents, together with the cup and solution, we found to occupy a space equal to 5.2, which reduces the actual bulk of air, employed in the experiment, to 13.1 cubic inches. The mercury which in consequence of the attraction of the carbonic acid had risen seven-eighths of an inch into the jar, occupied a space equal to three cubic inches; so that of the 13.1 inches of air originally employed, three had disappeared, and  $\frac{10}{13}$ ths =  $\frac{10}{13}$ ths, or a portion of the air, was thus converted into carbonic acid, which comes very near to the proportion of oxygen gas which the atmosphere is known to contain. Hence we infer, that, in this experiment, all the oxygen gas that disappeared was converted into carbonic acid; and consequently we deny that any oxygen penetrated the bladder, in order to combine with the blood.

As thus it is denied that the blood, in these experiments, received any ponderable matter from the air, so likewise it will appear, from the facts which follow, that the air receives no such matter from the blood. We filled bladders with water, and suspended them in jars of atmospheric air, in the manner described above; and found that the oxygen gas of this air was converted into carbonic acid, in the same manner as when the bladders were filled with blood; and if the experiment was continued a sufficient length of time, the whole of the oxygen gas was, in like manner, made to disappear. The same effects followed from the introduction

## RESPIRATION.

of moistened empty bladders; and, indeed, it is the usual effect produced in the air by every moistened animal substance. If, therefore, the moistened bladder be thus capable, by itself, of acting on the air, we are entitled to conclude that it exerts the same action when it is filled with blood; and as, on this supposition, the oxygen gas will unite with the carbon, furnished directly by the bladder, we have no ground whatever to suppose this carbon to come from the blood. Hence, therefore, when black blood is reddened by the air, through the coats of a moistened bladder, the air yields no oxygen to the blood, nor acquires from it any carbon; but the carbon of the bladder, by its combination with the oxygen of the air, passes into a state of carbonic acid gas. Further Inquiry, § 581—587.

That this change in the colour of blood is always accompanied by a corresponding change in the air, may be farther inferred from other experiments of Dr. Priestley. He found that, when the black crassamentum of blood was covered by serum or milk, it nevertheless acquired a florid hue, on being exposed to the air (*Obs. on Air*, vol. iii. p. 370.); and Dr. Wells observed, that a covering of albumen, also, did not prevent the action of the air on the blood. (*Phil. Transf.* 1797.) Now we know that serum and albumen convert the oxygen gas of the air into carbonic acid; and we found by experiment, that the same effect was produced by milk, as probably would be the case with most of the animal fluids. Hence it is evident, that when the blood, in the experiments of Dr. Priestley, became florid, through several inches of serum, the oxygen gas must have been at once changed by it into carbonic acid, and could never, therefore, in the form of oxygen, be conveyed through this fluid to act on the blood.

On the other hand, Dr. Priestley found a thin stratum of water to prevent entirely this action of air on the blood. (*Obs. on Air*, vol. iii. p. 370.) M. Cigna found the same thing to take place, when a pellicle of oil was interposed (*ibid.*); and Dr. Wells ascribes a similar effect to a solution of gum arabic. These substances, however, act little, if at all, in changing the air; and no change of colour, therefore, takes place in the blood. That black blood should have the power of attracting the oxygen of the air, through several inches of serum, and yet lose this power when a thin stratum of water is interposed, seems somewhat surprising, if the intervening fluid be, in each case, considered to be equally passive; but proceeding on the fact, that the serum exerts an action on the air, which the water is incapable of effecting, a new circumstance comes into view, and upon it the colouration of the blood may probably depend.

If, then, it appear, that the interposition of substances between the blood and the air necessarily prevents that contact, which is essential to the chemical union of oxygen with that fluid; if it also appear, that the colour of the blood is never, in such cases, changed, unless such substances be interposed, as are themselves capable of acting on the air; and if, lastly, it be proved, that when the blood exhibits this change of colour, the air suffers a change, and that its oxygen, instead of combining with the blood, is really contained in the carbonic acid that is formed, we must conclude, that, whatever be the mode in which the air contributes to change the colour of the blood, it cannot be by imparting to it any portion of its ponderable matter. Consequently, although these facts prove that oxygen gas possesses the power of changing the colour of the blood, as well through dead as through living animal membranes, yet they afford no evidence of the combination of oxygen with that fluid, but shew only the conversion of that gas into carbonic

acid, precisely in the same manner as this acid gas is formed, when the blood is reddened in the ordinary process of respiration.

Even when the air and blood are brought into contact, they only exert a reciprocal action on each other, by which carbonic acid is formed, but no oxygen appears to combine with the blood. We have already given various proofs, that, when the blood is changed in colour by the agency of the air, the oxygen gas of the air disappears, and carbonic acid is produced. These facts are confirmed by the experiments of M. Berthollet, who confined recent blood in a vessel of common air, and, at the end of twenty-four hours, the air, on analysis, afforded nearly  $\frac{1}{10}$  of carbonic acid. In two other experiments, similar results were afforded; and in all these experiments, the acid gas produced was exactly equal to the volume of oxygen that disappeared. (*Mem. d'Arcueil*, tom. ii. p. 462.) Unless, therefore, it be maintained, that the same oxygen can, at the same time, exist in two combinations, we must suppose, that, in these experiments, no oxygen combines with the blood; and from whatever cause, therefore, the red colour of the blood may proceed, we may safely conclude that it cannot arise from the combination of oxygen. Further Inquiry, § 592—595.

Mr. Ellis considers that the diminution in bulk, which the respired air undergoes, according to the results of most investigations, may be accounted for by the condensation which oxygen experiences in uniting with charcoal to form carbonic acid. Crawford estimated this diminution at  $\frac{1}{7}$ th, Lavoisier at  $\frac{1}{7}$ th. But the experiments of Allen and Pepys (*Phil. Transf.* 1807), performed with a very perfect apparatus, and therefore apparently deserving confidence, do not support this notion of condensation. When they transmitted repeatedly oxygen gas over ignited charcoal, so as to convert it into carbonic acid, the volume was the same at the end of the experiment as at the commencement. The researches of these chemists on respiration, published since the appearance of the "Inquiry," making it very probable that there is no loss of bulk in the air respired, coincides with what they have proved concerning the constitution of carbonic acid.

*Whether the azote of the inspired air undergoes any change?*—Mr. Murray has brought together all that is known on this point, and arranged it so clearly, that we avail ourselves of his labours, without any further remark.

"It is lastly to be determined, what is the influence of the nitrogen of the atmosphere in respiration; and with regard to this, different conclusions have been formed. Lavoisier, in his early experiments, considered the nitrogen of the atmospheric air as suffering no change in respiration. *Mem. de l'Acad. des Sciences*, 1777. *Mémoires de la Société de Médecine*, 1783.

Priestley, in the experiments already referred to, in which he breathed the same air repeatedly, observed an apparent consumption of its nitrogen, as well as of its oxygen; but he afterwards inclined to the supposition, that the deficiency of nitrogen arose from the greater proportion of it in the lungs after the process than before.

Mr. Davy investigated this, and concluded that nitrogen is consumed in respiration; a quantity disappearing equal to about two-tenths of a cubic inch at each natural respiration, 13 cubic inches being the quantity of air taken into the lungs. As the number of natural inspirations amounted in a minute to 26 or 27, it followed that, in this time, 5.2 cubic inches of nitrogen are consumed; a result which was confirmed by continued respiration, as well as by the respiration of animals confined in a portion of air; though,

## RESPIRATION.

though, in the latter case, the quantity consumed appeared to be less. *Chemical Researches*, p. 434.

This absorption of nitrogen in respiration appeared to be confirmed by other experiments. It was observed by Dr. Henderfon, in breathing a portion of air repeatedly from and into a gasometer. (*Nicholson's Journal*, vol. viii. p. 40.) And it seemed likewise to be established by the experiments of Pfaff. *Nicholson's Journal*, vol. xii. p. 249.

These experiments, however, are not free from fallacy, particularly those where the same quantity of air was repeatedly breathed; for, as Mr. Ellis has justly observed, (*Inquiry on Vegetation, Respiration, &c.* p. 114.) the respiration, as it proceeds, becomes more difficult and laborious, and is at length terminated by a feeble expiration, in consequence of which the due proportion of air is not thrown from the lungs. There appears, therefore, a diminution; and accordingly it is stated by Pfaff, that the diminution and the loss of nitrogen is always the greater, the longer the air is respired. There can be little doubt that the apparent diminution arises from this cause; and accordingly, in the experiments of Allen and Pepys, in which this source of error is avoided, there is no apparent consumption of nitrogen. The same result is stated to have been obtained in the last experiments of Lavoisier and Seguin, "there being neither any disengagement nor absorption of nitrogen gas during the respiration." (*Mem. de l'Acad. des Sciences*, 1789, p. 374.) From the experiments of Vauquelin, Spallanzani, and Ellis (*Inquiry, &c.* p. 87, 88.), it also appears that there is no sensible consumption of nitrogen, by the respiration of the lower orders of animals, while there is the usual consumption of oxygen, and formation of carbonic acid.

Messrs. Allen and Pepys, from some experiments (*Phil. Transf.* 1809), inferred, that there is even an evolution of nitrogen in respiration. They observed this, first, in the respiration of oxygen gas; in one experiment, where 3000 cubic inches of oxygen had passed through the lungs, 62 cubic inches of nitrogen being found in the first 260 cubic inches expired, though the gas originally contained only six cubic inches in this quantity; and in the next 562 cubic inches, 56 cubic inches were found, though this quantity, before it was respired, contained only 14; and a similar evo-

lution of nitrogen was observed in the repeated respiration of the same quantity of oxygen, an equivalent quantity of oxygen disappearing. Much of this loss of nitrogen may, as they observe, be ascribed to the intermixture of the residual air in the lungs; but from comparing the capacity of the lungs with the quantity of nitrogen evolved, they found more of it to be evolved than could be derived from this source; and were therefore led to the conclusion, that where oxygen gas is respired, a portion of nitrogen is given off from the blood. This conclusion appeared to be confirmed by the results of experiments on a guinea pig, confined in a quantity of atmospheric air. In one experiment, at the end of an hour and twelve minutes, the increase of nitrogen in the air was more than equal to the cubic contents of the body of the animal. In the respiration of a mixture of oxygen and nitrogen gases, a similar evolution of nitrogen, and disappearance of an equivalent portion of oxygen, was observed; but not in the respiration of atmospheric air.

Three thousand four hundred and twenty cubic inches of air, consisting of 2.5 azote, and 97.5 oxygen in 100 parts, were breathed for 7' 25": the expired air measured 3362, therefore the deficiency was 58. The expired air was received in 13 successive portions; of which N<sup>o</sup> 1. contained, in 100 parts, 9 carbonic acid, 25 azote, 66 oxygen. N<sup>o</sup> 13. consisted of 12.5 carbonic acid, 5.5 azote, and 82 oxygen, in 100 parts. When all the thirteen were mixed, the composition was 12.0 carbonic acid, 6.5 azote, 81.5 oxygen. The whole quantity of carbonic acid formed in this experiment was 396.78 cubic inches. The quantity of azote taken into the lungs was 85.50; the quantity expired, 263.10: the increase is, therefore, 177.60. (*Phil. Transf.* 1808.) In another experiment of a similar nature, 2668 of gas were breathed backwards and forwards for 13 minutes; it contained 4 per cent. of azote. There was a deficiency of 124 cubic inches in the expired air, the largest ever observed by these gentlemen. In this experiment there was an increase of 105.08 of azote. If the azote emitted from the lungs in these experiments be supposed to have been contained in those organs before the experiments began, it will make their contents more considerable than we had before calculated. The following is a summary of four experiments on this subject:

	Barom.	Therm.	Oxygen gas, &c. inspired.	Gas expired.	Deficiency.	Time.	Quantity respired in a Minute.	Azote evolved.	Inferred capacity of Lungs.
N <sup>o</sup> 1.	—	53°	3260	3193	67	9' 20"	348	110	141
2.	30.3	70	3420	3362	58	7 25	461	177	225
3.	30.15	70	3130	3060	70	8 45	357	187	236
4.	29.4	51	2668	2544	124	13 0	205	105	133

The particulars of two analogous experiments on the guinea pig follow:

	Barom.	Therm.	Oxygen, &c. inspired.	Gas after the Exp.	Deficiency.	Carb. acid formed.	Carb. acid per Minute.	Time.	Oxygen missing.	Azote added.

*Philos. Transf.* 1808 and 1809.

The conclusion that the nitrogen, found in these cases, is derived from the residual air of the lungs, is so probable, that it would at once be admitted, were it not that the quantity evolved is so large, as apparently to preclude its admission. Mr. Ellis, however, in some very ingenious observations on this question, has pointed out a source of fallacy to which there is every probability that the result is to be ascribed. It is, that the air in the lungs may be

in a condensed state, or occupy less volume than it would do when it is expired; and hence, in the respiration of oxygen, a larger portion of nitrogen derived from the residual air in the lungs may be given out than could be inferred from their known capacity. The structure of the lungs is cellular, and the air is diffused in cells of an immense number, and at the same time of diameters extremely small. If these cells have any degree of contractile power, this may produce

## RESPIRATION.

duce condensation of the air they contain. But independent of this, it is well known, as Mr. Ellis remarks, that a strong attraction or adhesion is exerted between air and the surfaces of all bodies; the more, therefore, the surface is increased, the greater must be the effect from this attractive force. Hence, under the extensive surface of the cells of the lungs, it must operate with great effect, and reduce considerably the volume of the air. The absorption of aerial fluids by charcoal, Mr. Ellis adduces as illustrating this operation of adhesion; and in the lungs it is sufficiently probable, that it may be aided by the affinity exerted by the humid surface to the aerial matter.

All the phenomena accord much better with this view than with the conclusion that nitrogen is evolved from the blood. Thus the "production of nitrogen is always greatest in the first expiration, and its quantity progressively diminishes, until towards the close of the experiment, it is reduced almost to nothing, circumstances which seem plainly to shew that nitrogen is no longer obtained when all the residual air in the lungs is removed. If this nitrogen were furnished by the blood independent of the residual air, no reason occurs why it should thus diminish, and cease to appear, as this air is abstracted; for the function of respiration goes on, and the blood, as far as depends on itself, cannot be considered less fit to supply nitrogen. The fact, also, that no such excess of nitrogen is furnished in natural respiration, militates against the notion of its proceeding from the blood. No excess of nitrogen, too, is ever afforded in other cases, unless its place be supplied by an equal or superior bulk of some other gas. And this affords evidence, that in this supposed evolution of nitrogen from the blood, nothing more than a mechanical substitution of one gas for another takes place." (Farther Inquiries, &c. p. 306.) Murray's System of Chemistry, 3d edit. v. 4. p. 498, et seq.

Adopting, as we do entirely, the views of Mr. Ellis on the subject of respiration (to whose clear, logical, and very satisfactory works we refer our readers for more ample information), we conclude our review of the changes, which the atmosphere undergoes in respiration, in the words of his "Further Inquiry," § 621.

"From the foregoing series of facts, concerning the respiration of the higher classes of animals, we feel ourselves entitled to repeat with increased confidence, that 'the whole of the oxygen gas which disappears in respiration is employed to form the carbonic acid produced in that process.' And that 'the nitrogen gas of the air neither suffers any change itself, nor produces any direct operation on the animal system.' Or, in the words of Messrs. Allen and Pepys, 'When atmospheric air alone is respired, no other change takes place in it, than the substitution of a certain portion of carbonic acid gas for an equal volume of oxygen.' (Phil. Transf. 1809, p. 427.) Consequently in man, as well as in the lower animals, the conversion of oxygen gas into carbonic acid constitutes the only essential change, which the air of our atmosphere experiences in the lungs during its respiration."

*Aqueous Vapour contained in the expired Air.*—That the air expelled from the lungs contains a certain quantity of watery vapour, is rendered very obvious by its condensation, when we breathe cold air. It is not very easy to ascertain its quantity.

Dr. Hales performed many experiments for this purpose: he contrived to pass the air which he expired through a flask filled with woodashes, which, in consequence of the potash contained in them, have the property of strongly attracting the moisture. By observing the increase of weight

which the acid had acquired in a given time, he estimates that the water emitted from the lungs in 24 hours, will amount to 9792 grains, above 20 ounces. (Statistical Essays, v. 2. p. 322—4.) The nature of his process, however, did not admit of much accuracy. Dr. Menzies attempted to solve this problem, by actually collecting in an allantoid fitted to the mouth, the water emitted from the lungs in a given time; his estimate is much less than that of Hales; he supposed that the quantity of water exhaled in 24 hours would amount to no more than 6 ounces, or 2880 grains. (Dissertation on Respiration, p. 54.) Mr. Abernethy, by breathing into a glass vessel of a peculiar construction, collected in an hour 180 grains of water, containing, as he supposed, a quantity of mucous matter. According to his estimate, the quantity emitted in 24 hours, would amount to exactly 9 ounces, or 4320 grains, but as the substance which he obtained was not pure water, there must be some deduction made from it on this account. We are not informed what proportion the water bore to the mucus dissolved in it. Surgical Essays, pt. 1. 141.

The difficulty of actually collecting and weighing the pulmonary exhalation, is probably the cause which induced Lavoisier in his experiments upon respiration, to ascertain its quantity by a calculation, founded upon the proportion between its constituent parts, compared with the composition of the other substances which are received into and discharged from the lungs. He first determined by direct experiment the quantity of oxygen consumed, and of carbonic acid produced; the composition of carbonic acid is known, and by comparing the oxygen which had disappeared with the quantity which would have been necessary to form the acid, he found that the oxygen consumed was more than sufficient to compose the carbonic acid which was actually produced. He supposed that this superabundant quantity of oxygen was employed in the formation of water, by uniting in the lungs with a portion of hydrogen: he estimates the amount of the water by knowing what quantity of it a given weight of oxygen can produce.

In the first memoir (1789), the quantity of water emitted from the lungs of a man in 24 hours, is stated to be no more than 337.18 grains. In the 2d (1790), this quantity is raised to 11180.57 grains, or nearly 2 lbs. troy: and in the last experiments recorded by La Place, the quantity is still more considerable, viz. 13704 grains. The proportion between the water and the carbonic acid is very various in these different researches: in the first they are respectively 337.18 grains, and 17720.89 grains, or as 19 to 1000 nearly: in the second, 11188.57 and 8450.24, or as 1323 to 1000; and in the third, 13704 and 7550.40, or as 1815 to 1000. Such discordant results can have no other effect than that of diminishing our confidence in the whole of them.

Mr. Murray breathed into a bladder containing acetate of potash, a very deliquescent salt, and calculated the quantity of vapour expired by the increase of weight in the bladder and its contents, after the expired air had cooled. In this way he inferred that three grains of watery vapour are expelled from the lungs in a minute. Syst. of Chemistry, v. 4. p. 497.

There are two ways of explaining the production of the watery vapour expelled from the lungs: by evaporation of the mucous fluid covering the inner surface of the air-tubes and vesicles by the constant passage of the air to and from these parts, which are kept at a temperature of about 98°; or by exhalation from the pulmonary or bronchial blood-vessels. The secretion of the mucous membrane of the lungs must undergo evaporation, under the circumstances of

## RESPIRATION.

its exposure to the atmospheric current in respiration, according to the ordinary operation of physical laws: this, therefore, seems the most probable source of the expired water.

Lavoisier conceived that the water is generated in the lungs; hydrogen being evolved from the venous blood, and uniting with a part of the oxygen of the inspired air. But this liberation of hydrogen is not supported by a single proof, or shadow of proof; and we have every reason to believe that all the oxygen consumed in breathing is employed to form carbonic acid.

III. *Changes produced in the Blood by Respiration.*—Soon after the doctrine of the circulation had been generally received, the distinction between arterial and venous blood was pointed out, and it was understood that this fluid is changed from the latter into the former state in the lungs. Various conjectures were resorted to, to explain the nature and manner of this change. Some considered the alteration to be principally mechanical; conceiving that the blood, while in the pulmonary vessels, experiences a continual and violent agitation, by means of which, its particles, before loosely mixed, and confining of several heterogeneous substances, are communicated and perfectly united together, so that the whole mass acquires an uniform consistence. Baglivi supposed, that the blood was rarefied, and Helvetius, that it was condensed in the lungs; Boerhaave thought that its particles acquired that peculiar organization, which he deemed essential to the existence of perfect blood. Other philosophers, as Harvey, Boyle, Hales, and Haller, were of opinion, that the blood emitted some noxious or superfluous matter in its passage through the lungs. Some again supposed, that the change from venous to arterial was caused by something imparted from the air to the blood.

These vague speculations were soon superseded by the more certain information deduced from experiment and observation. We have already enumerated the proofs afforded by the researches of Lower, Cigna, Priestley, Lavoisier, Davy, and others, that the change of the blood from venous to arterial is effected by exposure to the oxygenous gas of the atmosphere in respiration; and that a similar change, in colour at least, is effected by such exposure out of the body: the alteration being accompanied, in both instances, with a change in the composition of the air.

The proofs, that respiration is the source of the change in colour just alluded to, that it is stopped in living animals when breathing is interrupted, and goes on again when the respiratory process is resumed, will be found in the article LUNGS.

But is there no other alteration in the properties of the blood consequent on respiration, besides its change of colour? Undoubtedly there must be such further alteration, for life is quickly ended, if this conversion of venous into arterial blood be stopped; and we shall presently state our opinion, that carbon is exhaled from the pulmonary vessels; but chemistry has not yet shewn us any difference of composition between the two kinds of blood.

“When (says Mr. Murray) we examine chemically the properties of arterial and venous blood, we find no other difference between them than that of colour. They contain the same principles, and are subject to the same changes from chemical agents. The difference of colour, however, points out some difference in composition, though it may be too slight to be discovered by analysis; and when we examine the phenomena of respiration, which are intimately connected with the change of venous to arterial blood, we find, that such a difference must exist.” *System of Chemistry*, vol. iv. p. 489.

Even the changes of colour of the blood are not well understood. We know that this fluid is converted from the scarlet to the black state, in the course of its passage through the capillary vessels of the body. But it undergoes the same change, when extravasated from a large artery, or when confined in an arterial tube between two ligatures. It never seems, however, to suffer the opposite change, except when in contact with oxygen gas, or with some substance capable of furnishing it.

That the passage of the air through the lungs in respiration is instrumental in converting the chyle and lymph, poured from the thoracic duct into the venous system, into blood; or, that it produces fibrine from the materials just mentioned, has been supposed and asserted; but without any direct proof. We cannot, indeed, see the chyle in the blood after it has gone through the lungs; but we know of nothing further than a mechanical admixture; and are completely ignorant of the circumstances accompanying and determining the generation of fibrine.

IV. *Theories of Respiration.*—The principal explanations of the phenomena detailed in the preceding divisions of this article, as exhibited in the air and blood, consequently to respiration, are detailed by Mr. Murray, in his *System of Chemistry*, vol. iv.; where they are followed by his own views of the subject.

Dr. Priestley, says he, considered these phenomena as owing to the disengagement of phlogiston from the blood in the lungs, and its combination with the air (*Philos. Transact.* 1776); a theory modified and rendered more comprehensive by Crawford (*Experiments and Observations on Animal Heat*). Regarding hydrogen as the phlogistic principle, and supposing it to exist in the blood in that state in which it is disengaged from vegetable substances by heat, the heavy inflammable air of the older chemists, the carburetted hydrogen of the modern nomenclature, he supposed that this hydro-carbon, as it was named, is communicated to the blood in the extreme vessels, by which the conversion from the arterial to the venous state is occasioned; in the lungs, he concluded, it is given out, and in its nascent state, or its transition to the elastic form, it combines, he supposed, with the oxygen of the air, and forms the carbonic acid gas and watery vapour expired, while the blood, deprived of its hydro-carbon, returns to the arterial state. The same explanation nearly was given by Lavoisier; at least he advanced the opinion, that the carbonic acid gas and watery vapour of the expired air are formed by the combination of carbon and hydrogen from the blood with oxygen in the lungs.

Lavoisier had also suggested, that the combination of oxygen with carbon might take place in the course of the circulation (*Mem. de l'Acad. des Sciences*, 1777, p. 191.), that the oxygen which disappears in respiration may be absorbed by the blood, while carbonic acid may be given out fully formed. This hypothesis was afterwards endeavoured to be established by Hallenfratz and Lagrange (*Annales de Chimie*, tom. ix. p. 261.) They observe, that venous blood exposed to oxygen acquires a vivid red colour, which soon changes to a purple hue; and that arterial blood placed in vacuo, or in contact with any gas which does not contain oxygen, quickly assumes the dark purple colour. They conclude, therefore, that the florid red colour of the blood is the result of the absorption of oxygen, while the dark venous colour arises from the intimate combination of that oxygen with a portion of the carbon and hydrogen which the blood contains. According to this theory, oxygen is absorbed by the blood in the lungs, remains in the arterial blood for a time in a state of solution, or loose combination,

ination, but it gradually passes, in the extreme vessels, into more intimate combination with carbon, forming carbonic acid, in consequence of which the blood passes to the venous state; and from this venous blood the carbonic acid is disengaged in the lungs, and a new portion of oxygen absorbed.

These two hypotheses have divided the opinions of physiologists. They are both, however, defective: their principles are not proved, and they involve suppositions incompatible with the laws which appear to regulate the chemical actions that proceed in the animal system. No proof is given, in the system of Crawford, of hydro-carbon being communicated to the blood in the extreme vessels; nor is it easy to imagine any source whence this principle in an insulated state can be derived; for, although it has been imagined by Crawford, that it may have its origin in the solid parts of the system being absorbed, this is refuted by the considerations, that this absorption is performed not by the veins, but by the lymphatics; that it is not sufficiently uniform, nor limited to carbon and hydrogen; that to whatever extent it may be carried, the blood must, in a state of health, deposit as much as is removed; and that there is no evident cause by which the carbon and hydrogen can be separated from the other elements, and be brought into binary combination. And, in the theory of Hallenfratz, though it were granted, that a portion of oxygen is absorbed by arterial blood, there is no proof that this is combined merely with carbon, and that carbonic acid, the result of this combination, is contained in venous blood. We have even proof that the latter supposition cannot be just; for, when arterial blood is exposed to carbonic acid gas until its colour is darkened, it does not recover its florid hue from subsequent exposure to oxygen (Priestley, *Experiments on Air*, vol. iii. p. 363. 365.), and is therefore not venous blood.

Neither are the changes which these hypotheses suppose, analogous to the usual chemical operations of the animal system, or sufficiently connected with the purposes which the blood serves in its circulation. They both suppose, that the changes which the blood undergoes, depend not on alterations in its composition, strictly speaking, but on the alternate communication and abstraction of a principle held by it in a state of solution, and which appears to serve no purpose in the animal economy, but is assumed merely to account for the phenomena of respiration. But when the general facility of combination in the principles of animal matter, and the tendency which the actions of the vessels have to form them into ternary or quaternary compounds, are considered, there is little probability in the supposition of the one hypothesis,—that oxygen should be absorbed by the blood in the lungs, without immediately altering its composition; that, without being attracted by any of the other principles of the blood, or influenced by the other chemical changes going on in the system, it should be merely combined with carbon, in the proportion necessary to form carbonic acid; and that this carbonic acid, without affecting the ultimate composition of the blood, should be carried the whole length of the venous circulation, and thrown out at the lungs; or in those of the other, that carbon and hydrogen should be brought into a state of binary combination in the extreme vessels, and should be held merely dissolved by the venous blood, until acted on by the oxygen of the air in respiration.

Still less are these changes connected with the known changes which the blood suffers; for no relation is traced between the processes of assimilation or of secretion, and the supposed communication of hydro-carbon, or the combination of carbon and oxygen, in the extreme vessels. In the

theory of respiration, the conversion of arterial into venous blood ought to be considered as connected with these processes; and this conversion, as well as that of venous into arterial blood, must be regarded as arising from changes in the ultimate composition of the known proximate principles of the blood, and not from the alternate communication and abstraction of a principle which it holds dissolved in it, or in what is termed a state of loose combination. According to this view of the subject, Mr. Murray gives the following explanation of these phenomena.

The blood is the source whence the animal products are formed. Its expenditure is supplied by the chyle, a fluid less completely animalized than the blood itself. The peculiar character of animal matter, with regard to composition, is a large proportion of nitrogen, and a diminished proportion of carbon. It may therefore be inferred, that in the extreme vessels, where the animal solids and fluids are formed, the general process will be the separation from the blood of those elements of which animal matter is composed; and that, of course, carbon, which enters more sparingly into its composition, will exist in the remaining blood in an increased proportion. This is accordingly the general nature of the conversion of arterial into venous blood. Nitrogen, hydrogen, and other elements, are spent in the formation of new products, and the proximate principles of the blood, probably the crassamentum chiefly, remain with an increased proportion of carbon. In this state it is exposed to the atmospheric air in the lungs, the oxygen of which abstracts its excess of carbon, and forms the carbonic acid expired, and this constitutes the conversion of venous into arterial blood.

There is little reason to suppose, that any combination of the oxygen of the air with the hydrogen of the blood takes place. The supposition that it does, and that this is the source of the watery vapours expired, originated in the hypothesis of Crawford, which supposed hydro-carbon to be disengaged from venous blood. No fact has been stated in its support; it is a combination which can apparently serve no purpose in the animal economy; for hydrogen exists in as large a proportion, (and even in a larger,) in animal as in vegetable matter. And the degree of evaporation from a moist surface, so extensive as that of the internal surface of the lungs, at the temperature of 96°, is adequate to account for the whole of the watery vapour expired.

The conversion of arterial into venous blood, is thus considered in connection with the other chemical changes going on in the system, and is subservient to them. In the extreme vessels, the constituent principles of the blood are expended in the nourishment of the solid fibre; in the formation of the secreted fluids; and in the support perhaps of the living powers. Of these principles, carbon is that contained in the smallest proportion in the solids and fluids; it is, therefore, that of which there is the least expenditure, and consequently it must be present in a larger proportion in the blood, after it has undergone these changes. To preserve the due proportion, and prevent it from accumulating, it must be discharged by some other process. Hence the necessity of the application of oxygen to the blood in the lungs, and the origin of the carbonic acid which is uniformly discharged. We thus, too, trace the process of animalization from the reception of the aliment to its completion. All animals live directly or indirectly on vegetable matter. The principal difference in the composition of vegetable from that of animal substances, is in the former containing a larger proportion of carbon. Respiration is the function by which this difference is established. The aliment received into the stomach, is soon formed into a fluid capable of assimilating

## RESPIRATION.

with the blood. It is conveyed to the lungs, and loses part of its carbon, or is partially animalized. It is then distributed through the system, and, in the extreme vessels, along with carbon, parts with so much hydrogen, oxygen, nitrogen, and other elements, as to leave carbon predominant.

It might be supposed, that in any view, such as that which has been now given, there must be some difficulty in conceiving that oxygen gas should combine with carbon with so much facility, at a temperature much lower than that which is in general necessary for their union, and this, too, with the intervention of the coats of the vessels through which the blood circulates. On attending, however, to the objection, it will be found to have no real force. Although carbon, in its solid and insulated form, requires to be raised to a high temperature to cause it to combine with oxygen, yet when it makes part of a ternary or quaternary combination, in which state its cohesion no longer opposes the combination, it is abstracted, and combined with oxygen at any natural temperature. It is thus that many vegetable and animal substances, when humid, are altered by exposure to the air, and carbonic acid formed. Blood itself is acted upon in this manner. It suffers a change precisely similar to that which it undergoes in the lungs, and this more or less rapidly, and to a greater or less extent, according to the quantity of oxygen present, and the degree of agitation used. Arterial blood was exposed by Fontana to atmospheric air for three minutes, when no perceptible alteration was occasioned in the purity of the air: they were then agitated together for three minutes: the volume of air was diminished and its purity impaired. When oxygen gas was substituted for atmospheric air, the alteration was still more considerable, its purity being diminished when agitation was avoided; and when it was agitated, the diminution in purity and volume was still greater. In all these experiments, carbonic acid was also produced. (*Opuscules Physiques*, pp. 334, 335.) They therefore prove, that oxygen can attract carbon from arterial blood. With venous blood, the formation of carbonic acid is, according to Luzzariaga, still greater. (*Dissertatio Inauguralis*, p. 53, 54.) If, therefore, oxygen can abstract carbon from the principles of the blood, under such circumstances, it is evident it must do so still more rapidly during respiration, where the circumstances are so much more favourable, where there is comparatively a high and uniform temperature kept up, where the blood is exposed on an extensive surface, and in a state of extreme division, and where that surface, as well as the air itself, are rapidly renewed.

Nor can it be supposed, that the thin membrane which forms the coats of the vessels through which the blood circulates can oppose an obstacle to this reciprocal action. Every humid substance is permeable through its whole substance to elastic fluids, and is penetrated by them. Animal membrane, in a much denser state than that which forms the coats of the extreme blood-vessels, is, when humid, pervious to gaseous fluids; and what is in point in the present case, through such membranes, when humid, oxygen can act on blood, and communicate to it the florid colour, the same as when blood is freely exposed to it. Thus, Priestley found by experiment, that if a quantity of black blood were inclosed in a moistened bladder, which was tied very close, on hanging it in a free exposure to the air, it acquired "a coating of a florid colour, as thick as it would have acquired if it had been exposed to the open air; so that this membrane had been no impediment to the action of the air on the blood." Mr. Hunter mentions a similar experiment: "I covered," says he, "the mouths of vessels filled with venous blood with gold-beaters' skin, touching the surface of

the blood, and the blood constantly became of a florid red on the surface, and even for some depth." (*Treatise on the Blood*, p. 62.) Nor is there any reason to believe, as has been contended, that in the living solids this property is suspended, for it is one connected merely with mechanical structure, and the influence of humidity. The blood, therefore, may be considered, when circulating in vessels so fine, as exposed to the action of oxygen nearly as if no membrane were interposed: a part of that oxygen approximated to it will combine with a portion of its carbon, and the carbonic acid, when formed, will, from its elasticity, recede and be discharged. The whole action is purely chemical, and precisely the same as that which is exerted between air and blood out of the body, favoured only by the circumstances of exposure, temperature, and agitation, under which it takes place." P. 502.—510.

After adverting to the arguments, by which it is shewn that no gas can pass through the membranes of the bronchial cells and pulmonary vessels from without, nor any substance pass from within through these parts, to unite in the lungs by ordinary chemical affinity, consequently that the carbonic acid is not formed by the union of carbon and oxygen in the blood; and to the facts, in which carbonic acid is formed in the lower animals and even in man, by the skin, where we have no proof of any absorption of oxygen, or passage of it through the animal textures, Mr. Ellis declares his opinion, in which we entirely coincide, that the carbon supplied in human respiration is truly an animal excretion, performed by the exhalent vessels, which exist in such wonderful numbers in the lungs; consequently, that it depends primarily, like other excretions, on the due circulation and distribution of the blood, and is more or less affected by all its variations. The changes in its quantity have been found very considerable, according as the individual was at rest or in motion, fasting or with a full stomach, &c. in the experiments already noticed of Lavoisier and Seguin. We conceive, then, that the carbon, thus exhaled or excreted in the lungs, combines in the air-cells with the oxygen of the atmosphere to form the carbonic acid expired.

As the emission of carbonic acid in respiration is carried on through the whole period of living action, and is essential to the continuance of it, some ulterior source must be provided, from whence its supply may be duly maintained.

"To the organs of digestion, assimilation, and secretion alone, we are enabled to trace it; but the mode in which it is reduced to that state in which it is afterwards expelled by the surfaces of the lungs and skin, involves a knowledge of the nature and qualities of our food, of the various and successive changes which it is made to undergo in the system, and of its distribution by the blood to the different organs of secretion, according to the several uses which it is afterwards destined to answer: concerning all of which subjects, we have of late succeeded in getting rid of much error and absurdity, but have not in any instance attained to complete knowledge." Ellis's Inquiry, ch. 5.

V. *On the Respiration of the different Gases.*—No æciform fluid, says Dr. Boerhaave, except the compound of oxygen and azote which exists in the atmosphere, is adapted to the permanent support of life. Of the other gases, there are some which, on account of their irritating nature, it is absolutely impossible to receive into the trachea; these properly constitute the nonrespirable gases. There are, however, others which it is possible to inspire, though their employment is followed sooner or later by the extinction of life. We shall detail some of the principal experiments that have been performed on this subject, as the nature of the change produced

duced upon the blood by common respiration may be in some measure illustrated, by observing the effects which follow the use of the other gaseous bodies.

Soon after the discovery of the power which the oxygenous part of the atmosphere possesses, of supporting animal life, several trials were made of the effects which would result from breathing it in an unmixed state. The accounts given by those who were the subjects of these trials were various; Dr. Priestley, who first made the experiment, conceived that he felt an agreeable lightness in the chest (*Obs. on Air*, v. ii. p. 162.); some persons supposed that it produced exhilarating effects upon the system, while others imagined that the employment of this gas was followed by uneasiness and pain about the region of the thorax. These different sensations must be attributed, in a great degree, to the effects of imagination; in part, however, they may be ascribed to the gas which was employed in the earlier period of the pneumatic experiments having been often in an impure state, mixed with acid, acrid, or metallic particles. A difference in the effects produced by the respiration of the gas, ought perhaps, in some degree also, to be imputed to the manner in which it was received into the lungs, whether only in small quantities, or by deep and laborious inspirations, and whether it was employed in a condensed or a rarefied state.

As Dr. Priestley was the first person who, himself, respired oxygenous gas, so he was likewise the first who observed the effects which it produced upon animals altogether immersed in it. His experiments were performed upon mice; they decidedly proved the power which this gas possesses of supporting animal life, but no other certain conclusions can be deduced from them. M. Lavoisier afterwards turned his attention to this subject, and in the experiments upon guinea pigs, to which we have already referred, he noticed with more accuracy the effects resulting from the respiration of oxygen. He examined the state of the internal organs of animals which had been for some time confined in this gas, and he conceived that a degree of redness and turgescence of the vessels was produced, and other effects which indicated that the sanguiferous system had been in a state of increased action. (*Soc. Roy. de Médecine*, 1782, 1783, p. 576.) There is, however, reason to infer, that in this case, either the gas employed was in an impure state, or that there were some circumstances attending the situation of the animals, or the manner in which the experiment was conducted, which affected the results, for the same philosopher, in the subsequent memoir of 1789, where there appears to have been the greatest attention to accuracy, and where the most perfect apparatus was employed, forms entirely opposite conclusions. In this paper, we are informed, that he confined guinea pigs in pure oxygen, and in mixtures of oxygen and azote, in different proportions, until the former constituted only one-fifteenth part of the compound. In all these cases, he found that the same quantity of oxygen was consumed, a circumstance, he observes, in which respiration differs remarkably from combustion, though, in many respects, these operations are similar to each other. The effects produced upon the animals were precisely the same, whether they were confined in pure oxygen, or in any of the mixtures of it, except that when the proportion of azote was very large, they exhibited marks of drowsiness. The author expressly informs us, that neither the temperature nor the circulation were in any respects affected by the inspiration of pure oxygen for the space of several days. (*Acad. des Sciences*, 1789, p. 573.) These experiments must be considered as very

valuable; there is no reason to doubt their accuracy, and they may be relied on with more confidence, as the author seems to have had no peculiar theory in view when he performed them; indeed the results are different from what we might previously have expected, and are unfavourable to the analogy which Lavoisier had always endeavoured to establish between respiration and combustion.

We have an account by Dr. Higgins of the respiration of pure oxygen by the human subject; in one experiment, thirty-eight pints of this gas were respired without interruption. No inconvenience was experienced, a sense of warmth was, however, produced in the chest, and the pulse was considerably quickened, (*Minutes of a Society*, &c. p. 144-6.) Dr. Higgins, in a second experiment, breathed a quantity of oxygen under an additional pressure, and by very full inspirations. He conceived that by these means its consumption was much promoted (*ibid.* 152.); but more numerous and accurate experiments will be required before this inference can be fairly established. *Essay on Respiration*, p. 139-144.

In the year 1794, Dr. Beddoes published his experiments upon this subject. (*On Facitious Air*, pt. i. p. 13.) They were performed upon rabbits, and the attention was principally directed to an examination of the state of the internal organs of the animal, after it had been subjected for some time to the influence of pure oxygen. In detailing the results, we see such obvious marks of the influence of the author's pre-conceived notions, that our confidence in them is much diminished; and this unfavourable impression is strengthened by finding that they do not coincide with the reports of other very accurate observers. See *Bollock on Respiration*, p. 144, et seq.

Mr. Davy has also recorded some trials, which he made with oxygen gas; the results of which, so far as they regard the chemical changes of the air itself, we have noticed in a previous part of this article. *Researches*, p. 444.

Messrs. Allen and Pepys made some experiments on the respiration of oxygen. The pulse was raised about 15 beats in a minute, a gentle glow and perspiration were produced over the whole body, and nothing else remarkable occurred. The respiration of the gas was continued about ten minutes in these trials; and the effects soon subsided. We have detailed the results of their observations concerning the changes of the air, in that division of this article in which the quantity of carbonic acid, produced by breathing, is mentioned.

It thus appears that we have no direct proof that the respiration of oxygen, for a short period, is injurious to the animal economy. Whether a much longer use of the gas would be hurtful, and what peculiar morbid action or condition of parts would be induced, we have no means of determining.

Among the remaining respirable gases, that which appears to be the least injurious to the living body is the oxyd of azote. This acrimiform fluid was first discovered by Dr. Priestley, and was by him supposed to be "in the highest degree noxious to animals." (*Obs. on Air*, v. ii. p. 55.) The society of Dutch chemists, who afterwards examined its properties with more accuracy, coincided with Dr. Priestley, as to its effects upon animal life. (*Journal de Physique*, t. xliii. p. 329.) The experiment was, however, repeated by Mr. Davy, and he discovered not only that this gas may be respired for a short time without inconvenience, (four or five minutes,) but that the employment of it is succeeded by a singular excitement of the nervous system, which differs from that produced by alcohol and

## RESPIRATION.

opium, in not producing a subsequent state of exhaustion. The description of its effects in the "Researches" is very interesting. Mr. Davy infers from his experiments, that this gas is absorbed in large quantities by the venous blood. This blood, when exposed to the gas out of the body, becomes of a brighter purple, and carbonic acid is formed. We have no doubt, therefore, that carbonic acid is formed when this gas is respired; the gas being decomposed, so that the carbon of the venous blood can unite with its oxygen. We have already spoken at length against the notion of any air being absorbed by the blood in breathing; and we may refer to Mr. Ellis's Inquiry, chap. iv., for satisfactory arguments against the supposed absorption of this gas in particular.

Hydrogenous gas has been frequently respired, and it is now pretty generally agreed, that it is altogether passive when received into the lungs, and that death succeeds the employment of it in consequence of the exclusion of oxygen, in the same manner as by suffocation, or drowning. M. Lavoisier distinctly ascertained this fact, in his experiments related in the memoir of 1789, and it has been since confirmed by Mr. Davy. (Researches, p. 466.) It must be remarked, however, that a contrary opinion respecting the effects produced by the respiration of hydrogen has been maintained by some eminent chemists, even by Dr. Priestley himself (Obs. on Air, v. i. p. 229.); but his experiments were made in the earlier period of the pneumatic chemistry, when the gases were frequently employed in an impure state, and the experiments of Mr. Davy clearly demonstrate that hydrogenous gas produces different effects upon the system, according to the substances from which it is procured.

The experiments that have been made upon the subject of azotic gas are few and imperfect; it has been generally supposed, that it exercises no noxious effects upon the blood, but, like hydrogen, destroys life simply by preventing the access of oxygen. Dr. Higgins indeed remarks, that an animal dies sooner when immersed in this gas, than from the simple interruption to respiration (Minutes of a Society, p. 133.); but we are not informed upon what data this opinion is founded. Mr. Davy likewise experienced the sense of suffocation more speedily from the use of azote, than from that of hydrogen, but it appears that the gas employed in the experiment contained a quantity of carbonic acid, to which we may, with great probability, ascribe its noxious effects; and the same philosopher, when speaking in general terms of the action of azote in respiration, seems to consider it as merely excluding oxygen. This opinion is adopted by Dr. Thomson, and was uniformly maintained by M. Lavoisier. It would certainly appear reasonable to conclude à priori, that a substance which enters so largely into the composition of the atmosphere, and which consequently composes so great a proportion of the contents of the lungs, could not exercise any noxious effects upon the animal system.

The only remaining gases which can be received into the lungs are the carbonated hydrogen or hydro-carbon, sulphurated hydrogen, and carbonic oxyd. They occasion death immediately, but produce some change in the blood. If hydro-carbon be inspired in an undiluted state, it is followed by instant death; and when employed in small quantity only, mixed with atmospheric air or with oxygen, if it be used for any length of time, it induces vertigo, dimness of sight, convulsions, loss of sensation, and, in short, every symptom of approaching dissolution. It evidently acts more rapidly and powerfully than those gases which merely exclude oxygen from the blood, and must consequently be considered as exercising a positively noxious influence upon the animal economy. For an account of the respiration of

fulphuretted hydrogen, see the Journal de Physique, vol. lvi. p. 35.

All the remaining gases are found to be strictly non-respirable, *i. e.* incapable of being admitted into the trachea. It is obvious that this must be the case with the irritating acid or alkaline gases, and with the nitrous gas, which, during its passage into the lungs, must unavoidably be brought into contact with oxygen, and thus produce nitrous acid vapour. The only substance, respecting the respirability of which there could be any doubt, is the carbonic acid gas, which, though possessed of the decided characteristics of an acid, exhibits them in a much slighter degree than that in which they generally exist. The impossibility of taking it into the lungs, even by the most powerful voluntary efforts, when it composes a large proportion of the air, was, however, proved by the experiments of M. Pilatre de Rozier, executed with that intrepidity which formed so remarkable a trait in the character of this philosopher. Bostock's Essay, p. 149—153.

He went into a brewer's tub, while full of carbonic acid gas, evolved by fermentation. A gentle heat manifested itself in all parts of his body, and occasioned a sensible perspiration. A slight itching sensation constrained him frequently to shut his eyes. When he attempted to breathe, a violent feeling of suffocation prevented him. He fought for the steps to get out; but not finding them readily, the necessity of breathing increased, he became giddy, and felt a tingling sensation in his ears. As soon as his mouth reached the air, he breathed freely, but for some time he could not distinguish objects: his face was purple, his limbs weak, and he understood with difficulty what was said to him. But these symptoms soon left him. He repeated the experiment often, and always found, that as long as he continued without breathing, he could speak and move about without inconvenience; but whenever he attempted to breathe, the feeling of suffocation came on. Journal de Physique, vol. xxviii.

Blumenbach made an experiment on three dogs of nearly the same size, to shew in a comparative view how long three different aerial fluids could support life. He prepared a bladder with a pipe attached to it, and holding about 20 cubic inches. This, filled with oxygen, was tied in the trachea, and the animal died in 14 minutes. The second animal perished in six minutes, when the same bladder, filled with atmospheric air, was placed in the same way in the trachea. The bladder containing the air, at the end of the last experiment, was put into the trachea of the third animal, which died in four minutes. Instit. Physiolog. 1798, p. 114, note *g*; or more at length in his Medicinische Bibliothek, vol. i. p. 174, et seq.

VI. *Effects produced on the Air by the Respiration of Animals.*—The results of observation warrant us in asserting that no living being can subsist long without a supply of fresh air. That insects die, when their stigmata are covered with oil or honey, has been long known. "Oleo illito insecta omnia exanimantur," says Pliny. Mr. Derham found that wasps, bees, hornets, and grasshoppers, seemed dead in two minutes, when placed under the exhausted receiver; but revived in two or three hours, on being restored to the air, even although they had remained in vacuo 24 hours. (Physico-Theology, p. 8, 7th edit.) Snails survived several hours in the exhausted receiver, newts two or three days, and leeches five or six. (Hutton's Math. Dict. art. *Air-pump*.) Zoophytes, according to Davy, require air in the water which they inhabit, and act on it like fishes. (Beddoes's Contributions, p. 138.) When some pepper-water had remained in vacuo 24 hours, some of its animalcules

were dead, and some alive. (Physico-Theol. p. 8.) Spallanzani never found any animalcules produced in vegetable infusions in vacuo. When infusions, containing animalcules, were placed under the exhausted receiver, they lived many days, but perished sooner than others of the same kind in the open air. (Tracts, p. 1, 2.) Hooke found that the cels of vinegar died in a very short time, when the fluid was put into a phial, and stopped close. (Microgr. p. 217.) Scheele inclosed leeches in a phial, with a little air: they lived only two days, although they would have lived as many years, if the water had communicated with the air. Mr. Ray remarked, that fishes cannot live in water without air: they will live in a vessel of water with a narrow mouth for months or years; but if the vessel be stopped, so as wholly to exclude the air, or interrupt its communication with the water, they will be suddenly suffocated. (Wisdom of God in the Creation, p. 81.) Dr. Priestley confined several small fishes in a vessel, containing three pints of rain water, that had been previously well boiled to deprive it of its air, and they lived only between three and four hours. (Obl. on Air, vol. v. p. 139.) Mr. Davy introduced a large thornback into a jar, containing three cubic inches of water, which had been deprived of its air by distillation through mercury: he was very quiet for four minutes and a half, but then began to move about, and, in seven minutes, had fallen on his back, but still continued to move his gills. In eleven minutes, he was motionless, and when taken out, after thirteen minutes, he did not recover. (Researches, p. 367.) Amphibious animals, likewise, cannot live without air, but its deprivation is not immediately fatal to them. Frogs and toads bear the pump for two or three hours, and a frog recovered on exposure to the air, after remaining in vacuo seemingly dead for eleven hours. Hence we see, that to all these animals, whether inhabiting the air or the water, a constant renewal of fresh air is required, while the actions of life continue. What then are the changes produced on atmospheric air, by these several classes of animal beings, whereby it is rendered so essential to the maintenance of vital action?

For the first and most accurate knowledge we possess concerning the changes which the air suffers by the respiration of insects, we are indebted to the labours of Scheele, who placed bees and flies in phials with air, and found the oxygen removed, and carbonic acid gas substituted in its place. (On Air and Fire, p. 148—155.) M. Vauquelin examined the subject more accurately. The experiments of this excellent chemist were made on the grasshopper (*Gryllus viridissimus*), which is described as having 24 stigmata, or breathing pores, ranged parallel with, but exterior to, two white lines, extending longitudinally on the middle of the belly. In this insect they are of an oval form, but they vary in shape in different insects; and it is chiefly by their mediation, that the changes on the air are effected. A female grasshopper was placed in eight cubic inches of atmospheric air: it breathed from 50 to 55 times in a minute, and lived 36 hours. The air had not sensibly diminished in volume, but, when examined by the test of lime-water, carbonic acid was detected; and after this was removed, the remaining air still extinguished a taper. When many grasshoppers were put at the same time into a given bulk of air, and left till they died, the oxygen gas was nearly, but not entirely, consumed; and phosphorus melted in the residual air, when heat was applied, but burned very little. A male grasshopper lived 18 hours in six cubic inches of oxygen gas: its respiration was oppressive, and it breathed from 60 to 65 times in a minute. The volume of air was not sensibly diminished, but it lost  $\frac{1}{10}$  of its bulk by being

washed in an alkaline solution. (Ann. de Chimie, tom. xii.) From these facts we learn, that insects, by their respiration, consume the oxygenous portion of the air; that carbonic acid is, at the same time, produced; and that, when all the oxygen gas has disappeared, the animal no longer survives.

M. Huber found, that bees very speedily die, when put into nitrogen gas; but that they survive in a close vessel of atmospheric air, until almost the last atom of its oxygen gas is consumed. (Mem. sur la Germination, &c.) We likewise confined, says Mr. Ellis, a number of flies in a flask, containing nine cubic inches of air, and then inverted it into a tall glass of mercury. By the third day, the flies were all dead, and the mercury had risen considerably into the neck of the flask. The residual air lost about  $\frac{1}{10}$  of its bulk by agitation with lime-water, and the remainder did not suffer the smallest diminution by being placed in contact for two days with phosphorus. These results, therefore, agree with those obtained by Vauquelin, and prove farther, that, by the respiration of flies, the whole of the oxygen gas of the air disappears, and that a bulk of carbonic acid nearly equal thereto is formed. The small diminution of bulk, also, which the air suffered, is to be regarded as a necessary consequence attending the conversion of oxygen gas into carbonic acid, and which, as it accounts for the whole loss the air experienced, seems to authorize the conclusion, that while the oxygen gas had, in this case, completely disappeared, the nitrogenous portion of the air continued undiminished, and probably unaltered.

The researches of Spallanzani and Reaumur further shewed, that the ova of insects cannot be evolved without air; that the larvæ cannot exist without it, nor undergo their change to the pupa state; and that it is equally essential to the transformation of the latter into the perfect insect. *Rapports de l'Air avec les êtres Organisés*, tom. i. *Memoires pour servir à l'Hist. des Insectes*, tom. ii.

M. Vauquelin proceeded next to investigate the changes produced on the air by the respiration of the vermes class of animals. He confined a red slug in twelve cubic inches of atmospheric air, and it lived 48 hours. The air was not sensibly diminished in volume, but it extinguished candles, and copiously precipitated lime from water. Phosphorus was melted in this air, but did not suffer any combustion or change of colour. A snail (*helix pomatia*) was next put into twelve cubic inches of atmospheric air, and lived four days. The oxygen gas entirely disappeared; for the residual nitrogen gas contained not an atom of vital air, and, consequently, phosphorus did not burn in it at all: it contained, however, carbonic acid. Slugs and snails, therefore, require fresh air while in an active state, the oxygen gas of which, by the function of their respiratory organs, is made completely to disappear, and a quantity of carbonic acid is produced, while the nitrogenous portion of the air remains unaltered: and when these changes are effected, living action speedily comes to an end. So exactly do these animals separate the oxygenous from the nitrogenous portion of the atmosphere, that M. Vauquelin suggests the employment of them for eudiometrical purposes. *Ann. de Chimie*, loc. cit.

The numerous experiments of Spallanzani on worms, snails, slugs, &c. confirm the statements of Vauquelin in all essential points. (*Memoirs on Respiration*. *Rapports de l'Air*.) He also made experiments on muscles, and several marine testacea: they consumed the air of water in which they were confined, and the water then attracted more, so as to consume all the oxygen when a small quantity of air was confined in contact with it.

## RESPIRATION.

We are indebted to Messrs. Humboldt and Provençal for some experiments on the respiration of fishes, which possess great accuracy. Their attention was first directed to ascertain the quantity and composition of the air that exists naturally in river-water. For this purpose, they filled glass balloons with given quantities of water, taken from the river Seine, and expelled the air from it by submitting it to ebullition. The air that came over was received in vessels filled with mercury, or with distilled water recently boiled, that no foreign air might mix with that obtained from the water in the balloon. From the results of ten experiments, conducted in this manner, they found, that the water of the Seine contained rather less than  $\frac{1}{3}$ th of its volume of air. This air they farther found to be composed of about  $\frac{1}{10}$ th oxygen, with from 6 to 11 per cent. carbonic acid, and the remainder was nitrogen gas. Mem. d'Arcueil, tom. ii.

Having thus determined the quantity and kind of air contained in a given volume of river-water, these chemists proceeded to ascertain the changes which it experienced by the respiration of fishes. With this view, they confined young fishes in bell-glasses of river-water, inverted over mercury; and suffered them to remain till their respiration became laborious. The animals were then withdrawn, and the water, in which they had respired, was transferred into the balloon, and its air expelled, by submitting it to ebullition, in the manner before stated. Seven tenches were, in this manner, confined in 4000 cubic centimeters, equal to 250.5 cubic inches of river-water, where they remained eight hours and a half. A portion of this water, equal to 2582 cubic centimeters, or 161.5 cubic inches, was then transferred from the glass-bell into the balloon, and its air expelled by heat. The air, thus obtained, measured 453 parts, at temperature 50° Fahrenheit. These 453 parts were then washed in lime-water, by which they were reduced to 300, so that 153 parts of carbonic acid were thus removed. The residue was afterwards analyzed by combustion with hydrogen, and by mixture with nitrous gas; and the means of three analyses afforded 0.035 of oxygen; wherefore it is concluded, that the 453 parts of air, obtained from water which had been in contact with the respiratory organs of fishes, consisted of 10.5 oxygen, 289.5 nitrogen, and 153.0 carbonic acid gas. But by former experiments, it was found, that an equal volume of pure river-water afforded 524 parts of air, consisting of 155.9 oxygen, 347.1 nitrogen, and 21.0 carbonic acid; consequently, say these chemists, these seven tenches have *absorbed*, in eight hours, 145.4 of oxygen, and 57.6 of nitrogen gas; and they have produced in the same time 132 parts of carbonic acid. (Mem. d'Arcueil, t. ii. p. 376.) Mr. Ellis has pointed out some sources of fallacy, from which these apparent results may have arisen, and it is probable from analysis, that in fishes, as in other animals, the change produced by respiration is the conversion of oxygen into an equivalent portion of carbonic acid.

The changes which the air undergoes from the respiration of REPTILES are detailed in that article. Its alterations in the breathing of mammalia and birds are the same as in man.

“The preceding facts,” says Mr. Ellis, “sufficiently shew, that various animals, in all the foregoing classes, and in every stage and form of their existence, require the presence of oxygen gas to maintain the functions of life; that this gas, by the exercise of these functions, is converted into carbonic acid: and that the degree in which this conversion proceeds, depends much on the healthy condition of the animal, and the vigour of its circulating system. Since, also, in every instance where the experiments have been

made with the requisite accuracy, the bulk of carbonic acid produced, nearly or exactly equalled that of the oxygen which disappeared, we may conclude, from analogy, that such is universally the extent to which this change in the air takes place in animal respiration; and since, farther, the nitrogen gas of the air appears to suffer no necessary change in the exercise of this function, we may also conclude, that, as far as regards the air, the substitution of an equal bulk of carbonic acid for the oxygen gas that is lost, comprises the only essential change which the atmosphere experiences during the performance of this animal process. We have before maintained that the oxygen of the air does not enter the animal system, either by the living function of absorption, or by the operation of chemical affinity; and have consequently concluded, that the union of this substance with the animal carbon takes place exterior to the vessels of the living animal.” Further Inquiry, p. 271.

*Animal Heat.*—Taking the specific caloric of water at 1.0000, Dr. Crawford found that of arterial blood to be 1.0300, and that of venous blood 0.8928; that of oxygen gas compared to water, as 4.7490 to 1.0000; of nitrogen, 0.7936; atmospheric air, 1.7900; and of carbonic acid gas, 1.6454. The power of oxygen gas to supply heat, says Mr. Berthollet, is well known, and there is no substance which suffers so much of it to escape in the changes of its constitution.

In the respiration of animals, as well as in the germination of seeds, and the vegetation of plants, the oxygen gas of the atmosphere is converted into carbonic acid. Since the specific caloric of the latter is little more than one-third of that which the oxygen gas itself previously contained, it necessarily follows, that a large quantity of caloric is liberated, whenever this conversion of gases takes place. Now, in the living processes just alluded to, the presence of caloric is very obvious; we refer for proofs on these subjects, to the articles HEAT, *Animal*, MAMMALIA, BIRDS, FISHES, INSECTS, REPTILES, and VERMES, in which the facts connected with their vital temperature are detailed; also to the two “Inquiries” of Mr. Ellis.

Since, then, all animals possess a temperature exceeding that of the medium which they inhabit, and since this, in man and the superior animals, varies but little under every vicissitude of heat and cold, consistent with the due performance of the animal functions, there must exist in all cases appropriate means of sustaining this function. But no living powers of the animal system are sufficient for this purpose, independent of the concurring aid of external agents. No supposed attrition between the contiguous soft parts of the animal; no friction between the vessels and globules of the blood; no action of the solid parts upon one another; no circumstances arising out of digestion or fermentation in the living body; no imagined combustion of phosphorus in the blood; no liberation of the phlogistic or any other principle, through the system, can be received as sufficient to account for the uniform height and steadiness of this temperature. As, therefore, the animal system, by virtue of its own powers, is unable, within itself, to produce this high degree of heat, to what external agent shall we have recourse, and to what organs shall we refer the production of that more or less elevated temperature which is observable in all animals.

Insects, worms, and fishes, which have no respiratory structure similar to that of the lungs; and reptiles, the surface of whose lungs, in proportion to that of the body, is comparatively small, and whose blood, at each circulation, is but partially exposed to the influence of the air, possess a

degree of heat but little above that of the medium in which they live; while the mammalia have a temperature considerably higher; and birds, whose lungs bear the largest proportion to their bodies, are the warmest of all animals. The observation of these facts led naturally to the opinion, that the temperature of animals was immediately connected with the functions of the respiratory organs; and an abundance of facts, collected and arranged by Mr. Ellis, prove that the small excess of temperature, which not only the inferior animals, but which vegetables also possess, is actually derived from the decomposition of the air by these several classes of beings, so long as living action continues. "No explanation, however," says Mr. Ellis, "of the mode in which the air contributes to sustain animal heat, was attempted, till after the great discovery of latent heat by Dr. Black. That excellent philosopher having already proved that the change effected in the air by respiration, consisted in the formation of carbonic acid, similar to what happens in many examples of combustion, ascribed the production of animal heat to the decomposition of the air in the lungs, by which its latent heat was rendered sensible, in the same manner as it is given out in combustion. The blood, in its passage through the lungs, had, he conceived, its temperature by this means raised; and thus was rendered capable of communicating heat to all parts of the body, in the course of its circulation through the system. To this it was objected by Dr. Cullen, that, if true, the temperature of the body ought to be greatest in the lungs, and to diminish gradually, as the distance from the lungs increases, which is not according to fact. This difficulty was removed by the ingenuity of Dr. Crawford, who, by a happy extension of Dr. Black's doctrine, maintained, that the heat, liberated by the decomposition of the air in the lungs, passed into the blood, and exhaled in that fluid in the form of latent, or, what is now termed, specific heat, in consequence of which its temperature was not raised; and that this heat, by other chemical changes, was given out by the blood in a sensible form during its circulation.

"In what manner, then, does the air, breathed by the superior animals, give out its heat, to support that high degree of temperature above the surrounding medium, which they all possess? We have seen reason to conclude, that the inspired air is decomposed in the bronchial cells of the lungs, and that all its oxygenous portion which disappears, is converted into carbonic acid, by carbon emitted from the exhalant surface of those organs. During this gradual conversion of the oxygen gas, a quantity of specific caloric, much greater than what is necessary to maintain the elasticity of the carbonic acid that is formed, is necessarily set free; and to this excess of heat, thus constantly liberated in the lungs, by the decomposition of the air, do we look as the source of that superiority of temperature, above the surrounding medium, which man and other animals, under every vicissitude of climate, are enabled to exhibit and maintain.

"But if a quantity of caloric be thus constantly disengaged in the lungs, it may be expected that the blood, in its transmission through those organs, should acquire a certain portion of it. To ascertain this point, Dr. Crawford, pursuing the discoveries of Drs. Black and Irvine, mixed together certain quantities of water, at the temperature of  $53^{\circ}$ , with separate portions of arterial and venal blood; and then measuring the heat of the mixture, at different successive periods, till coagulation took place, he found that the water containing arterial blood preserved a superiority of temperature over that mixed with venal blood; and, from

the results of several trials, he concluded, that the specific heat of the arterial blood of a dog, was to that of the venal, as 114 to 100, and that of a sheep as 115 to 100, or as  $11\frac{1}{2}$  to 10. (On Animal Heat, p. 279.) These results derive confirmation from the experiments of Mr. Coleman, who, in order to discover the relative specific heat of arterial and venal blood, while yet retained in the system, strangled a cat, and immediately opened its chest, while the blood in the left ventricle was still florid. He then introduced a thermometer, through an opening in the pericardium on each side of the heart, and it stood at  $98^{\circ}$ : in the left ventricle the temperature was only  $97^{\circ}$ , and in the right ventricle it was nearly  $99^{\circ}$ . In fifteen minutes, however, instead of the right ventricle possessing two degrees of heat more than the left, it was found to have four degrees less. Mr. Astley Cooper repeated this experiment in different ways, and found invariably, that although the venal blood was superior in temperature at first, yet before coagulation was complete, the arterial became from three to six degrees warmer. (On Suspended Respiration, p. 42, et seq.) These facts afford clear and decisive proof, that the specific heat of the arterial blood exceeds that of the venal, and demonstrate, likewise, that this excess is obtained during the passage of that fluid through the lungs.

"Admitting the lungs, then, to be the organs in which, by a decomposition of the air, the blood, as it passes through them, obtains its heat, it is next required to shew the sufficiency of this decomposition, to supply heat enough for the maintenance of that superiority of temperature, which the warmer blooded animals possess." (Inquiry, p. 234-236.) For an account of the mode in which this was explained by Dr. Crawford, see HEAT, Animal.

Although this explanation of the production of animal heat appears simple and satisfactory, and has been held adequate to account for the phenomena by such philosophers as Black, Crawford, Lavoisier, and La Place, the evidence on which it rests is not so clear as to have commanded universal assent, or entirely set aside objections. It has, indeed, been generally allowed, that respiration, and the changes it produces in the air and animal fluids, are essential conditions of the evolution of the caloric in animals; but it has been thought, that there are other circumstances, hitherto perhaps not well understood, which influence the phenomena.

In external appearance the blood is the same in all the vessels of the fœtus; is this any proof that its temperature is owing to the conversion of oxygen gas into carbonic acid?

Is the uniformity of temperature in the higher animals, under varying states of respiration and circulation, and the consumption of various quantities of oxygen, whether in the same or different individuals, consistent with the theory? and can local variations of temperature be explained from it?

Some recent investigations of Mr. Brodie are particularly calculated to increase our doubts on the subject. Having pithed or decapitated animals, he kept up artificial respiration, and thus maintained their circulation. The blood continued to be changed in the lungs from venous to arterial, and from arterial to venous, in the general circulation.

The respective colours of the two kinds of blood could not be distinguished from those which they exhibit in living and healthy animals. Yet the temperature of an animal thus heated, sunk faster than that of another simply killed and left to itself. The following table exhibits the results of such a comparative experiment.

Time.	Rabbit with artificial Respiration.		Dead Rabbit.	
	Thermometer in the Rectum.	Thermometer in the Pericardium.	Thermometer in the Rectum.	Thermometer in the Pericardium.
Before the experiment	100½		100½	
30 minutes -	97		99	
45 - -	95½		98	
60 - -	94		96½	
75 - -	92		95	
90 - -	91		94	
100 - -	90½	87½	93	90½

The animal, in whom artificial breathing was kept up, instead of having its heat maintained by the conversion of arterial into venous blood, and *vice versa*, was thus actually cooled by the air conveyed into its chest.

Having thus ascertained, that the ordinary changes are effected in the blood by its circulation and artificial respiration in a decapitated animal, Mr. Brodie proceeded to shew, that the oxygen of the air undergoes its usual conversion into carbonic acid. He found, that a living rabbit formed 50—56 cubic inches of carbonic acid in an hour; a decapitated animal, in whom artificial respiration was kept up, emitted 40—48 cubic inches in the same time. The thermometer in the rectum of the latter had fallen from 97 to 90, while in another rabbit left to itself, but similarly treated in all other respects, it had fallen only to 91. In a rabbit poisoned with woorara, or the essential oil of bitter almonds, not decapitated, and in which artificial breathing was kept up, 51 cubic inches of carbonic acid were emitted in an hour. The thermometer in the rectum had sunk to 91 in 30 minutes; while it stood in another animal treated exactly the same, excepting the artificial breathing, at 92.

These experiments seem fully to warrant Mr. Brodie's conclusion, "that in an animal in which the brain has ceased to exercise its functions, although respiration continues to be performed, and the circulation of the blood is kept up to the natural standard, although the usual changes in the sensible qualities of the blood take place in the two capillary systems, and the same quantity of carbonic acid is formed as under ordinary circumstances; no heat is generated, and (in consequence of the cold air thrown into the lungs) the animal cools more rapidly, than one which is actually dead."

See the Croonian Lecture on some physiological researches, respecting the influence of the brain on the action of the heart, and on the generation of animal heat; Phil. Transf. 1811, p. 36.

And further experiments and observations on the influence of the brain in the generation of animal heat, Phil. Transf. 1812, p. 378.

On the subject of this article, the most valuable works, both for the collection of facts from various sources, for original views and researches, acuteness of investigation, and close reasoning, are those of Mr. Ellis; entitled, "An Inquiry into the Changes induced on atmospheric Air by the Germination of Seeds, the Vegetation of Plants, and the Respiration of Animals," 1807. And, "Further Inquiries, &c." 1811. Dr. Boitock's "Essay on Respiration," 1804, is a very valuable collection of the facts known on this subject up to that time. The preceding article is derived in greatest part from these works. We may refer also to Thomson's System of Chemistry, book 5. ch. 3. § 2; and Murray's System of Chemistry, book 9.

ch. 2. § 1. To the valuable memoirs of Messrs. Allen and Pepys, "On the Changes produced in atmospheric Air and Oxygen Gas by Respiration," Phil. Transf. 1808; and "On Respiration," *ibid.* 1809. To those of Lavoisier in the Memoires de l'Academie des Sciences, 1777 and 1780; and in the Société Royale de Médecine, 1782—3. Of Lavoisier and Seguin in the Mem. de l'Acad. 1789, 1790. See also Crawford, on Animal Heat; Goodwyn, on the Connection of Life with Respiration; Menzies, on Respiration; Coleman, on Suspended Respiration; Davy's Researches; Spallanzani's Memoirs on Respiration, and his Rapports de l'Air avec les êtres Organisés, t. 3. 8vo. Geneva. Priestley on Air. Seguin in Annales de Chimie, t. 5. and 21.

RESPITE, RESPECTUS, in *Law*, &c. a delay, forbearance, or prolongation of time, granted any one for the payment of a debt or the like.

Menage derives the word *respite* from the Latin *respectus*; as *despite* from *despectus*. Du-Cange will rather have it come from *respirare*, to breathe; respite being, in effect, a breathing-while, granted a debtor, &c.

In the customary of Normandy, respite is a judicial delay or demur, given to procedures.

RESPITE, *Letters of*, or CREDIT. See LETTERS.

RESPITE of *Homage*, is a forbearance of the homage due from the vassal, or tenant, holding by homage, or by knight-service, to his lord.

Anciently, those who held by these tenures paid a small sum every fifth year into the exchequer, to be respited doing their homage or service.

By stat. 12 Car. II. this respite of homage is taken away, as a charge arising from knight-service; which is thereby likewise annulled.

RESPITE of *Execution*. See REPRIEVE.

RESPITE of *Jury*. See JURY.

RESPITED on the *Muster-Roll*, To be, in *Military Language*, is to be suspended from pay, &c.; during which period all advantages of promotion, pay, &c. are stopped. The money which is respited upon the muster-roll is accounted for by the muster-master general, and placed to the credit of the public by the paymaster general.

RESPOND, in *Ecclesiastical History*, was a short anthem sung after reading three or four verses of a chapter: after which they proceeded with the chapter. Gibson 263.

RESPONDEAS OUSTER, in *Law*, is to answer over in an action to the merits of the case: or put in a more substantial plea.

RESPONDEAT SUPERIOR, a law phrase. Where the sheriffs are removable, as in London, for insufficiency; *respondeat superior*, that is, the mayor and commonalty are to answer for them.

If a coroner of a county is insufficient, the county as his superior shall answer for him. (Wood's Inst. 83.) If a gaoler

gaoler constitutes another under him, and he permits an escape, if he be not sufficient, *respondeat superior*; and superior officers must answer for their deputies in civil actions, if they are insufficient to answer damages.

For the insufficiency of a bailiff of a franchise *respondeat superior*, that is, the lord of the franchise is to answer.

RESPONDENT, RESPONDENS, in the schools, a person who maintains a thesis in any art or science.

He is thus called, as being to answer all objections proposed by the opponent, or impugner, &c.

The respondent's business is to see whether the opposition made by the contrary party be just and legitimate; or whether some of the laws and conditions of opposition be not broken; which is called *ignoratio elenchi*. He is also to examine the moods and figures of the syllogisms, to see whether the premises be just, &c. and through the whole to answer rather by distinguish's, than by direct negation.

RESPONDENT, formed from the Latin *respondere*, to answer, q. d. *pro alio spondere*, to promise for another, in Law, a person who undertakes to answer for another; or binds himself as security for the good behaviour of another.

The respondent is to answer for the damages done by the person for whom he responds. There are four ordonnances of the kings of France, by which the citizens are expressly forbid to take servants without respondents, bound in writing.

RESPONDENTIA, in Commerce, a term applied to money which is borrowed, not upon the vessel, as in bottomry, but upon the goods and merchandize contained in it, which must necessarily be sold or exchanged, in the course of a voyage; in which case the borrower, personally, is bound to answer the contract; and he is said to take up money at respondentia.

It is enacted, by stat. 19 Geo. II. cap. 37, that all monies lent on bottomry, or respondentia, on vessels bound to or from the East Indies, shall be expressly lent only upon the ship, or upon the merchandize; that the lender shall have the benefit of salvage; and that, if the borrower has not on board effects to the value of the sum borrowed, he shall be responsible to the lender for so much of the principal as hath not been laid out, with legal interest and all other charges, though the ship and merchandize be totally lost.

Although respondentia and bottomry are of themselves a species of insurance, yet the lender has an insurable interest in his securities, and therefore may protect himself from the sea-risk by insuring them. The lender can insure only the amount of the sum lent, and the borrower has an insurable interest in the ship or goods to the amount of the surplus value above the sum lent. If either were to insure more, it would be a gaming insurance, and void by the statute 19 Geo. II. c. 37, for all above the real interest. But the usage of trade may take a case out of this rule. Upon an insurance on goods, specie and effects in the India trade, the insured may recover for money laid out for the use of the ship, and for which he charged respondentia interest, it being the usage of trade to insure in this form. A policy on bottomry or respondentia cannot be subscribed by the borrower of the money, because it is only in consideration of the sea-risk, from which he is exempt, that he agrees to pay the marine interest. If he were to become an insurer, this would be no longer a loan upon bottomry, but a cloak for usury. Respondentia and bottomry securities, though they are the subject of insurance, must be particularly and specifically described in the policy; for under the general denomination of goods, these securities cannot be insured. By 19 Geo. II. c. 32. if an under-writer become bankrupt before a loss happen, the insured may claim; and after a

loss, prove his debt under the commission, and receive his dividend, as if the loss had happened before the bankruptcy. See BOTTOMRY.

RESPONSA PRUDENTUM. See CIVIL and RESPONSE.

RESPONSALIS, in Law, he who appears for another in court at a day assigned.

Fleta makes this difference between *responsalis attornatus*, and *essoniator*, that the *essoniator* came only to allege the cause of the party's absence, be he demandant or tenant; whereas *responsalis* came for the tenant not only to excuse his absence, but to signify what trial he means to undergo, the combat, or the country.

RESPONSARY SONG, an anthem in which the choristers sing by turns.

RESPONSE, RESPONSA, *Responso*, an answer, reply, or repartee.

The word is chiefly used in speaking of the answers made to the priest, by the people, in the litany, the psalms, and other parts of the office.

It has its use, too, in speaking of the opinions or answers of the ancient jurifconsulti, when consulted on points of law.

The fifty books of the Digest are composed of *responsa prudentum*, the responses of Papinian, Ulpian, Scævola, &c. collected by Justinian; who afterwards gave them the force of laws. See CIVIL LAW.

The responses of the emperors were more properly called *rescripts*; which see.

RESPONSIONS, RESPONSIONES, a term used in the *Military Orders*, for certain pensions or charges, which the knights, or the commandries they held, paid to the order.

Such a knight templar paid a responcion of fifty pounds *per annum* to his order, on account of such a commandry.

In Rot. Parl. 9 Ric. II. the word is written *responcies*.

RESPONSORIA, responses sung in chorus by the choir, in answer to the priest in the cathedral service.

RESSAVA, in *Geography*, a town of European Turkey, in Servia; 46 miles S.E. of Belgrade.

RESSAULT, in *Architecture*, the effect of a body which either projects, or falls back, *i. e.* stands either more out or in than another; so as to be out of the line, or range, with it.

The term *ressault* is French, and but little used in English; though the want of a word of equal import pleads for its naturalization.

RESSEL, or ROESSEL, in *Geography*, a town of Prussia, in the province of Ermeland, with a castle; 50 miles S. of Königsberg.

RESSELA, a term used by Paracelsus to signify, as himself explains it, any thing that expels heat, in opposition to *assa*, which with him signifies any thing that promotes it.

RESSONS, in *Geography*, a town of France, in the department of the Oise, and chief place of a canton, in the district of Compiègne; 10 miles W.S.W. of Noyons. The place contains 1039, and the canton 9637 inhabitants, on a territory of 170 kilometres, in 23 communes.

RESSORT, or RESORT, a term purely French, yet frequently used, by our late writers, to signify the jurisdiction or authority of a court.

The word, in its popular meaning, signifies *spring*, or the force of elasticity. Hence it is also used for a jurisdiction, and the extent or district thereof; as when we say, such a thing belongs to his ressort; a judge out of his ressort has no authority. But its chief use among us is in speaking of a court or tribunal, where appeals are judged; or of a court or person who judges finally and ultimately, and whence there is no appeal.

The house of lords judge in the last resort, *en dernier ressort*. Prefidials judge in the last resort of all criminals prosecuted by the provosts of the marshals. See *DERNIER ressort*.

*RESSORT*, or *Resort*, is also used in a writ of avel, or covengeance, in the same sense as *descent*, in a writ of right.

*RESSOURCE*, or *RESOURCE*, a term purely French, yet used by English writers to denote a means or foundation of a man's recovering himself from his fall or ruin; or an after-game for the repairing of his damages.

Skinner derives the word from the French *refoudre*, *to resolve*. A resource strictly and literally expresses a means which presents itself afresh.

This merchant has credit and friends still left; he has great resources.

*REST*, *QUIES*, in *Physics*, the continuance of a body in the same place; or its continual application or contiguity to the same parts of the ambient and contiguous bodies. See *SPACE*.

Rest is either *absolute* or *relative*, as place is. See *PLACE*. Some define rest the state of a thing without motion; and hence again rest becomes either absolute or relative, as motion is. See *MOTION*.

Sir Isaac Newton defines true or *absolute* rest to be the continuance of a body in the same part of absolute and immoveable space; and *relative* rest to be the continuance of a body in the same part of relative space.

Thus, in a ship under sail, relative rest is the continuance of a body in the same region of the ship, or the same part of its cavity. True or absolute rest is its continuance in the same part of universal space, in which the ship, with its cavity and contents, are all contained.

Hence, if the earth be really and absolutely at rest, the body relatively at rest in the ship will really and absolutely move, and that with the velocity with which the vessel moves. But if the earth do likewise move, there will then arise a real and absolute motion of the body at rest; partly from the real motion of the earth in absolute space, and partly from the relative motion of the ship on the sea. Lastly, if the body be likewise relatively moved in the ship, its real motion will arise partly from the real motion of the earth in immoveable space, and partly from the relative motion of the ship on the sea, and of the body in the ship.

Thus, if that part of the earth, where the ship is, move eastward with a velocity of 10,010 parts, and the vessel be carried by the wind westward ten parts, and, at the same time, a seaman aboard walk with the velocity of one part, the seaman will be moved really and absolutely in immoveable space eastward, with 10,001 parts of velocity; and relatively on the earth, with nine parts of velocity westwards.

It is an axiom in philosophy, that matter is indifferent as to rest or motion. Hence sir Isaac Newton lays it down as a law of Nature, that every body perseveres in its state, either of rest or uniform motion, except so far as it is disturbed by external causes.

The Cartesians will have firmness, hardness, or solidity of bodies to consist in this, that their parts are at rest with regard to each other; and this rest they establish as the great nexus, or principle of cohesion, by which the parts are connected together.

Fluidity, they add, consists in a perpetual motion of the parts, &c. But the Newtonian philosophy furnishes us with much better solutions. See *SOLIDITY*, *FLUIDITY*, and *COHESION*.

Monsieur de Maupertuis asserts, that when bodies are in equilibrio, they must be so situated, that, if any small motion be impressed on them, the quantity of action resulting

will be the least possible. This he calls the law of rest, and from this law he deduces the fundamental proposition of statics. See *Mem. de l'Acad. de Berlin*, tom. ii. p. 294.

Monsieur de Maupertuis deduces the laws of percussion from the same principle. See *Quantity of ACTION*.

*REST*, *Repose*, or *Pause*, in *Poetry*, is used for the caesura, which, in Alexandrine verses, falls on the sixth syllable; and, in verses of ten or eleven syllables, on the fourth.

The rest should never fall on a monosyllable, on which the voice may not dwell: it is called rest, because the ear and the pronunciation have both a repose, or respite.

*REST*, in *Military Language*, a kind of fork to support muskets, when presented in order to fire. Sometimes these rests were armed with a contrivance called a swine's feather, which was a sort of sword-blade, or tuck, that issued from the staff of the rest, at the head: this, being placed before the musqueteers when loading, served, like the stakes placed before the archers, to keep off the cavalry. See *MUSKET*.

Rests were of different lengths, according to the heights of the men who were to use them; they were shod with sharp iron ferrils, for sticking them into the ground, and were, on the march, when the musket was shouldered, carried in the right hand, or hung upon it, by means of a string or loop tied under the head.

*REST Arms, To*, is to bring the firelock to the same position as in present arms.

*To REST upon reversed Arms*. At military funerals the arms are reversed: on which occasions, the soldiers belonging to the firing party, rest upon the butt ends of their firelocks, while the funeral service is performed, leaning with their cheeks so as to turn from the corpse; and the word of command is "Rest upon your arms reversed."

*REST*, in *Tilting Armour*. See *TILTING Armour*.

*REST*, in *Music*, is a pause, or interval of time, during which there is an intermission of the voice, or sound.

Rests are sometimes used in melody, that is, in music of a single part, to express some simple passion, or even for variety sake; but more frequently in harmony, or compositions of several parts, for the sake of the pleasure of hearing one part move on while another rests, and this interchangeably.

Rests are either for a whole bar, or more than a bar, or but for a part of a bar. When the rest is for a part, it is expressed by certain signs, corresponding to the quantity of certain notes of time; as minim, crotchet, &c.; and is accordingly called *minim-rest*, *crotchet-rest*, &c.

The characters or figures of which, see under *CHARACTERS of Music*, where the notes and corresponding rests are found together.

When any one of those characters occurs, either on a line or space, that part is always silent for the time of a minim, or crotchet, &c. Sometimes a rest is for a crotchet and quaver together, or for other quantities of time for which there is no particular note; in which case the signs of silence are not rests, but such silence is expressed by placing together as many rests, of different time, as make up the designed rest. When the rest is for a whole bar, the semibreve rest is always used. If the rest be for two measures, it is marked by a line drawn across a whole space. For three measures it is drawn across a space and a half, and, for four measures, across two spaces. But, to prevent ambiguity, the number of bars is usually written over the sign.

Some of the more ancient writers in music make these rests of different value in different species of time, *e. gr.* the character of a minim-rest, in common time, say they, expresses the rest of three crotchets in triple time; in that of the

the triples  $\frac{6}{8}$ ,  $\frac{6}{16}$ ,  $\frac{1}{8}$ ,  $\frac{1}{16}$ , it always marks a half-measure, how different foever these may be among themselves.

They add, that the rest of a crotchet in common time is a rest of three quavers in the triple  $\frac{3}{8}$ , and that the quaver-rest of common time is equal to three femiquavers in the triple  $\frac{3}{16}$ . But this variety in the use of the same character is now laid aside. Malcolm's Treat. of Music, p. 409, &c.

Franco, the inventor of musical characters for time, commonly ascribed to John de Muris, in the fourth chapter of his tract in the Bodleian library, entitled "Ars Cantus Mensurabilis," says, "as the sounds in each mood are expressed by different notes or figures, and as disant itself is as much regulated by *silence* as by sound, it will be necessary to treat not only of the signs or representatives of sounds, but of their equivalent rests or pauses."

But though Magister Franco may have invented the first time-table, consisting of full or black notes; John de Muris seems to have arranged the second time-table, consisting of void or open notes, from the maxima to the minim. And in Morley's time, the notes were multiplied and accelerated to the femiquaver, with their equivalent rests. See the *third TIME-TABLE*.

REST-Harrow, in *Botany*. See ONONIS.

RESTAUR, RESTOR, in *Ancient Customs*, the remedy or recourse which assurers have against each other, according to the date of their assurances; or against the masters, if the average arise through their default; as through ill loading, want of caulking, or want of having the vessel tight.

The word is also used for the remedy, or recourse, a person has against his guarantee, or other person, who is to indemnify him from any damage sustained. Hence *restaurant* and *restoration*. In the lower Latin they also use the words *restor* and *restaur*.

RESTAURATION, RESTAURATIO, *Restoration*, the act of re-establishing, or setting a thing in its former good estate.

Thus we say, the restoration of a minor to the possession of his effects, alienated in the time of his minority. In the French laws it is an ancient formula, used for the restoring a person to his good name, after he has been wrongfully accused and condemned.

In England we say *the Restoration* or *Restoration*, by way of eminence, for the return of king Charles II. in 1660, after the civil wars.

The 29th of May is an anniversary festival, appointed to be held in commemoration of the restoration of regal and episcopal government, by stat. 12 Car. II. c. 14.

We shall here observe, that the form of prayer for the 29th of May, as well as for the 30th of January, were of a different complexion in the reign of king Charles II. from the present, of which the reason is said to be this: the parliament and other leading men, who were active in his restoration, and who had been concerned in opposing his father's measures, would not be called traitors; and required that a distinction should be made between the commencement of the war and the conclusion of it; they would not suffer the first opposition made to the measures of that unhappy prince to be styled rebellion, though they disapproved of the abolition of regal government which ensued.

And accordingly the offices for these two solemnities were drawn up, without any reflection on the first authors or promoters of the opposition, and, in general, breathe more a spirit of piety than of party, of humiliation than of revenge; and, throughout, are modest, grave, decent, sensible, and devout. King James II. altered these forms, and king William did not venture to reduce them to their primi-

tive state; and so they have continued, with very little variation, to this day.

There is no order in either of these offices for a sermon or homily on this day; and in the office of Charles II., there is no direction for a sermon or homily on the 30th of January; but by the office of James II. it is required that on the said 30th day of January shall be read the first and second parts of the homily against disobedience and wilful rebellion, or else the minister shall preach a sermon of his own composing upon the same argument. The 29th of May is not a holiday in any of the law-offices, and consequently no officer can take an extraordinary fee for business done on that day. 7 Term Rep. 163.

By 12 Car. II. c. 14. it is enacted, to the end that all persons may be reminded of their duty on the 29th of May, and be the better prepared to discharge the same with that piety and devotion which become them, that every minister shall give notice to his parishioners publicly in the church at morning prayer, the Lord's day next before such 29th day of May, for the due observation of the said day, and shall then likewise publicly and distinctly read this present act to the people.

RESTAURATION, in *Architecture*, the act of repairing all the parts of a building gone to decay, either through the course of time, or other injuries; in such manner, as that it is not only re-established in its first form, but considerably augmented.

It is evident, from the plinths of the Corinthian columns of the Pantheon (which are almost wholly under ground), that the pavement of this temple is only a restoration made in the time of Septimius Severus. Daviler.

The temple of Concord, behind the Capitol at Rome, having been burnt long after it was built, and having angular bases different from the rest, seems to have been restored from the ruins of several ancient buildings.

RESTAURATION, in *Sculpture*, is the repairing of a mutilated statue, &c. See REPAIRING.

Most of the antique statues have undergone a restoration; as the Farnese Hercules, the Faunus in the Villa Borgnese at Rome, the Wrestlers in the gallery of the great duke of Florence, the Venus of Arles, in the gallery at Versailles. But these restorations have all been made by the ablest sculptors. Daviler.

RESTIACEÆ, in *Botany*, a natural order of plants, first separated from the *Junci* of Jussieu by Mr. Brown, Prodr. Nov. Holl. v. 1. 243, and named from one of its chief genera; see RESTIO. The characters are these.

*Perianth* unconnected, deeply divided into from two to six segments, or rather of so many leaves; rarely wanting. *Corolla* none. *Stamens* definite, from one to six; when they are two or three, in a four or six-cleft perianth, they are opposite to its inner leaves. *Germen* of one or several cells, each cell containing one pendulous seed, except in *Xyris*, whose seeds are numerous. *Pericarp* either capsular, or amentaceous. *Seeds* inverted. *Albumen* shaped like the seed. *Embryo* lenticular, situated in the lower end of the seed, opposite to its scar, at the outside of the albumen.

*Plants* herbaceous or somewhat shrubby, almost all exotic with respect to Britain, and even Europe. *Leaves* simple, narrow, in some cases wanting. *Stems* naked, but often furnished with sheathing scales, cloven at one side, imbricated, or equitant, at the other. *Flowers* for the most part aggregate, spiked or capitate, separated by *bractæas*, the *stamens* and *styles* generally in separate individuals.

This order is distinguished from the *Junci*, by having the embryo external, and contrary to the scar; from the *Commelineæ* of Brown, by the figure of that part, and its not being

being enclosed in the albumen. Those genera which have the habit of the *Cyperaceous* order, are well distinguished from it by the sheaths of the stem being split, not undivided. *Xyris*, though referred to the *Restiacea*, and scarcely more akin to any other tribe, still differs widely from the rest of this order; especially in the petal-like inner segments, or leaves, of its perianth; the claws bearing the stamens at their summits; and the numerous seeds. See Observations on the generic character of RESTIO.

The New Holland genera of the present order are *Restio*, *Leptoradia*, *Lyginia*, *Anarthria*, *Loxocarya*, *Leptocarpus*, *Chatanthus*, *Hypolæna*, *Aphelia*, *Devauxia*, *Alepyrum*, *Eriocaulon* and *Xyris*.

RESTIARIA, a name given by Rumphius, in his *Herbarium Ambonense*, v. 3. 187, to two or three different shrubs, on account of their fitness for ropes, or cordage; *restiarius* being a sort of base Latin word for a rope-maker. The first of these, *R. alba*, t. 119, is a very well-marked genus, for which the name might have been retained; but Linnæus, in his *Supplementum*, has called that genus *Commerstonia*, after the example of Forster, in his *Nova Genera* t. 22. (See *COMMERSTONIA*.) Of the second, termed *R. nigra*, Rumphius gives no plate. We shall speak of it presently. The third he has called *Perticaria*, from *pertica*, a staff or pole; which name is also a synonym of the other two. Nothing is known respecting the flowers, or generic character, of this last. Loureiro has adopted the name *Restiaria*, for a plant which he supposes the same with the *nigra* of Rumphius, but of which he knew the female flowers only. The following is his account of it. Loureir. Cochinch. 639. Class, *Diœcia*; Order unknown, as well as the Nat. Ord.

Gen. Ch. Male flowers unknown.

Female on a separate plant. *Cal.* Perianth superior, oblong, capsular; limb in five deep, lanceolate, spreading segments. *Cor.* none. *Pist.* Germen inferior, oblong; style none; stigma concave. *Peric.* Capsule calycine, ovate-oblong, somewhat tapering at each end, five-ribbed, hairy, with two cells and two valves. *Seeds* numerous, compressed, roundish, with a long, thin, membranous, linear wing at each side.

Ess. Ch. Male . . . . .

Female, Calyx five-cleft, capsular, superior. Corolla none. Stigma concave. Capsule with five ribs, two cells, two valves, and numerous winged seeds.

Obs. We do not profess to understand Loureiro's expressions of *perianthium capsulare*, and *capsula calycina*, but give them as we find them, having no knowledge of the plant itself. De Theis suggests its affinity to *Gouania*.

1. *R. cordata*. Lour. (*R. nigra*; Rumph. Amb. v. 3. 188?)—Native of the woods of Cochinchina. A large shrub, with a reclining stem, and climbing branches, destitute of tendrils or thorns. *Leaves* opposite, heart-shaped, rugose, hairy, entire, large. *Flowers* in lax, axillary panicles, with long general as well as partial stalks. The bark is tough and porous, splitting into long strips, of which torches are made, and which serve also for caulking of vessels. The generic name was adopted by Loureiro, because of the fitness of the stems and branches for cordage.

RESTINCLIERS, in *Geography*, a town of France, in the department of the Herault; nine miles N.E. of Montpellier.

RESTINCTION, RESTINCTIO, in *Chemistry*, the quenching of a metal or mineral in some liquor, in order either to correct or to exalt it; by giving it some new quality, power, &c.

RESTING GROUND, in *Gardening*, the means of re-

freshing it, and of restoring its fertility by the omission of culinary crops, and the cultivation of such as have this tendency, or by any other methods which may have the same effect. It is a sort of management which is principally accomplished in two different ways: the former of which is that of sowing a certain portion of it, annually, with corn and some sort of grass seeds, suffering it to continue under the latter of them for three or more years, as in arable field lands, in order that it may then be broken up again. This is a very beneficial method, but not much practised, except by market-gardeners, who employ these two crops in feeding and foddering their cattle. When made use of in other ways, as in other gardens, great care should be taken that the grass never runs up to seed, as is sometimes the case in market-gardens, but in all other particulars the practice may be entirely the same. In this way of proceeding, by sowing and laying down a certain quantity of ground every year, the same extent may be broken up, which will, of course, afford so much fresh soil annually, upon which such garden crops as answer best on newly broken up land, may be put in and raised, as those of onions, carrots, turnips, and a great many other kinds.

The latter of the above modes of managing the business, is, however, better adapted to gardens in general, as being more suited to the nature of their culture. It was, probably, first suggested by the author of the "Scotch Forcing Gardener;" and is extremely well suited to produce the same effects and advantages as that which has been already noticed; and it may, indeed, in some cases, be combined with it, or used conjointly, with great benefit; as by such means much fresh surface soil will be yearly at the command of the gardener. The manner of performing it is this; after taking three culinary crops off from the first surface, the ground is to be trenched over three spits deep, by which the bottom and top parts are reversed, and the middle part still remains in that situation; then three similar crops are to be taken off from this surface, and the ground afterwards trenched two spits deep, by which means the top becomes the middle, and the middle the top; three of the same kind of crops being here also taken off from this surface, and then the ground trenched three spits again, that part which was last the middle, and now the top, becomes the bottom; and that which is now the bottom, and was the surface at first, now becomes the surface again, after having had six years' rest. By this alternate manner of proceeding, one time trenching three spits deep, and the other two, the surface will constantly be changed, and will rest six years, while it is three years productive. On which account there will be continually new ground and soil in the garden for the growth of healthy culinary vegetables; and besides, much less manure will be wanted than where the soil is shallow, and the same surface constantly under culinary crops.

Proper and careful modes of cropping, as well as other kinds of management, may likewise, in many cases, contribute greatly to the same intention.

RESTING Land, in *Agriculture*, the means of keeping it without any sort of crop, or only under particular kinds, in the view of restoring its fertility. This is done in the practice of naked fallowing, as well as that of cultivating green crops by way of a fallow, and by laying land down to the state of grass, in order to its being afterwards broken up for grain crops. See FALLOW and FALLOWING, also GREEN CROPS, and LAYING down to grass.

RESTIO, in *Botany*, from *restis*, a cord, because many of the genus serve, at the Cape of Good Hope, where they abound, to make ropes, baskets, &c. *Restio* is properly a person who fells cord, or ropes. ELEGIA, see that article,

is nearly related in habit, as well as characters, to the present genus, and was finally united to it by Linnæus, contrary to Thunberg's opinion.—Linn. Syst. Nat. ed. 12. v. 2. 735. Schreb. 676. Mart. Mill. Dict. v. 4. Ait. Hort. Kew. v. 5. 368. Brown Prodr. Nov. Holl. v. 1. 244. Thunb. Dill. May 17. 1788. Rottb. Gram. 1. Juss. 44. Labill. Nov. Holl. v. 2. 77. Lamarek Illustr. t. 804. (Chondropetalum; Rottb. Gram. 10. Calorophus; Labill. Nov. Holl. v. 2. 78.)—Class and order, *Dioecia Triandria*. Nat. Ord. *Calamariæ*, Linn. *Junci*, Juss. *Restiæ*, Brown.

Gen. Ch. Male, *Cal.* Catkin ovate or oblong, many-flowered; its scales coriaceous, imbricated, keeled. Perianth compressed, of four or six, nearly equal leaves; two of the outer ones boat-like, the third flat; the three innermost lanceolate, thinner, one of them broader than the rest. *Cor.* none, except the three inner leaves of the calyx be so considered. *Stam.* Filaments three, sometimes but two; anthers oblong, simple, peltate.

Female, on a separate plant, *Cal.* and *Cor.* as in the male. *Pist.* Germen superior, triangular; style one, deeply divided into two or three parts; stigmas feathery. *Peric.* Capsule with two or three lobes, and as many cells, bursting at the prominent angles. *Seeds* solitary, somewhat oval.

Obf. *Chondropetalum* of Rottboll differs from the rest of the species, in having the inner segments of the calyx longer, and of a cartilaginous texture. This difference, and the still more remarkable one in *Xyris*, between the outer and inner segments of the calyx, might surely authorize us to call the three latter a corolla, in both these instances.

Ess. Ch. Male, Catkin imbricated. Perianth of four or six leaves, shorter than the scales of the catkin, destitute of internal scales. Corolla none. Anthers peltate.

Female, Catkin and Perianth like the male. Stigmas two or three. Capsule of two or three lobes, and as many cells, bursting at the angles. Seeds solitary.

The plants of this genus have a hard, rigid, smooth, rushy habit. The root is scaly, creeping, and perennial. Stems rushy, simple or branched, leafless, sheathed with scales split at one side. Catkins either solitary, spiked or panicle. Mr. Brown observes, that the scar of the seed is naked in the New Holland species, but in those from the Cape of Good Hope it is bordered. Several things which Thunberg and Rottboll have referred to *Restio*, are by Mr. Brown removed to other genera; see LEPTOCARPUS and THAMNOCHORTUS. This author defines 24 New Holland species, in his Prodromus. How many are found at the Cape, we have no means of determining, because of the uncertainties respecting their generic characters, which we have not materials to remove. The following may serve as examples.

#### Section 1. *Stem simple.*

*R. tetlorum*. Thatch Rope-grafs. Linn. Suppl. 425. Ait. n. 1. (Chondropetalum deustum; Rottb. Gram. 10. t. 3. f. 2.)—Stem simple. Leaves none. Catkins racemose, mostly leaning one way, drooping, bracteated, roundish, triangular. Gathered by Thunberg at the Cape, from whence Mr. Maflon sent living plants to Kew, in 1793. They are kept in the greenhouse, blossoming in May and June. The root is perennial, small and tapering, throwing out horizontal scaly shoots. Stems several, a foot and half high, erect, very straight, round, slender, smooth, unbranched, with short taper-pointed sheaths at the joints. Cluster terminal, compound, about two inches long, variegated with black, or dark purple, and brown. The stems are used for thatching, for which their hard rigid nature is well calculated; nor is this thatch disturbed by the very high winds that prevail in southern Africa. *Thunberg*.

*R. scruuus*. Pendulous-headed Rope-grafs. Linn. Suppl.

425. Thunb. Rest. n. 4. t. 1. f. 2.—Stem simple. Leaves none. Catkins turbinate, pendulous, on capillary stalks. Native of the Cape, on hills about the Table mountain. The stem is slender, jointed and smooth, two feet high, or more, with scales at the joints, but no leaves. Catkins three, four, or five, at the top of each stem, about the size of a pea, brown, obtuse, tapering at the base, pendulous, each supported by a capillary stalk. Scales obtuse, with a small point.

*R. dichotomus*. Fork-leaved Rope-grafs. Linn. Syst. Nat. ed. 12. v. 2. 735. Rottb. Gram. 2. t. 1. f. 1. (Schoenus capensis; Linn. Sp. Pl. 64?)—Stems simple. Leaves repeatedly compound, with awl-shaped leaflets. Panicle drooping. Catkins oblong. Scales taper-pointed. Common at the Cape. Stems several, a foot or more in height, bearing a few sheaths. Leaves, or, as some call them, barren stems, much shorter than the flowering stems, slender, twisted, branched, with a sheath at each joint; their ultimate subdivisions awl-shaped, channelled. Panicles at the top of each stem, of 10 or 12 drooping oblong catkins, whose scales are of a shining brown, and very finely pointed.

#### Section 2. *Stem branched.*

*R. verticillaris*. Horse-tail Rope-grafs. Linn. Suppl. 425. Thunb. Rest. n. 22. t. 1. f. 7.—Branches whorled, jointed; with ovate scales. Panicle compound, close.—Found about the banks of rivers at the Cape. Stem five or six feet high, resembling an *Equisetum* in its copious, slender, whorled branches, from every joint; bearing numerous ovate, taper-pointed, small scales. We confess ourselves unable to draw a line between these branches, and what we have termed leaves in the last-described species, except that the latter are mostly, if not entirely, radical, and these grow from every joint of the stem. The catkins are extremely small and numerous, in branched, repeatedly compound, dense clusters.

*R. tetraphyllus*. Four-leaved Rope-grafs. Labill. Nov. Holl. v. 2. 77. t. 226, 227. Brown n. 24.—Stems semi-cylindrical, with blunt sheaths. Leaflets setaceous. Panicle terminal, compound. Catkins nearly globose. Scales pointed. Male flowers six-cleft; female four-cleft.—Native of New South Wales and Van Diemen's island. Stems numerous, stout, three feet high, with a few leafy branches in the upper part, whose ultimate divisions are bristle-shaped. Catkins stalked, ovate in the female plant, nearly globose in the male. The perianth of the female flowers has but four leaves, that of the male six.

RESTITUTION, RESTITUTIO, in *Physics*, the returning of elastic bodies forcibly bent to their natural state, by some called the *motion of restitution*. See ELASTICITY.

Contraction being the proper and natural action of muscular fibres, some authors ascribe dilatation to a motion of restitution; but the expression, as well as the idea, is very faulty.

RESTITUTION, in the moral and legal sense, is the act of restoring a person to his right, or of returning something unjustly taken or detained from him.

Restitution is reducible to commutative justice; and till it be made, the casuists determine the party all the while guilty of theft.

The illegal incumbents of benefices are condemned to a restitution of the fruits of the benefices. In the Romish church, usurers, &c. are obliged to a restitution of their ill-gotten goods; otherwise the priest has no authority to give them absolution.

RESTITUTION in *Blood*. See CORRUPTION of *Blood*, ATTAINDER, and PARDON.

RESTITUTION of *Conjugal Rights*. See CONJUGAL Rights.

RESTITUTION of *Stolen Goods*, in *Law*, is allowed to the prosecutor, on a conviction of larciny, by stat. 21 Hen. VIII. c. 11. For, by the common law, there was no restitution of goods upon an indictment, because it is at the suit of the king only; and therefore the party was forced to bring an appeal of robbery, in order to have his goods again. But it being considered that the party, prosecuting the offender by indictment, deserves as much encouragement as he who prosecutes by appeal, this statute was made, which enacts, that if any person be convicted of larciny by the evidence of the party robbed, he shall have full restitution of his money, goods, and chattels, or the value of them out of the offender's goods, if he has any, by a writ to be granted by the justices. And this writ of restitution shall reach the goods so stolen, notwithstanding the property of them is endeavoured to be altered by sale in market overt; or else, without such writ of restitution, the party may peaceably retake his goods, wherever he happens to find them, unless a new property be fairly acquired therein; or, lastly, if the felon be convicted and pardoned, or be allowed his clergy, the party robbed may bring his action of trover against him for his goods, and recover a satisfaction in damages; but such action lies not before prosecution, for so felonies would be made up and healed. See RECAPTION.

RESTITUTION of *Temporalties of Bishops*. See TEMPORALITIES, and RESTITUTIONE *Temporalium*.

RESTITUTION in *Integrum*, is used for what is otherwise called *rescissio*.

Religious obtain restitution against their vows, *i. e.* they are freed from their obligation, when they protest against them within five years of their profession.

In the history of Germany for the seventeenth century, the first day of January, 1624, is called the *term of restitution*; because by the peace of Munster, then concluded, the Lutheran and Calvinist princes were obliged to restitute, or restore what they had taken from the Roman Catholic churches in their territories till that day.

By the peace of Westphalia in 1648, the restitution-edict was abrogated, and both the contending parties confirmed in the perpetual and uninterrupted possession of whatever they had occupied in the beginning of the year 1624. And all the articles agreed upon by this peace were confirmed and ratified, in the year 1650, at Nuremberg.

RESTITUTION of *Medals*, or *Restituted Medals*, is a phrase used by antiquaries, for such medals as were struck by the emperors, to renew or retrieve the memory of their predecessors.

Hence it is, that in several medals we find the letters *REST*. Claudius was the first who began this practice, by striking afresh several medals of Augustus. Nero did the same; and Titus, after the example of his father, struck restitutions of most of his predecessors. Some, however, have maintained that the restituted medals of Claudius and Nero are modern and spurious, and that the practice began under Titus.

Gallienus struck a general restitution of most of the preceding emperors in two medals, the one bearing an altar, the other an eagle, without the *rest*. F. Joubert chooses rather to call them *conversations* than restitutions, as being done quite anew. These were designed to preserve the remembrance of the consecration of those emperors in honour of whom they were struck; and they have all the same legend on the reverse, *viz.* CONSECRATIO.

RESTITUTIONE *extrañi ab ecclesia*, in *Law*, a writ

anciently granted for the restoring a man to the church, or sanctuary, from which he had been forced away.

RESTITUTIONE *Temporalium*, a writ which lies where a man is elected and confirmed bishop of a diocese, for the recovery of the temporalities, or barony, of the said bishopric.

It is directed from the king to the escheator, or rather sheriff of the county.

RESTIVE, or RESTY, a term applied to a horse, &c. that stops, or runs back, instead of advancing forwards.

In the manege, a restive horse is a rebellious, refractory, ill-broken horse, which only goes where it will, and when it will. The word is formed from the Latin *restivus*, which signifies the same thing. (See RAMINGUE.) A horse of this sort, who has been too much constrained and tyrannized over, should be treated with the same lenity as a young colt. The spurs are improper to be used to either; instead of which a switch should be used, in order to drive him forward, as he will be thus less alarmed; because the spurs surprize a horse, abate his courage, and are more likely to make him restive than oblige him to go forward, if he refuses to do so. There is likewise another method to punish a restive horse, which is to make him go backward the moment he begins to resist. These corrections generally succeed; but the general rule is to push and carry your horse forward, whenever he refuses to advance, and continues in the same place, and defends himself either by turning or flinging his croupe on one side or the other; and, for this purpose, nothing is so efficacious as to push him forward vigorously. Berenger's Horsemanship, vol. ii. p. 29, &c. See RIDE.

RESTOR. See RESTAUR.

RESTORATION. See RESTAURATION.

RESTORATION, in *Theology*, a term applied by those who maintain the doctrine of the final happiness of all mankind, to the recovery of transgressors from a state of guilt and misery to pardon and felicity, in consequence of the penal discipline which they are doomed to endure in a future world. See this doctrine discussed under the article HELL.

RESTORATION *Cove*, in *Geography*, a bay on the west coast of North America, in Burke's canal, so called by Vancouver, from the 29th of May, the day of its discovery. Among the skins brought to sale at this bay were those of the animal which produces the wool, of which the garments worn by some of the Indians are made. Their length, exclusively of the head and tail, was 50 inches; and their breadth, exclusively of the legs, was 36 inches. All the skins that were brought to captain Vancouver were white, or rather of a cream colour. The pelt was thick, and of a fine texture; but from their state of mutilation, the species of animals to which they belonged could not be ascertained. The women, who appeared to be of the greatest importance, were adorned by an horizontal incision about three-tenths of an inch below the upper part of the under lip, extending from one corner of the mouth to the other; and in this slit was fixed a piece of wood, confined closely to the gums of the lower jaw, and projecting by its external surface horizontally. These wooden ornaments were of an oval form, and resembled a small oval platter or dish, concave on both sides: the smallest of them was about 2½ inches, and the largest 3¾ inches long, and 1½ inch broad; the others decreased in breadth in proportion to their length. The clothing of the natives here consisted either of the skins of the sea-otter, or of garments made of the pine-bark, into which was neatly wrought some of the fur of the sea-otter, and their sides and bottoms were decorated with various colours. In this they use only woollen yarn, very fine, well spun, and dyed for that purpose, particularly with a very

lively and beautiful yellow. N. lat.  $52^{\circ} 1'$ . E. long.  $232^{\circ} 20'$ .

**RESTORATION Island**, a small island in the South Pacific ocean, near the east coast of New Holland, discovered by captain Bligh in 1789. S. lat.  $12^{\circ} 39'$ .

**RESTORATION Point**, a cape on the west coast of Vashon's island. N. lat.  $47^{\circ} 30'$ . E. long.  $237^{\circ} 46'$ .

**RESTORATIVE**, in *Medicine*, such substances both in the way of food, drink, and medicines, which are calculated to restore the vigour of the constitution, after the cessation of acute diseases, after violent hæmorrhages, fatigue, watching, or want of food. These of course comprehend the most nutritious parts of animal substances, jellies, broths, &c.; and the vegetable starches, arrow-root, sago, &c. with milk, rice, and other light nourishment. The restorative medicines will be selected from the bitter and aromatic vegetables, and some of the metallic salts, especially those of iron; their principal use being to give tone and vigour to the digestive organs, and thus enable them to extract and digest the nutriment, which the food affords.

**RESTOUN**, in *Geography*, a town of Syria, anciently called "Arethusa;" 12 miles S.E. of Hamah.

**RESTOW**, a town of Austrian Poland, in Galicia; 72 miles W. of Lemberg.

**RESTRAINING STATUTE**. See **REMEDIAL**.

**RESTRAINING Statute of Leases**. See **LEASES by Statute**.

**RESTRAINT** is when an action is hindered, or stopped, contrary to volition, or the preference of the mind.

**RESTRICTION**, the act of modifying, limiting, or restraining a thing to narrower bounds.

General laws always bear some restriction. In contracts it is usual to have *restrictive clauses*, which bind the covenants down to certain bounds.

**RESTRICTION, Mental**. See **RESERVATION**.

**RESTRICTION**, among *Logicians*, is understood of the limiting a term, so as to make it signify less than it usually does.

In which sense the name philosopher is restrained to Aristotle; Great, to Alexander; City, to Rome, &c.

**RESTRICTIVE PROPOSITION**. See **PROPOSITION**.

**RESTRICTIVE Suture**. See **SUTURE**.

**RESTRINGENT**, in *Medicine*. See **ASTRINGENT**.

**RESTY**. See **RESTIVE** and **RIDE**.

**RESULT**, what is gathered from a conference, an inquiry, meditation, discourse, or the like; or the conclusion and effect thereof.

The usual result of disputes, Mr. Bayle observes, is, that each person remains more attached to his own opinion.

**RESULTING USE**, in *Law*. See **USE**.

**RESUMMONS**, **RESUMMONITIO**, a second summons or calling a man to answer an action, where the first summons is defeated, or suspended, by an accident; as the death of a party, &c.

**RESUMPTION**, **RESUMPTIO**, in a law-sense, signifies the taking again into the king's hands such lands or tenements as before, upon false suggestions, or other error, he had delivered to the heir, or granted, by letters patent, to any man.

**RESUMPTION**, in the *Schools*, a summary repetition, or running over, of an argument, or of the substance of it, in order to refute it.

**RESUMPTION** is also used by *Logicians* for the reduction of some figurative or quaint proposition, to a more intelligible and significant one.

**RESUMPTIVE**, in *Pharmacy*, an epithet given to a

kind of unguent, used to recruit and restore arid languishing constitutions, and to dispose the dry bodies to receive nourishment. It is called in Latin *unguentum resumptivum*.

**RESUPINATUM FOLIUM**, in *Botany*, a reversed leaf, has its proper under side turned uppermost, as in *Pbarus latifolius*, and *Alstroemeria pelegrina*. See **LEAF**.

**RESUPINATUS FLOS**, a reversed flower, is so circumstanced, that what, according to analogy, ought to be its upper side, is really the under. Of this *Lavandula*, Lavender, is an example, the longer lip of its corolla being uppermost, while the other, with the stamens and style, are downwards.

**RESURRECTION**, **RESURRECTIO**, *Resuscitation*, the act of returning to a new or second life, after having been dead.

The great argument for the truth of Christianity, and that urged with the most force and conviction for the same, is drawn from the resurrection of our Saviour. The circumstances of it are such as almost admit of a demonstration; which has accordingly been attempted on the strict principles of geometricians. See **DITTON** on the Resurrection.

The records of the fact of our Lord's resurrection are contained in the four gospels of St. Matthew, St. Mark, St. Luke, and St. John; and though the accounts given by these historians have been charged with some discrepancies and contradictions, the difficulties occasioned by them admit of a satisfactory solution. Among those who have made attempts for this purpose, Mr. Gilbert West (ubi infra) is entitled to our particular notice. With this view, he states the several incidents of this wonderful event, according to the order in which they seem to have arisen. He premises with observing, that our Saviour Christ was crucified on a Friday (the preparation, or the day before the Jewish Sabbath); gave up the ghost about three o'clock in the afternoon of the same day; and was buried that evening, before the commencement of the Sabbath, which, among the Jews, was always reckoned to begin from the first appearance of the stars on Friday evening, and to end at the appearance of them again on the day we call Saturday. He adds, that, some time, and most probably towards the close of the Sabbath, after the religious duties of the day had terminated, the chief priests obtained of Pilate, the Roman governor, a guard to watch the sepulchre, till the third day was past; pretending to apprehend that his disciples might come by night, and steal away the body, and then give out that he was risen, as he had predicted while he was yet alive. Accordingly a guard was set, the sepulchre made sure, and, to prevent the soldiers themselves from conniving with the disciples, a seal was put upon the stone which closed up the entrance of the sepulchre.

Some have objected to the evangelical statement of the time that elapsed between our Lord's death and resurrection; and they say, that the resurrection happened a day sooner than the prediction imported. But in the "Trial of the Witnesses," it is alleged, that the objection is founded upon a mistake of a mode of speaking, common to the Jews and other people; who, when they name any number of days and years, include the first and the last of the days or years to make up the sum. Christ, alluding to his own resurrection, says, "In three days I will raise it up." The angels report his prediction thus: "The Son of man shall be crucified, and the third day rise again." Elsewhere it is said, "after three days;" and again, that he was to be in the bowels of the earth "three days and three nights." These expressions are equivalent to each other; for we always reckon the night into the day, when we reckon by so many days. If you agree to do a thing ten days hence, you stipulate

## RESURRECTION.

stipulate for forbearance for the nights as well as days; and, therefore, in reckoning, two days, and two days and two nights, are the same thing. That the expression, "after three days," means inclusive days, is proved by Grotius in Matth. xxvii. 63, and others. The prediction, therefore, was that he would rise on the third day. Now, he was crucified, as we have already stated, on Friday, and buried; he lay in the grave the whole of Saturday, and rose early on Sunday morning. But as the objectors say, he ought not to have risen till Monday: let us try what the use of common language requires to be understood, in a like case. Suppose you were told that your friend sickened on Friday, was let blood on Saturday, and the third day he died: what day would you think he died on? If you have any doubt about it, put the question to the first plain man you meet, and he will resolve it. The Jews could have no doubt in this case; for so they practised in one of the highest points of their law. Every male child was to be circumcised on the eighth day. How did they reckon the days? The day of the birth was one, and the day of the circumcision another; and though a child was born towards the very end of the first day, he was capable of circumcision on any time of the eighth day. And, therefore, it is not new nor strange, that the third day, in our case, should be reckoned into the number, though Christ rose at the very beginning of it. It is more strange to reckon whole years in this manner; and yet this is the constant method observed in Ptolemy's canon, the most valuable piece of ancient chronology, next to the Bible, now extant. If a king lived over the first day of a year, and died the week after, the whole year is reckoned to his reign.

The order of the incidents our author conceives to have been as follows. Very early on the *first* day of the week (the day immediately following the sabbath, and the *third* from the death of Christ), Mary Magdalene and the other Mary, in pursuance of the design of embalming the Lord's body, which they had concerted with the other women who attended him from Galilee to Jerusalem, set out, in order to take a view of the sepulchre, just as the day began to break; and about the time of their setting out "there was a great earthquake," &c. (Matth. xxviii. 2-4.) During the amazement and terror that occurred, Christ came out of the sepulchre; and the keepers recovered from their trance and fled, when an angel, who till this time sat upon the stone, quitted his station on the *outside*, and entered *into* the sepulchre; and probably disposed the linen clothes and napkin in that order in which they were afterwards found, and observed by John and Peter. Mary Magdalene, in the mean while, and the other Mary, were still on their way to the sepulchre, where, together with Salome (whom they had either called upon, or met as they were going), they arrived at the rising of the sun. And as they drew near, "they said among themselves, Who shall roll us away the stone from the door of the sepulchre? for it was very great:" and they themselves (the two Marias at least) had seen it placed there two days before, and seen with what difficulty it was done. But whilst they were deliberating (for it does not appear that they knew any thing of the guard), "lifting up their eyes," being yet at some distance, they perceived it *was* already rolled away. Alarmed at so extraordinary and so unexpected a circumstance, Mary Magdalene, concluding that, as the stone could not have been moved without a great number of hands, it must have been rolled away with some design; and that this design could have been no other but to remove the Lord's body; and being convinced by appearances that this was the case, ran immediately to inform Peter and John of what she had seen, and what she suspected;

leaving Mary and Salome there, so that, if Joanna and the other women should come in the mean time, they might acquaint them with their surprize at finding the stone removed, and the body gone, and of Mary Magdalene's running to inform the two above-mentioned apostles of it. While she was going on this errand, Mary and Salome went on and entered into the sepulchre; and there saw an angel "sitting on the right side," &c. (Mark, xvi. 5-8.) After the departure of Mary and Salome came John and Peter, who, having been informed by Mary Magdalene, that the body of the Lord was taken away out of the sepulchre, and that she knew not where they had laid him, "ran both together to the sepulchre," &c. (John, xx. 4-17.) After the appearance of Christ to Mary Magdalene, to whom, as St. Mark says expressly, he appeared first, the other Mary, and Salome, who had fled from the sepulchre with such terror and amazement, that "they said not any thing to any man," (Mark, xvi. 8.), that is, as the expression may be understood, had not told the message of the angel to some (probably John and Peter, who were running with Mary Magdalene to the sepulchre, about the time that these women were flying from it, and whom in their fright they might not immediately recollect), whom they met, and to whom they were directed to deliver it, were met on their way by Jesus Christ himself, who said to them, "All hail!" &c. (Matth. xxviii. 9, 10.) These several women, and the two apostles, being now gone from the sepulchre, "Joanna, with the other Galilean women, and others with them," &c. (Luke, xxiv. 1-9, 11.), Peter, who, upon the report of Mary Magdalene, had been at the sepulchre, had entered into it, and, with a curiosity that bespoke an expectation of something extraordinary, and a desire of being satisfied, had observed that the *linen clothes* in which Christ was buried, and the *napkin that was about his head*, were not only left in the sepulchre, but carefully *wrapped up*, and laid in *several places*, and who, from these circumstances, might begin to suspect, what his companion St. John from the same circumstances seems to have believed:—Peter we say, hearing from Joanna, that she had seen a vision of angels at the sepulchre, who had assured her that Christ was risen, starting up, ran thither immediately; and knowing that the angels, if they were *within* the sepulchre, might be discovered without his *going in*, he did *not*, as before, *enter in*, but *sloping down*, looked so far in as to see the *linen clothes*; and "departed, wondering in himself at that which was come to pass." (Luke, xxiv. 12.) And either *with* Peter, or *about that time*, went some other disciples, who were present when Joanna, and the other women, made their report; "and found it even so as the women had said."—"The same day, two" of the disciples "went to a village called Emmaus," &c. (Luke, xxiv. 13-35.) Such, according to Mr. West, is the order in which the several incidents above related appear to have arisen: and he concludes, that by this order, in which all the different events naturally and easily follow, and, as it were, rise out of one another, the narration of the evangelists is cleared from all confusion and inconsistency; and, moreover, the proof of the resurrection is better established by thus *separating* the women into two or more divisions, than upon the contrary supposition, which brings them *all together* to the sepulchre; for, in the last case, instead of *three different* appearances of angels to the women, and *two* of Jesus Christ, we should have but *one* of each; whereas, in the former, there is a train of witnesses, a succession of miraculous events, mutually strengthening and illustrating each other, and equally and jointly concurring to prove one and the same fact:—a fact, which, as it was in its own nature more astonishing, and in its consequences of

## RESURRECTION.

the utmost importance to mankind, required the fullest and most unexceptionable evidence. Never, says our author, was a fact more fully proved; and in stating this proof, with a brevity corresponding to our limits, and yet, we trust, with a clearness answerable to the importance of the subject, we shall avail ourselves of the luminous arrangement which our author has made of the principal arguments that establish the interesting fact of our Lord's resurrection, and that rendered it credible to the apostles and first disciples; and by means of their testimony to persons of countries and ages remote from those in which it occurred. In its reference to the conviction of the apostles and first disciples, the *first* object of consideration comprehends the characters and dispositions of the persons who were themselves to be convinced, and who were to be witnesses of the resurrection to the world in general; the *second* includes the manner, *i. e.* the method and order in which the several proofs were laid before them; and the *third* is the matter of the evidence. The knowledge of the character and disposition of the apostles and disciples, for whose conviction the proofs of the resurrection were primarily designed, is necessary to evince their aptitude and their sufficiency for this purpose, and will serve to shew us, that the manner in which they were adduced, and the matter, or facts, of which they consisted, were selected with consummate wisdom. The apostles and first disciples were, for the most part, persons of low birth and mean occupations, unaccustomed to abstract reasoning and deep inquiry, and strongly possessed with the national prejudices of the Jewish religion, as it was then taught by the Scribes and Pharisees. Although it appears from many passages in the gospel history, that they were convinced by the numerous miracles which Jesus of Nazareth performed, and by the accomplishment of many prophecies in the history of his life, of his being the promised and expected Messiah; yet they were deluded by the notion prevalent among their brethren, the Jews, that the Messiah would be a temporal prince, a redeemer and ruler of Israel, who should never die. Our Saviour, in many of his discourses, laboured to undeceive them; but their prepossessions and errors were so deeply rooted, that all his efforts for this purpose proved ineffectual. He had, indeed, most circumstantially foretold his own sufferings, death, and resurrection: but it sufficiently appears, that they did not understand these predictions, until some time after their accomplishment. As, in their opinion, immortality and temporal dominion were the characteristics of the Messiah, the sufferings and death of Jesus must have convinced them, before his resurrection, that he was not the Messiah, or that person in whom they had trusted as the Redeemer and king of Israel. When he actually died according to his prediction, and his enemies seemed to have obtained a complete triumph over him, their minds must have been agitated by prejudice, doubt, perplexity, despair, and terror. The evidence, therefore, that was adapted to recover them from this state, must, in the *manner* of its being presented to them, as well as in its own nature, be of a peculiar kind: otherwise it could not have served the purpose of converting them from being incredulous and ready to desert their Master, into believers, teachers, and martyrs of the gospel. The first alarm they received was from Mary Magdalene, who, early in the morning, on the third day from the burial of our Saviour, came running to inform Peter and John, that the stone was rolled from the mouth of the sepulchre, and that the body of the Lord was removed. These two apostles hastened to the sepulchre, and having entered it, found the fact that had been announced to them actually verified. Thus were their minds prepared for the extraordinary events that afterwards occurred. The life of Jesus, they knew,

had been a life of miracles; and his death had been attended with prodigies and wonders; and yet none of them, John excepted, believed that he was risen from the dead; for as yet (as that apostle assures us) *they knew not the scriptures, that he must rise again from the dead*; that is, they did not understand from the prophets, that the Messiah was to rise again from the dead; being, on the contrary, persuaded, that these very prophets had foretold the Messiah should *not die, but abide for ever*. The next report they received was from Joanna, and her companions, who acquainted them that angels had appeared to them, and had told them that Jesus was risen, reminding them, at the same time, that Christ himself had, not only from the spirit of prophecy with which it was known that he was endowed, but from the prophets also, predicted his own sufferings and death, and rising again from the dead on the third day. But then they did not understand what was meant by his "rising from the dead." In order to explain to them the meaning of the resurrection, they were probably acquainted, in the next place, by Mary Magdalene, that she had seen, not angels only, but Christ himself. Nevertheless some doubts and difficulties still remained. He had been seen only by Mary Magdalene. To relieve them in this state of hesitation and perplexity, nothing could be better calculated than the account given by the other Mary and Salome, who had also been at the sepulchre, and had there seen an angel, who not only assured them that "Christ was risen," but had ordered them to tell his disciples, "that they should meet him in Galilee," agreeably to what he himself had said to them in his lifetime. The only scruple that now remained in the minds of the apostles, arose from their not having seen him themselves; and till they did, they seemed resolved to suspend their belief of his being risen from the dead, and treated all those visions of the women as so many idle tales. They were left for some time to ruminate over the wonderful events that had rapidly occurred, to examine the scriptures, and to recollect the predictions and discourses of their Master, to which they were referred both by the angels and himself. In order to assist them in their inquiries, and lead them to the true sense of the scriptures, the only rational means of conquering their prejudice, Christ himself appeared to two of his disciples, on their way to Emmaus, whom he found discoursing and reasoning as they went upon those very topics. The design of Christ in his conversation with these disciples, and particularly in his exposition of the prophets, was to shew, that, by the proper exercise of their understandings, they might, from those very scriptures, whose authority they allowed, have been convinced that the Messiah "ought to have suffered," as they had seen him suffer, "and to rise from the dead on the third day." That is, Christ chose rather to convince them by *reason*, than by *sense*; or, at least, to prepare their minds, that their assent afterwards to the testimony of their senses, should be with the concurrence of their reason. Having duly prepared them for receiving the testimony of their senses, he discovered himself to them by an act of devotion, "in breaking of bread;" a form of devotion which he had instituted in remembrance of his death. Accordingly they were convinced, and "returned that same hour to Jerusalem," where they found the apostles assembled together, and debating apparently upon the several reports they had heard that day, and particularly upon what Peter had told them, to whom, some time on that day, Christ had appeared. The apostles having now had every kind of evidence laid before them that was requisite to convince them of the reality of the resurrection of Christ, and being also enabled by the gift of that Spirit, which inspired the prophets, to understand the true meaning of those sacred oracles

## RESURRECTION.

to which their Master constantly referred them for the marks and characters of the Messiah, which *he* affirmed to be found in himself; they were left again to themselves, that they might consider and examine at leisure the several proofs of the resurrection, which they had heard and seen, and particularly those arising from the accomplishment of the predictions contained in the holy scriptures. Accordingly he forbore visiting them for eight days, after which he condescended to submit himself to a farther examination, in order to remove the unreasonable scruples of St. Thomas, one of the apostles. After this there seems to have been no scruple left in the minds of any of the apostles, to whom, however, Christ was still pleased to continue his visits; "being seen of them," as St. Luke testifies (Acts, i. 3.) "forty days after his passion, and speaking of the things pertaining to the kingdom of God."

It is observable, that all the appearances of Christ already mentioned, seem to have been intended only for the conviction of his apostles; and those that follow, which were probably much more numerous than the evangelical history records, rather for their confirmation and instruction in the faith and doctrines of the gospel. The sacred writers have been very particular in their accounts of the former, whilst they have mentioned but very few of the latter; and the reason of their different proceeding is very obvious. The apostles are to be considered both as *witnesses* of the miracles, and the sufferings, the death, and the resurrection of Jesus Christ, and as *teachers* and *preachers* of his doctrine. In the character of *witnesses*, a circumstantial account of the means and opportunities they had of knowing certainly the several facts attested by them, must necessarily give great force and credit to their evidence: whereas in that of *preachers*, it is sufficient if their auditors were satisfied, in general, that the doctrines taught by them were derived from the instructions, and authorised by the commission given them by their Master, "to teach all nations;" and of this, the various gifts of the Holy Spirit, poured out, not upon the apostles only, but by them upon *all* believers, were full and unquestionable proofs.

From a review of the method and order in which the several proofs of the resurrection were laid before the apostles, it is manifest that Christ required of them a reasonable and well-grounded faith, and that he also pursued the most proper and effectual means for the attainment of that end. With this view, instead of bearing down their reason, and dazzling their understanding by a full manifestation of himself at once, we see him letting in the light upon them by little and little, and preparing their minds by the gradual dawning of truth, that they might be able to bear the full luster of the Sun of righteousness rising from the grave; to consider and examine, and know that it was he himself, and to assure the world it was impossible they could be deceived. By referring them to the scriptures, and submitting himself to the scrutiny and judgment of their senses, he not only waved all authority, but required them in a strong and particular manner to exercise their reason in examining the evidence brought before them; for which purpose he also improved their faculties by the infusion of his holy spirit. Never, says Mr. West, was evidence more fairly offered to consideration: never was inquiry put into a more rational method, as indeed there never were any facts that could better abide the test.

These facts, of which the *matter* of the evidence of the resurrection consisted, may be comprised under three heads, *viz.* the appearances of the angels, the appearances of Christ to the women, and the appearances of Christ to the disciples and apostles. Our limits will only allow us briefly to recite

them. Those of the *first* class, at the sepulchre on the morning of the resurrection, are such as were observed by the Roman soldiers, who kept the sepulchre, by the other Mary and Salome, by Mary Magdalene and by Joanna, and her companions. Mr. West has satisfactorily proved, by a train of reasoning which we have not room to pursue, that these appearances of the angels were neither the effects of illusion, the phantoms of a disordered visionary mind, nor the operations of artifice and imposture. The *second* class comprehends the appearances of Christ, which were two; the first to Mary Magdalene; the second, to the other Mary and Salome. Some persons have very absurdly inferred from our Lord's prohibition to Mary, expressed in these words, "Touch me not, for I am not yet ascended to my Father," that our Saviour was not clothed with a real or material body: whereas the evident meaning of the words is "detrain me not, for I am not yet ascended to my Father," and therefore they imply, that she should have another opportunity, before his departure from the world, of expressing her regard and maintaining intercourse with him. The *third* class of appearances includes those of Christ to his disciples, for the 40 days after his passion, which undoubtedly were numerous, though only few are recorded. An objection has been founded on one of these appearances, in recording which St. John says, "that Jesus came (the doors being shut) and stood in the midst," against the reality of the body of Christ; but it is needless to reply to so groundless a suggestion, as that the body of Christ passed through the solid door; when it is possible that he might enter, unperceived by them, through an open door.

The third time of our Saviour's appearance to any number of his disciples together after his resurrection was at the sea of Tiberias, called also the sea of Galilee (John, xxi. 14.); and subsequent to this was his appearance on a mountain in Galilee, mentioned by St. Matthew. One reason that has been assigned for his shewing himself in Galilee, after his resurrection, seems to have been, that, where he was personally known to so many people, having resided there above 30 years, he might have the greater number of competent witnesses to his resurrection. It is probable that the greatest number of his appearances for the 40 days after his passion were in Galilee, where he would have a favourable opportunity of discoursing to his disciples of "things pertaining to the kingdom of God," (Acts, i. 3.); and of preparing his apostles especially for testifying to the reality of his resurrection, and for executing the commission with which they were entrusted. Here they would be more secure, as well as more retired, than at Jerusalem.

It might be further urged that the resurrection of Christ was a necessary fulfilment of ancient prophecies pertaining to the Messiah, and also of our Lord's own predictions: and that it was a no less necessary appendage to his office as a teacher and saviour than his death. Without the resurrection, the great scheme of divine mercy for the benefit of mankind would have been incomplete; by that, it was perfected, and the triumph over death added to that over sin; the Messiah thus accomplishing all that the scriptures foretold of his glory and power. This event authenticates and confirms the promise of future existence, and is indeed the pledge and earnest of immortality.

But it has been objected, that all the proofs of our Lord's resurrection which have been above adduced were not exhibited to all the Jews. (Acts, x. 41.) That Christ made choice of a select number of disciples, and particularly of twelve, (who were called apostles,) to be witnesses of the great actions of his life, and especially of his resurrection, and preachers of his gospel to all the world, is a well-known and indisputable

## RESURRECTION.

able fact. He not only, on many occasions, both *before* and *after* his crucifixion, discoursed to them in particular of things "pertaining to the kingdom of God," and poured upon them all the various gifts of the Holy Spirit, but gave them every kind of evidence of his "being risen" from the dead, which the most scrupulous and sceptical could imagine or require; "shewing himself alive to them by many infallible proofs," such as eating and drinking with them, "for 40 days after his passion." And, indeed, it is highly expedient that those, upon whose testimony and credit the truth of any fact is to be established, should have the fullest and most unexceptionable evidence of it, that can be had; because their having had all possible means of information must necessarily add great weight and authority to their depositions. That their perfect knowledge of the things which they were to testify was necessary for those who were ordained to be apostles, is further evident from the words of St. Peter, Acts, i. 15—26. It was the peculiar and distinguishing character of the apostles to be witnesses of the resurrection, and it was their office to testify to the reality of this fact: but all the infallible proofs of our Lord's resurrection were not vouchsafed by him to his disciples, merely from a particular favour and regard to *them*, that *they* might believe and be saved; but with a further view, that *others* also, by their testimony, founded on the most complete and exact information, might likewise believe and be saved. If Christ had intended nothing more than to induce his disciples to *believe* his resurrection, he might have left them to the *testimony* of the Roman soldiers; to that of the *women*; to the *writings* of *Moses* and the *prophets*; to his own *predictions*; to the *state* of the sepulchre, and that wonderful circumstance of his body's being *nowhere* to be found; and they would have been without excuse, if they had still continued unbelieving. But though the apostles had, upon *this* evidence, believed their matter to be risen from the dead; yet, without those other *infallible* proofs mentioned by St. Luke, they would certainly have not been so *well* qualified for being witnesses of the resurrection to all the world: the heathens would not have admitted the *testimony* of Moses and the prophets, of whose writings they knew nothing, and of whose divine authority they had no proof. And as to the depositions of the *women*; besides their being strangers to *their* characters, they might, from Christ's appearing to *them*, with some colour have demanded, why he did not appear likewise to those whom he commissioned to *preach* his gospel, and to be *witnesses* of his resurrection. But when, on the contrary, the apostles could tell them, that they *themselves* had *seen* Christ, had *handled* him, *eat* and *drank* with him, and *conversed* with him for *forty* days *after* that he *was* risen from the dead, they could not but allow them to have had the *fullest* evidence of the resurrection, supposing what they told them to be *true*; and of this the purity of their doctrines, the holiness of their lives, their courage and constancy in defying and undergoing all kinds of hardships, dangers, pain, and death, in advancing a cause, which every worldly interest obliged them to desert, joined to the attestation of the Holy Spirit, "working with them, and confirming the word with signs following," were such assurances as no other man could give of his veracity. It has been said, however, that our Lord did not shew himself, after he was risen, to the Jews, to the chief priests and elders, to the Scribes and Pharisees, and mistakenly interpreting a passage in Matt. xii. 39, 40, Christ has been charged with a violation of his promise to this purpose. Of his rising again from the grave on the third day, the Jews had the testimony of the prophets, of the predictions of Christ himself, the evidence of the Roman soldiers, of his body's

being no where to be found, of the women and disciples, and apostles, to whom he had appeared; and who, before the Sanhedrim, bore witness to his resurrection, and having just before wrought a miracle upon a lame man (Acts, iv. 10.) declared, that they had done it in the name of "Jesus of Nazareth, whom," say they, "ye crucified, whom God raised from the dead." This surely was evidence sufficient to convince any reasonable and unprejudiced person, and, consequently, to acquit our Lord of his promise of giving that "evil generation" satisfactory proofs of his being risen from the dead. To the evidence vouchsafed by Christ, neither out of favour to those "who had forsaken all and followed him;" nor to those whom he had chosen to be "witnesses of him to all the world," they certainly could have no just pretensions; who, instead of being his disciples, had rejected his doctrine, and put him to death as an impostor and blasphemer; and instead of shewing any disposition to embrace and propagate his gospel, opposed it with all their power, and, by threats and punishments, forbade his apostles to preach any more in his name. It deserves consideration in this place, that the apostles were not chosen merely to be witnesses of the fact of our Lord's resurrection, but they were appointed to their office, and commissioned to publish it to the world, because, having often seen Christ after his resurrection, they were duly qualified for the service assigned them, and were able to testify the truth of it from their own knowledge. Although our Saviour did not think proper to appear to the people at large; that is, to the multitude of the Jews, who were the declared enemies of his person and religion, and particularly to the chief priests and magistrates, who had been the instruments of his crucifixion; he *shewed himself openly*, without reserve and disguise, to those who had been accustomed to associate with him; and to no fewer than to five hundred such persons at one time; and of the number of these were the twelve apostles, who were specially appointed to preach his doctrine, and to declare the fact of his resurrection, as a distinguishing evidence of its truth and importance. Their office commenced during the period of his public ministry; and one necessary qualification for the future exercise of it was their being able to attest his resurrection. Others might have borne a similar testimony. They were prepared and disposed to do it. But the apostles were particularly selected and ordained for this purpose.

It is a very natural inquiry, why the Jews in general, and the priests and rulers in particular, should not have had an opportunity of seeing Christ after his resurrection, and conversing with him, and ascertaining the reality of the fact? As this was the evidence of his divine mission and character, to which he had often appealed; should not those who perilled in their incredulity, notwithstanding the proofs of supernatural powers, which he had exhibited in the course of his life and ministry, have enjoyed the benefit of it? And if it had been sufficient to overcome their obstinate prejudices, would not their testimony have contributed, more effectually than any other concurring circumstance, to the conviction of mankind in general, and to the credit and influence of Christianity? This kind of reasoning, we allow, seems, on a slight and superficial consideration of it, to be very plausible; and it has been strongly urged and very pertinaciously maintained by sceptics and infidels.

Let us examine the principles upon which it is founded; and we shall perceive that it is more plausible than just, and that it will not warrant the conclusion that has been drawn from it. It supposes, that the Jewish priests and magistrates had a right to expect personal evidence of our Saviour's resurrection; that some useful and important end would

## RESURRECTION.

would have been answered by its being afforded them; and that no injury to the character and religion of Christ could have resulted from their being thus indulged and gratified. If neither of these suppositions can be reasonably admitted; if, upon farther investigation, they should appear to be fallacious and unfounded; it cannot be alleged against the evidence of our Saviour's resurrection, that it was defective and partial, because it was not communicated to the Jewish priests and rulers.

The plea of right cannot be urged in their favour by any, who duly consider, what their disposition and conduct had been during our Saviour's life and ministry. Men who had discovered no inclination to examine the nature of his doctrine and the design of his mission; who had slighted and resisted the means of information and conviction, which his preaching and miracles had afforded them; and who had pursued him with malignity and violence to the cross and grave;—such men could surely have no just claims on his farther attention: they could have no reason to expect, that he would condescend to use any new efforts for removing their prejudices, when every past endeavour had not only proved fruitless, but had served to exasperate their resentment, and to provoke a persecution which terminated in his death. Their opposition to him had been such both in its nature and degree, as to render them altogether unworthy of any forbearance and indulgence. Much less discernment than he possessed would have been sufficient for perceiving, that no evidence was likely to avail with persons of their temper and character. They had justly forfeited every token of his regard. They had merited the most signal punishment. It would have been not only a vain, but an impious and daring presumption in them to expect any other evidence of his restoration to life besides that, which they might derive from the testimony of persons less guilty and more deserving than themselves. Besides, our Saviour's particular commission to the Jews expired with his death; and he had previously informed them that they should not see him till they were better disposed to receive him. Every personal claim must, in this case, be set aside.

The plea of right being dismissed as unfounded, the next question that occurs is, whether any important and valuable purpose to themselves or others, would have been answered by our Saviour's appearance to them, after his resurrection? Have we any reason to imagine, that they would have been convinced of the truth of his mission and doctrine by such an appearance? The same prejudices and interests that prevented the effect of the miracles which he had performed, and of which they had been witnesses, would have resisted the conviction, which his resurrection tended to produce. The same antipathy to the doctrine he taught and the religion he meant to establish, would have prevailed against the evidence of this fact; and it is probable, that they would have only aggravated their guilt and condemnation by obstinately persisting in their unbelief.

But though they were convinced of the reality of our Saviour's resurrection, would they avow their conviction? Would they publicly testify the truth of that fact? By an undisguised and open declaration of it, would they lead others to believe and acknowledge it? This, indeed, would have been a very signal triumph of truth over prejudice and malice. But it would have been a triumph over their own prejudice and malice, of so extraordinary a kind, that it was very unlikely to happen. Pride and interest would have been very reluctant in acknowledging that they had persecuted and murdered a divine Messenger; in renouncing the worldly rank and

influence which they possessed; and in submitting to be taught and governed by the authority of Jesus of Nazareth, whom they had despised, calumniated, and crucified. If they were constrained to assent to the truth of our Saviour's resurrection, it was not very probable that they would confess to the world, that he, whom they had persecuted during his life, and doomed to a premature and ignominious death, was the promised Messiah and Saviour. It was not very probable, that in so doing they would publish their own disgrace, and that they would proclaim to the world, that they were persecutors and murderers. It would have required a degree of virtuous fortitude, of which we discover no traces in the Jewish Sanhedrim, to bear public testimony to the resurrection of a person whom they had so lately condemned and crucified as a malefactor. Without such a testimony, of what avail would have been the conviction of their own minds to the general credit of the Christian cause? Afraid or ashamed of avowing it, and thus of forfeiting the reputation and influence annexed to their character and office, and of incurring popular censure and reproach; no benefit could have accrued from it either to their contemporaries or to future generations. They were, therefore, very unfit to be witnesses of a fact, which it was their interest to conceal, and which they were not likely to acknowledge, if they had believed it to be true.

Besides, their testimony, if truth had extorted it from them, and if they had possessed honesty and resolution sufficient to avow it, would have been liable to suspicion. It was the testimony of men whose minds must have been oppressed and terrified by a consciousness of their guilt; and it might have been said, that they were haunted by ghosts and spectres, and that their imagination converted a phantom into the real person of him whom they had exposed to public derision, and sentenced to an ignominious death. Their testimony would have gained little credit with men of their own rank and station, and of principles and characters similar to their own. It would have died with themselves; and produced no effect beyond the circle of their own acquaintance and the age in which they lived.

It ought to be considered farther, that the character and religion of Christ might have been very materially injured by his appearance to the Jewish priests and rulers, after his resurrection. They had no right to expect this kind of evidence. No good purpose could be answered by it. We now observe, that it might have been very detrimental in its effects. If they had remained unconvinced, which might most probably have been the case, the fact would have been questioned. The multitude would have become obstinate and irreclaimable in their incredulity; and they would have pleaded the authority of their superiors in station and office, as an apology for neglecting inquiry and rejecting the means of conviction. If they had been convinced, without honesty and resolution to declare the truth, the fact would still have been considered as doubtful, or at least of no great importance. But if with their conviction they connected the public avowal of its truth, our Saviour would have incurred the charge of an impostor, and his religion of fraud. Loud would have been the clamour of a combination between him and the rulers of the state. Suspicion would have attached itself to the evidence of men, who had the care of his sepulchre, who appointed the guard, and sealed the stone that secured it, and who could easily have propagated a report, which would have gained credit with the servile multitude. Christianity would have been represented, by persons who are prone to ascribe all religion to state policy, as a contrivance of the priests and magistrates

## RESURRECTION.

trates of Judea, to answer some purpose of worldly emolument or ambition. Its progress and prevalence would have been attributed to the secular influence of its advocates; and it would have been deprived of that most distinguishing and satisfactory evidence which it now possesses, that it derived its origin from God, and owed its success to the signal interposition of divine power.

Allowing that the apostles and first disciples had sufficient evidence of our Lord's resurrection, we are next to inquire, in the discussion of this interesting subject, how the fact may be ascertained to the satisfaction of those who live in ages and nations far remote from those in which it occurred. Such persons must recur for conviction, first and principally to the testimony of the original witnesses, chosen to announce the fact to the world, transmitted from one country and one age to another in writings, either penned by themselves, or authorized by their inspection and approbation. These writings are contained in the *Gospels*, the *Acts*, the *Epistles*, and the *Revelation*; and for proofs of their authenticity and credibility, we refer to these titles, and also to BIBLE, CANON, and TESTAMENT; and for an account of their authors, to MATTHEW, MARK, LUKE, JOHN, PAUL, PETER, &c. How far we may safely, and without danger of mistake, rely on the testimony of the witnesses of our Saviour's resurrection, thus transmitted to us, will appear, if we consider, that they were men, not only capable of knowing the truth, and duly informed concerning it, but, on account of their general character, unlikely to report and propagate a falsehood. They had been raised from private and obscure stations to the office they sustained. They were destitute of those natural talents and external advantages which suggest and favour a plan of imposture and deceit. Artless and undesigned, and unconnected with persons of extended views and worldly influence, they were unfit instruments for concerting and executing a deliberate and complicated scheme of delusion. The principles they had embraced, and the profession they had assumed, since their conversion to Christianity, were altogether incompatible with a combination to promote the prevalence of a known falsehood. Integrity and a regard to truth, under the awe of the God of truth and justice, and in the prospect of righteous judgment and retribution, were the avowed principles of their conduct; and they must have been impostors, chargeable with the most atrocious guilt and the most consummate folly, if they had proposed, by the wickedness of deceit, to promote the cause of truth and virtue. But the falsehood of asserting, that Christ was risen, was such as would never have engaged their concurrence and support. It was an event of which they had no expectation. Their prejudices and false hopes had led them to surrender their cause, as altogether defeated, when their Master submitted to death. They had either forgotten or misunderstood his predictions; and when some of them first received the report of his resurrection, they were departing from Jerusalem with dejected and despairing spirits; and they needed very peculiar evidence of the fact, before they were disposed to admit the reality of it. If Christ had not actually risen from the dead, these men would have returned to their former attachments and occupations. All their prepossessions in favour of the perpetuity of the law of Moses would have revived. Disappointed in their erroneous expectations, they would have been the less inclined to propagate an imposture.

More especially when we consider, that all their interests, as well as their prejudices, militated against their public declaration of a fact, which had never existed. Can we suppose, that they would have incurred the resentment of

the whole body of the Jews; and that they would have hazarded their lives in the support of a cause, the founder of which had deceived and betrayed them? On the contrary, we discern in the temper and conduct of the witnesses of our Lord's resurrection undeniable evidence of their conviction of its truth, and of their sincerity in avowing and publishing it. Nothing less than the evidence of truth can account for the change which they manifested both in their sentiments and conduct. Men, who a little while before were timid and despairing, become bold and fearless; declare the fact on the scene, where they report it to have happened, and in the presence of those, who, after having succeeded in procuring the crucifixion of Christ, employed all the means in their power for preventing any delusion with regard to his resurrection; and who expose themselves to persecution and death in asserting and proclaiming it. With new views, with respect to the nature and extent of the Christian dispensation; with a knowledge and zeal, with a steadiness and constancy, which indicate a consciousness of truth and an extraordinary illumination; they publish the fact, and propagate the doctrines and duties which it was designed to establish and enforce.

Besides, "the apostles wrought miracles in confirmation of the truth of their testimony." The God of truth concurred with them, and attested their credibility; and thus obviated every doubt and difficulty, which prejudice and malignity might have suggested. Every miracle they performed was a new attestation to the fact which they reported, and the extraordinary powers they possessed, and which they derived from the Sovereign of nature, qualified them for being proper witnesses of it to the world. He, who appointed them to this office, aided them in the execution of it. Their success, insufficient as they were of themselves to combat the prejudices and powers of the world, afforded an increasing and permanent evidence of the fact, on which their commission was founded. To us their testimony has descended with every sanction and with every circumstance of credibility, that can justify our assent, and our attachment to the doctrine they taught, and to the practice of the duties they inculcated.

In the prevalence and duration of Christianity, and in the prospect of its continued subsistence and increasing spread and triumph, we discern traces of its divine original: we see existing proof of the resurrection of its founder; and we perceive reasons and motives for holding fast the profession of our faith in it without wavering. Our religion is founded on evidence, that cannot be reasonably questioned: the objections to which it is liable, furnish, on due examination, arguments in its favour. It needs only an impartial scrutiny and trial, in order to approve itself *the wisdom and the power of God*.

From the existence of the Christian religion, which we may consider as a distinct argument in proof of our Saviour's resurrection, may be deduced the same kind of evidence of this fact, as is exhibited to us of the deluge by the many petrifications of shells and bones of fishes, and other animals of distant regions, &c. found often in the bottoms of the deepest mines, and the bowels of the highest mountains; for, as it is impossible to account for those various petrifications being lodged in so many parts of the earth, some many leagues distant from the sea, others very much above the level of it, without admitting such a subversion and confusion of this globe, as could not have been occasioned by a less violent cause than the "breaking up of the fountains of the great deep, and the waters flowing above the tops of the highest hills;" so will it be extremely difficult to account for the propagation and present existence of Christianity in so many regions

regions of the world, without supposing that "Christ rose from the dead," ascended into heaven, and enabled his disciples, by the miraculous gifts of his holy spirit, to surmount such obstacles, as no mere human abilities could possibly overcome. See *CHRISTIAN Religion*. "Observations on the History and Evidences of the Resurrection of Jesus Christ," by Gilbert West, esq. "Observations on the Conversion of St. Paul," by the right hon. George lord Lyttelton. "The Trial of the Witnesses of the Resurrection of Jesus." Rees's Sermons, vol. i. Sermon 4.

The resurrection of Christ is a most important fact, not only as it certifies his divine mission, the character he assumed, and the truth of the doctrine he taught, but as it assures us of the reality of a future state of righteous retribution. This event exhibits a triumph over death, which proves not merely the possibility, but the certainty, of a general resurrection of mankind. It is the pledge and earnest of that restoration to life, which Jesus Christ, as a divine teacher, both predicted and promised. Many curious questions have been proposed on the mode of the future existence of mankind; as well as on the place of abode of the good and wicked (see *HEAVEN* and *HELL*); and also on the time when this interesting event shall happen. (See *SLEEP of the Soul*.) With regard to the mode of our future being, it is generally allowed, both by those who believe and those who deny the essential distinction between matter and spirit, that we shall exist hereafter in a corporeal form; but the difference between our present bodies and those in which we shall exist after the general resurrection is a subject, which, however it may have engaged the attention and employed the pens of metaphysicians and polemical theologians, is more curious than useful; and provided that we shall exist hereafter, we need not be anxious about the decision of this question. It is important merely as it relates to the doctrine of a future existence in general, the truth of which, whatever may be the conjectures of the learned, it does not invalidate.

Many Christians believe the resurrection of the same identical body, the very same flesh and bones, at the day of judgment. The two principal philosophical objections against it are these:

1. That the same piece of matter, or substance, may happen to be a part of two or more bodies. Thus a fish feeding on a man, and another man afterwards feeding on the fish, part of the body of the first man becomes first incorporated with the fish, and afterwards in the fish, with the last man. Again, instances have been known of one man's feeding immediately on another; and, among the cannibals of the West Indies, the practice has been frequent.

Now, where the substance of one is thus converted into the substance of another, each cannot rise with his whole body; and to which shall the common part be allotted?

To this objection some answer, that, as all matter is not fit or disposed to be assimilated to the body, and incorporated with it, human flesh may very probably be of this kind; and, therefore, what is thus eaten, may be again excreted, and carried off. But Mr. Leibnitz's answer seems the more solid. All that is essential to the body, he urges, is the original stamen which existed in the semen of the father; nay, and on the footing of the modern theory of generation, which existed in the semen of the first man. This we may conceive as the most minute speck or point imaginable; and therefore, not to be separated, or torn asunder, and any part of it united with the stamen of any other man. All this bulk we see in the body, is only an accretion to this original stamen; an addition of foreign matter, of new

juices, to the primary, solid stamen: there is, therefore, no reciprocation of the proper matter of the human body.

The second objection is this: the human body, we know, by the late discoveries in the animal economy, is continually changing; a man has not entirely the same body to-day as he had yesterday; and it is even computed, that in less than seven years' time, his whole body undergoes a change, and not a particle of the same body remains. Which of those many bodies, then, which the same person has in the course of his life, is it that shall rise? or does all the matter that has ever belonged to him rise again? or does only some particular system thereof? The body, *e. gr.* he had at twenty, at thirty, or at sixty years old? If only this or that body arise, how shall it be rewarded or punished for what was done in the other? with what justice does one person suffer, &c. for another?

To this it may be answered on Mr. Locke's principles, that personal identity, or the sameness of a rational being, consists in self-consciousness; in the power of considering itself the same thing in different times and places. By this every one is to himself what he calls *self*; without considering whether that self be continued in the same or divers substances. So far reaches the identity of that person. It is the same self now it was then; and it was by the same self which now reflects on an action, that action was performed.

Now, it is this personal identity that is the object of rewards and punishments, which we have observed may exist in different successions of matter; so that to render the rewards and punishments just and permanent, nothing needs but that we rise again with such a body as that we retain the consciousness of our past actions.

**RESUSCITATION.** See **RESURRECTION**, and **RE-VIVIFICATION**.

**RESUSCITATION of Plants**, in *Chemistry*, the art of reproducing a plant from its ashes. See **PALINGENESIA**.

Many have pretended to this art, and have shewn resuscitated plants in vials; but all these seem only particular instances of artificial chemical vegetations, of which many others may be given. The external appearances of these resemble plants, and the ignorant may easily take them for such; but when closely considered, there is a great difference to be found. See **Artificial VEGETATION**.

**RETAIL**, in *Commerce*, &c. the buying of goods in the great, or by wholesale, and selling them out again in small parcels.—"Qui rem integram ementes, per minutiores eam partes distrahebant."

**RETAIN**, *To*, spoken of mares, signifies *to hold*, *i. e.* to conceive after covering.

**RETAINER**, in *Law*, a servant not menial or domestic, that is, not continually dwelling in the house of his lord and master, but only wearing his livery, and attending on special occasions.

This livery was anciently given by a great man, and frequently for the maintenance of quarrels; whence it was jully prohibited by several statutes; as under Richard II. on pain of imprisonment, and grievous forfeiture to the king.

It was further prohibited by other statutes of the succeeding kings, by which the delinquents were subject to make ransom at the king's pleasure; and knights and esquires hereof duly attainted were to lose their said liveries, and forfeit their fees for ever.

Edward IV. added a special penalty of five pounds *per* month on every man that gave such livery, and as much on every person so retained, either by writing, word, or

oath. But most of these statutes are repealed by a statute 3 Car. I.

**RETAINER of Debts**, a remedy which the law gives to an executor or administrator for the debt, by allowing him to retain so much as will pay himself, before any other creditors whose debts are of equal degree. (See **DEBT**.) † The debts of co-executors shall be discharged in proportion. An executor of his own wrong shall not, in any case, be permitted to retain.

**RETAINING-FEE**, is the first fee given in any cause to a serjeant or counsellor at law, by which to make him sure, that he shall not be on the contrary side.

**RETALIATION, RETALIATIO**, the act of returning like for like. See **TALIONIS Lex**.

When a nation cannot obtain justice, either for a loss or an injury, it has a right to do itself justice. But before it declares war, there are various methods practised among nations for obtaining satisfaction. Among these is that called the law of retaliation, according to which we make another suffer exactly so much evil as he has done. Many have extolled this law, as being derived from the most strict justice; and can we be surprised at their having proposed it to princes, when they have even dared to give it for a rule to the Deity himself! The ancients called it the law of Rhadamanthus. Although a nation may punish another which has done it an injury, if it refuses to give just satisfaction; yet it has not a right to extend the penalty beyond what is required by its own safety. Retaliations, unjust between private persons, would be much more so between nations, because here the punishment would, with difficulty, fall on those who have done the injury. What right would you have to cut off the nose and ears of the ambassador of a barbarian, who had treated yours in the same manner? As to those reprisals in time of war, which partake of the nature of retaliation, they are justified on other principles. (See **REPRISALS**.) All that is true in this idea of retaliation is, that every thing be equal; the pain ought to bear some proportion to the evil required to be punished; the end and even the foundation of punishment requiring thus much.

**RETARDATION, RETARDATIO**, in *Physics*, the act of retarding; that is, of delaying the motion or progress of a body, or of diminishing its velocity.

The retardation of moving bodies arises from two great causes, the *resistance of the medium*, and the *force of gravity*.

The **RETARDATION from the Resistance** is frequently confounded with the resistance itself; because, with respect to the same moving body, they are in the same proportion. See **RESISTANCE**.

With respect to different bodies, however, the same resistance often generates different retardations. For if bodies of equal bulk, but different densities, be moved through the same fluid with equal velocity, the fluid will act equally on each; so that they will have equal resistances, but different retardations; and the retardations will be to each other as the velocities which might be generated by the same forces in the bodies proposed; that is, they are inversely as the quantities of matter in the bodies, or inversely as the densities.

Suppose, then, bodies of equal density, but of unequal bulk, to move equally fast through the same fluid, their resistance increases according to their superficies; that is, as the squares of their diameters. But the quantities of matter are increased in proportion to the cubes of the diameters: the resistances are the quantities of motion; the retardations are the celerities arising from them; and dividing the quantities of motion by the quantities of matter, you will have

the celerities; therefore the retardations are directly as the squares of the diameters, and inversely as the cubes of the diameters; that is, inversely as the diameters themselves.

If the bodies be equal, move equally swift, and are of the same density, but move through different fluids, their retardations are as the densities of those fluids.

And when bodies equally dense, and of equal bulk, are carried through the same fluid with different velocities, the retardations are as the squares of the velocities.

The **RETARDATION from Gravity** is peculiar to bodies projected upwards. A body thrown upwards is retarded after the same manner as a falling body is accelerated; only, in the one case, the force of gravity conspires with the motion acquired; and in the other, it acts contrary to it.

As the force of gravity is uniform, the retardation from that cause will be equal in equal times.

Hence, as it is the same force which generates motion in the falling, and diminishes it in the rising body, a body rises till it has lost all its motion; which it does in the same time in which a body falling would have acquired a velocity equal to that with which the body was thrown up.

Thus, also, a body thrown up will rise to the same height, from which falling, it would acquire the velocity with which it is thrown up; therefore the heights, which bodies thrown up with different velocities can rise to, are to each other as the squares of the velocities.

Hence, the retardations of motions may be compared together: for they are, first, as the squares of the velocities; secondly, as the densities of the fluids through which the bodies are moved; thirdly, inversely, as the diameters of those bodies; lastly, inversely, as the densities of the bodies themselves.

The numbers in the ratio compounded of those ratios, express the proportion of the retardations; multiplying the square of the velocity by the density of the fluid, and dividing the product by the product of the diameter of the body multiplied into its density; and working thus for several motions, the quotients of the divisions will have the same compound ratio to one another.

**RETARDATION of Motion, Laws of.** 1. If the motion of a body be uniformly retarded, that is, if its celerity be diminished equally in equal times, the space it passes over is one half of that it would pass over in the same time by an uniform motion.

2. The spaces described in equal times by an uniformly retarded motion, decrease according to the uneven numbers 9, 7, 5, 3, &c. See **ACCELERATION and MOTION**.

**RETCH, or RETCHES**, a name given by our farmers to an iron, or a pair of irons, which in the common plough serve to fasten the sheet to the beam. The retches are fastened to the sheet with nails, and to the beam with pins.

**RETCHANI**, in *Geography*, a town of Russia, in the government of Pilcov; 16 miles S. of Tropetz.

**RETCHING, or REACHING**, the effort or endeavour to vomit. See **NAUSEA**.

**RETCHNA**, in *Geography*, a circar or province of Hindoostan, situated between the rivers Rauvec and Chunaub; in which are the cities of Lahore, Ameenadab, Scalcot, and several other towns.

**RETE MALFIGHII**, in *Anatomy*, the network composing the cellular structure of the lungs.

**RETE Mirabile**, the plexus of vessels formed by the internal carotid arteries of animals, before they branch out to the brain. See **MAMMALIA**.

**RETE Mucosum**, the soft delicate layer of the integuments interposed between the cuticle and the true skin, in which

which the colour of the skin resides. This part is much thicker in the dark coloured than in the light races of man, and is black in the Negro. See INTEGUMENTS.

RETE *Tyflis*, a part of the excretory apparatus of the testicle. See the description of that gland in the article GENERATION.

RETE *Peny*, in *Ancient Records*, a customary due of one penny for every person to the parish priest.

RETEH, or ARRATAMA, in *Geography*, a district of Africa, in the country of Sugulmessa.

RETEINER, or RETAINER. See RETAINER.

RETENEGI, in the *Materia Medica*, a name used by Avicenna, and others, to express the common resin of the pine, or fir-tree, and sometimes common black pitch. The lexicographers have given us *storax* as the explanation of *retenegi*, but this is not warranted by any passage in the authors who use the word. It is certain, indeed, that the generality of authors have confounded the several sorts of resin and pitch-making trees together, and among them the pine, fir, cedar, and turpentine trees, are called by the same name, but the *storax-tree* is never included among the number. These were only confounded together, because of the similitude of the things they produced; but the *storax* was too different from all these, and too precious a gum not to be distinguished.

RETENTA, a word used by the medical writers to express things retained in the body, or which are not to be retained in a state of good health.

RETENTIO, RETINENTIA, in our law-books, is sometimes used to signify retinue.

RETENTION, RETENTIO, a faculty of the human mind, by which, in order to a farther progress in knowledge, it keeps or retains those simple ideas, which it before received by sensation or reflection.

This is done two ways. First, by keeping the idea which is brought into the mind for some time actually in view. This is called *contemplation*.

Secondly, by reviving those ideas in our minds, which have disappeared, and have been, as it were, laid out of sight. This is *memory*, which is, as it were, the repository of our ideas.

RETENTION is also used, in *Medicine*, &c. for the state of contraction in the solids, or vascular parts of the body, which makes them hold fast their proper contents.

In this sense, retention stands opposed to evacuation and excretion.

Retention and excretion make two of the non-naturals.

RETENTION is also frequently considered as a disorder, and defined the act of retaining the excrements, humours, &c. so as they cannot be voided out of the body. See INFANT.

It is the retention of peccant humours which causes such a disease.

RETENTION of Urine. See URINE, Retention of.

RETFORD, EAST, in *Geography*, a market and borough-town in North Clay division of the wapentake of Bassetlaw, county of Nottingham, England, is situated on the eastern bank of the river Idle, at the distance of 29 miles N.N.E. from Nottingham, and 145 miles N. by W. from London. Retford consists of two distinct parts, or districts, respectively named, from their position to the river, East and West Retford; the former of which is strictly the market-town, and the latter a separate parish, or suburb. Edward II. granted to the burgesses the right of choosing bailiffs for the government of the town; and Henry III. granted them a fair. By a charter from Henry VI., the bailiff was empowered to hold a court of record, and to

execute the office of escheator and clerk of the market. These immunities have since been confirmed, and others added by James I.; under whose charter, Retford is now governed by two bailiffs, a steward, twelve aldermen, two chamberlains, a town-clerk, and two serjeants at mace. The bailiffs and steward for the time being are justices of the peace, and of the quorum, within the borough. Retford sends two members to the national senate, and these are chosen by about 150 voters, composed of the bailiffs, aldermen, and freemen. Like most other small boroughs, it has occasionally been the scene of warm election contests. This place first exercised the right of representation in the early part of the reign of Edward II.; but it seems to have allowed this privilege to remain dormant from the ninth year of that king till the thirteenth year of queen Elizabeth, when the same was resumed, and has continued to be regularly exercised ever since. Formerly the county assizes were held here; but of late years all criminal trials have taken place at Nottingham, the county town.

Retford market-day is Saturday, weekly; and there are, besides, two annual fairs for horses and black cattle, held on the 23d of March and the 2d of October. At the commencement of the last century, a considerable malting business was carried on here; but Workop has occasioned its decline. At present, Retford is supported principally by its hat and sail-cloth manufactories. Major Cartwright some years ago established a worsted mill in the immediate vicinity; but the project, having proved unsuccessful, has been abandoned. An agricultural society was established here in 1799, under the auspices of the duke of Portland, viscount Newark, colonel Eyre, and others.

The public buildings in Retford are the town-hall, Slosswick hospital, a free-school endowed by Edward VI., an alms-house for twelve poor women, and the parish church. The last, called the corporation church, is a small, but neat, edifice, in the English style of architecture, though much modernized, particularly in the interior. The living is a vicarage, in the patronage of the duke of Devonshire.

On the western bank of the Idle, and connected with the borough by a handsome modern bridge, is the village of West Retford, which, however, is altogether distinct from East Retford, both as to civil and ecclesiastical jurisdiction. Here is an hospital, which was founded in 1666 by John Dorrel, M.D., for sixteen poor persons, who are allowed annually 10*l.* each, besides clothing, coals, &c. Much injury was done to this village by a heavy flood, which occurred in 1795; but it is nevertheless a very thriving place, as well as East Retford, and derives considerable advantage from its proximity to the Chesterfield canal. West Retford Hall, a seat of the Emerson family, is the most conspicuous ornamental object in the immediate neighbourhood. St. John's well, a mineral spring about a mile from Retford, has been long famed for its medicinal qualities. South-east of Retford is Grove-Hall, the seat of Anthony Hardolph Eyre, esq., M.P. for the county. The house is seated on an eminence in a finely wooded park. Thoroton's History of Nottinghamshire, folio, 1663. republished with large additions by John Throsby, 3 vols. 4to. vol. ii. Beauties of England and Wales, vol. xii. by Mr. Laird.

RETHEL, a town of France, and principal place of a district, in the department of the Ardennes; before the revolution, the capital of a small country, called the "Retelois." The place contains 4862, and the canton 12,473 inhabitants, on a territory comprehending 200 kilometres, in 23 communes. N. lat. 49° 30'. E. long. 4 27'.

RETHEN, a town of Westphalia, in the principality of

of Luneburg Zell, on the Aller; 32 miles W. of Zelle. N. lat.  $52^{\circ} 51'$ . E. long.  $9^{\circ} 18'$ .

RETHONDES, a town of France, in the department of the Oise; 5 miles N.E. of Compeigne.

RETHWISCHE, a town of the duchy of Holstein; 25 miles N.E. of Hamburg.

RETI, in *Hindoo Mythology*, a personification of Affection, and the fabled consort of Kama, the god of love. She is represented in pictures as a beautiful woman, on horseback sometimes, and in the act of throwing a lance. Allusions to this goddess, proverbial for beauty, occur very frequently in Hindoo writings. Under the article RADHA, that lovely goddess describes the glances of her eye as "keener than the arrows darted by the husband of Reti." She sometimes is styled "mother of Kama." That appellation occurs in the article RUNEKA of this work. Kama is often called "he who loveth the goddess Reti." On the occasion of the combustion of the god of love, as noticed under KAMA, the lamentations of the afflicted Reti are very touchingly related by the celebrated Kalidasa, author of Sakuntala. A whole book of his poem, entitled "Kumara-sambhava, or the Birth of Kumera," is occupied with her tender sorrows. This book Sir W. Jones's teacher, a learned Vaidya (see VAIDYA), was restrained from reading; considering the ceremonies of a marriage, that of Kama and Reti, at which Brahma himself officiated as father of the bridegroom, as too holy to be known by any but Brahmans. An instance somewhat similar, of a book being too holy to be read by individuals of an inferior class, is given under RAMAYANA. Farther particulars connected with the interesting goddess, the subject of this article, will be found under KAMA, KRISHNA, and PRADYAMNA.

RETIARII, in *Antiquity*, a kind of gladiators, thus denominated from a net which they made use of against their antagonists, who were called *secutores*, and sometimes *myrmillones*. See GLADIATOR.

The word is formed from the Latin, *rete, net*; or perhaps from *retejaculum*; for they call their net *jaculum*, and sometimes in one word *retejaculum*.

This net they carried under their buckler, and, when opportunity served, cast it over the head of their antagonist, and, in this condition, killed him with a trident, or three-grained spear, which they bore in the other hand.

Lipius and others observe, that they fought in tunics, and were furnished with sponges to wipe off the sweat, blood, &c. and to stop their wounds.

RETICENCY, RETICENTIA, a figure in *Rhetoric*, by which we make oblique mention of a thing, in pretending to pass it over unmentioned.

Thus: *to say nothing of the nobility of his ancestors: I forbear to speak of his courage, and pass over the severity of his morals.* See APOSIOPESIS and PRETERITION.

RETICULA, RETICULE, in *Astronomy*, a contrivance for the exact measuring of the quantity of eclipses, introduced several years ago by the Royal Academy of Paris. See ECLIPSE.

The reticule is a little frame, consisting of thirteen fine silken threads, equidistant from each other, and parallel; placed in the focus of object-glasses of telescopes; that is, in the place where the image of the luminary is painted in its full extent. Of consequence, therefore, the diameter of the sun and moon is by this seen divided into twelve equal parts or digits; so that, to find the quantity of the eclipse, there is nothing to do but to number the luminous and the dark parts.

As a square reticule is only proper for the diameter, not for the circumference of the luminary, it is sometimes

made circular, by drawing six concentric equidistant circles. This represents the phases of the eclipse perfectly.

But it is evident, that the reticule, whether square or circular, ought to be perfectly equal to the diameter or circumference of the sun or star, such as it appears in the focus of the glass, otherwise the division cannot be just. Now this is no easy matter to effect, because the apparent diameter of the sun and moon differ in each eclipse; nay, that of the moon differs from itself in the progress of the same eclipse.

Another imperfection in the reticule is, that its bigness is determined by that of the image in the focus; and of consequence it will only fit one certain magnitude.

But M. de la Hire has found a remedy for all these inconveniences, and contrived that the same reticule shall serve for all telescopes, and all magnitudes of the luminary in the same eclipse. The principle on which his invention stands is, that two object-glasses applied against each other, having a common focus, and there forming an image of a certain magnitude, this image will increase in proportion as the distance between the two glasses is increased as far as a certain limit.

If, then, a reticule be taken of such a magnitude, as just to comprehend the greatest diameter the sun or moon can ever have in the common focus of two object-glasses applied to each other, there needs nothing but to remove them from each other, as the star comes to have a less diameter, to have the image still exactly comprehended in the same reticule.

Another improvement is, that whereas the silken threads are subject to swerve from the parallelism, &c. by the different temperature of the air; a reticule may be made of a thin looking-glass, by drawing lines or circles on it with the fine point of a diamond; which shall be safe from any alteration of the air. See MICROMETER.

RETICULAR BODY, *corpus reticulare*, in *Anatomy*, a body of vessels lying immediately under the cuticle or scarf-skin. See INTEGUMENTS.

RETICULAR PLEXUS, *plexus reticularis*, sometimes denotes the choroides, which is thus called, because its fibres are interwoven like a net.

RETICULARIA, in *Botany*, a genus of *Fungi*, named by Bulliard, from the reticulated appearance of its structure when ripe. It is the LYCOGALA of Micheli, Perfoon, and others; see that article.

RETICULARIS MEMBRANA, in *Anatomy*, a name sometimes given to the cellular substance. Dr. Hunter speaks of the cellular substance, which contains no fat, under this name, giving the appellation of adipous cellular substance to the other.

RETICULUM, in *Comparative Anatomy*, one of the divisions of the stomach in ruminating animals, so called from the reticulated arrangement of the folds of its internal membrane. See MAMMALIA.

RETIERS, in *Geography*, a town of France, in the department of the Ille and Vilaine, and chief place of a canton, in the district of Vitre; six miles W.S.W. of La Guerche. The place contains 2384, and the canton 14,638 inhabitants, on a territory of  $237\frac{1}{2}$  kilometres, in 10 communes.

RETIMO, a town of the island of Candia, built on the ruins of the ancient Rithymna. The environs of this town afford prospects that are very picturesque:—gardens planted with orange-trees, among which rise some date-trees; fields covered with olive-trees and kitchen-garden plants; rising grounds, on which the vine, the fig-tree, the mulberry-tree, and the almond-tree grow together; and

farther

farther on, wooded mountains:—to the west, the citadel, the harbour, and the sea. In a word, every thing concurs to render Retimo the most agreeable town in the island. It would also have become, perhaps, the richest, and the most populous, if the harbour, small as it is, had been kept in order. At present it is only practicable for the barks of the country; ships remain in the road, but rarely anchor here; and thus Retimo, which, from its position, the abundance of oil which is collected in its vicinity, and the other productions of its territory, might be an important place of trade, has, as well as Candia, seen a part of its population pass to Canca. Its present population, says Olivier, consists of from 5 to 6000 inhabitants, half Greeks, half Turks: the Jews here are not so numerous as at Candia.

This town, weakly defended, was plundered and ravaged by the Turks, as far back as the year 1572, while Selim II. was causing the siege of Famagusta, in Cyprus, to be pushed on with vigour; but it was not till the reign of Ibrahim, in 1645, that the Venetians were driven from it for ever; 40 miles W. of Candia. N. lat.  $35^{\circ} 20'$ . E. long.  $24^{\circ} 21'$ .

The province of Retimo is one of the best cultivated and most productive of the island; it furnishes a great deal of oil, a little barley and wheat, and a tolerably large quantity of wine. The rising grounds and hills which skirt the shores of Armiro are almost all covered with vines. On the nearest mountains which lie to the south, is a forest of common and native oaks, maples, and carob-trees, into which the inhabitants of Retimo come to cut the wood, of which they stand in need. To the south of Retimo are the two provinces of Aion-Vassali and Amuri, the only ones that are comprised in this pachalic; they furnish wheat, barley, oil, and some fruits. The former, situated to the N.W. of the other, furnishes, besides, excellent cheese, which is confounded in trade with that of Sphachia. The Greeks are more numerous than the Turks in the provinces of Aion-Vassali and Amuri. Olivier and Sonnini.

RETINA, in *Anatomy*, a membrane of the eye, formed by the expansion of the optic nerve, and constituting the immediate organ of vision. See EYE.

RETINA, in *Optics*. The retina is usually supposed to be the great organ of vision, which is effected by means of the rays of light reflected from each point of the objects refracted in their passage through the aqueous, vitreous, and crystalline humours, and thus thrown on the retina, where they paint the image of the object; and where they make an impression, which is continued thence, by the fine capillaries of the optic nerves, to the sensory. See EYE and VISION.

Indeed, whether the retina, or the choroides, be the principal organ of vision, and that on which the images of objects are represented, has been much controverted between several members of the Royal Academy; particularly Messrs. Mariotte, Pecquet, Perrault, Mery, and de la Hire. Mariotte first referred vision to the choroides, and was seconded by Mery; the rest asserted the cause of the retina.

The retina was always judged to have all the characters of the principal organ. It is situated in the focus of the refraction of the humours of the eye; and of consequence receives the vertices of the cones of rays, proceeding from the several points of objects. It is very thin, and consequently very sensible. It has its origin from the optic nerve, and is itself wholly nervous; and it is the common opinion, that the nerves are the vehicle of all sensations. Lastly, it communicates with the substance of the brain, where all sensations terminate.

As to the choroides, its use was supposed to be to stop the rays, which the extreme tenuity of the retina should let pass; and to do the same office with respect to the retina, which the quicksilver does to a looking-glass; especially in those animals in which it is black.

But from an experiment of a cat plunged into water, M. Mery conceived a different opinion. (See PUPIL.) He observed the retina to disappear absolutely on that occasion, as well as all the other humours of the eye; while the choroides still appeared distinctly, and even with all the lively colours which it has in that animal. Hence, he concluded, that the retina was as transparent as the humours, but the choroides opaque; consequently the retina was not a proper instrument to terminate and stop the cones of rays, or to receive the images of objects; but that the light must pass through it, and could only be stopped on the choroides; which therefore would become the principal organ of vision. The black colour of the choroides in man is extremely favourable to this opinion; the principal organ should seem to require, that the action of the light should terminate on it as it arrives; which it is certain it here does in the black, that absorbs all the rays, and reflects none; and it should also seem necessary, that the action of the light should be stronger on the organ of sight than any where else: now it is certain that the light, being received and absorbed in a black body, must excite a greater vibration there than any where else; and hence it is that black bodies are kindled by a burning-glass much sooner than white ones.

The situation of the choroides behind the retina is another circumstance on its side; M. Mery having observed the same position of the principal organ behind a mediate organ in the other senses, which makes an happy analogy. Thus the cuticle extended over the skin is the mean organ of feeling; but the cutis underneath is the principal organ. The like is observed in the ear, nose, &c.

The retina, therefore, should seem a kind of mediate or secondary organ, serving to break the too strong impression of the light on the choroides, or to preserve it; which is the use ascribed to the cuticle. Add to all this, that the retina is insensible, as having its origin from the medullary substance of the brain, which is so too; and the choroides, on the contrary, is very sensible, as arising from the pia mater, which is certainly sensible in a great degree.

This last argument being doubted of, M. Mery was engaged to prove it; which he did before the Royal Academy, where he shewed that the optic nerve is not composed, like the other nerves, of fibres; that it is only a train of the medulla inclosed in a canal, out of which it is easily separable.

This structure of the optic nerve, hitherto unknown, shews that the retina can be no membrane; it is only a dilatation of the medulla, inclosed under two membranes; and a path or medulla seems no proper substance to be the seat of sensation. It can scarcely serve for any thing but to filtrate the spirits necessary for the action of vision. The vibration, by which the sensation itself is effected, must be made on a part more solid, more firm, and more susceptible of a brisk impression.

For other arguments in favour of the choroides being the seat of vision, see CHOROIDES.

RETINA, *Paralytic*, and *Diseased*. See GUTTA SERENA. RETINACULUM, the name of a surgical instrument used in castration, and in the operation for a hernia, to prevent the intestines from falling into the scrotum.

RETINARIA, in *Botany*, was so called by Gærtner, from *rete*, a net, or rather more immediately perhaps from the

the anatomical word *retina*, applied to the nervous network of the eye. This genus was founded, by the above author, on a fruit given him by professor Hermann, and said to belong to a climbing shrub of the Mauritius. So nearly do Gærtner's plate and description approach to the fruit of *Gouania domingensis*, that we have no doubt of their belonging to some species of the same genus; probably to one that we have described in our article *GOUANIA*, though, possessing none but the *domingensis* in fruit, we cannot exactly appropriate Gærtner's synonym. He seems not to have been acquainted with the fruit of a *Gouania*.

**RETINASPALTUM**, in *Mineralogy*, a name given to an inflammable kind of resinous substance, accompanying Bovey coal. It has a pale brown ochre-yellow colour, is very brittle, and breaks with a vitreous fracture. Its specific gravity is 1.135. When held in the hand for some time, it emits a slightly resinous smell, but when burned it has a fragrant odour; at last the smell is bituminous. On the first application of heat it melts and smokes, and then burns with a bright flame. When the melted mass is cooled, it is black and brittle, and breaks with a glassy fracture. It is not acted on by water, but is partly dissolved by alcohol, potash, and nitric acid; the dissolved portions having the properties of a resin; the undissolved of asphaltum. It was analysed by Mr. Hatchett, and is composed of

55 Resin,  
41 Asphaltum,  
3 Earths.

A similar substance occurs in the wood coal at Cologne, and was also recently discovered in making the excavation for the Tunnel at Highgate. It may be doubted, however, whether these substances are more entitled to be ranked among minerals than the other vegetable matters found in alluvial ground.

**RETINUE**, **RETINENTIA**, the attendants or followers of a prince, or person of quality, chiefly in a journey.

In *Law*, those persons are properly said to be of a nobleman's retinue, who belong to him in quality either of servants or retainers.

**RETIRADE**, in *Fortification*, a kind of retrenchment made in the body of a bastion, or other work, which is to be disputed inch by inch, after the first defences are dismantled. It usually consists of two faces, which make a re-entering angle. When a breach is made in a bastion, the enemy may also make a retirade, or a new fortification behind it.

**RETIRED FLANK**. See **FLANK**.

**RETIRED List**, a list on the marine establishment, on which superannuated officers are placed.

In the East India service, the company have resolved that a military officer, after 20 years' actual service in India, who comes to Europe upon leave, may be allowed to retire on the pay of his rank, provided he signifies his intention of so doing, within 20 months after his arrival. Officers on leave who are desirous of retiring, and who declare their intention to that effect, within 12 months from their arrival, will be permitted to retire on the pay of the rank to which they may be intitled at that period. An officer having completed 22 years' residence in India will be allowed to retire on the full pay of his rank, directly on his leaving India.

**RETMANDORF**, or **RADOVELZA**, in *Geography*, a town of the duchy of Carniola, on the Save; 52 miles W. of Cilley. N. lat. 46° 22'. E. long. 14° 5'.

**RETONVILLER**, a town of France, in the department of the Somme; four miles N.E. of Roye.

**RETORBIO**, a town of Italy, in the Pavese; 14 miles S. of Pavia.

**RETORNO** *Falso Brevium*, in *Law*. See **FALSO**.

**RETORNO Habendo**, &c. See **RETORNO habendo**, and **REPLEVIN**.

**RETORT**, **RETORTA**, in *Chemistry*, a kind of crooked matrass, or a round bellied vessel, made of earth, glass, or metal, with a slender crooked beak or neck, to which the recipient is to be fastened.

From this form this vessel has been probably called a *retort*. The most capacious part is called the belly; its upper part the arch or roof of the retort; and the bent part, which makes with the belly an angle of about sixty degrees, is the neck; and the passage from the belly to the neck should be free and wide, and gradually diminishing to the extremity of the neck or mouth of the retort. Retorts differ in form and materials; their bellies are generally round; some of them are oblong, and shaped like a cucurbit, and these are called *English* retorts. They are preferable for the distillation of matters which are subject to swell, and to pass into the receiver before they be decomposed.

A retort, which has a little hole pierced in its roof, is called a *tubulated* retort. This hole must be capable of being exactly closed with a stopper of proper materials. Retorts of this kind are employed in distillations, where some matter must be introduced into the retort after the receiver is joined to it, as in the distillation of smoking marine acid, and in the operations for procuring the several kinds of clyffus.

When the retort is of glass, it is usually covered with a lute of loam, &c. an inch thick, to enable it to bear the fire the better; and it is used for all operations which require a less heat than is sufficient for its fusion. Earthen retorts are necessary when great heat is requisite, as in the preparation of phosphorus.

The retort seems to draw spirits and oil from woods, gums, minerals, earths, and other matters which require a strong fire.

The retort is a kind of compendium or improvement on the cucurbit and bolt-head; answering all the purposes of both, without the assistance of a capital or head, which the other require.

The quantity of air arising from some substances is apt to burst glasses in distilling; Dr. Browne Langrish has, therefore, given us a new contrivance of applying receivers to retorts, by which such accidents may be prevented. To his first receiver he adapts a second, inserted into an opening at the top of the first, in order to give more room to the rarefied and new generated air. To an opening at the bottom of each of these receivers, he fixes a bottle, tied on close by means of a bladder, so that they may be removed at any time, and another instantly placed in their room; by which means very little of the steam will escape. He also ties on a bladder to an opening, or upper neck of the second recipient; and this bladder being much thinner and weaker than any of the glasses, will always give way first, and prevent their bursting. And even when there is the greatest danger of this accident, the smallest pin-hole made through the top of the bladder, as soon as the fumes begin to rise, will be sufficient to let out the air as fast as it is generated. See *Philos. Transact.* N° 475. sect. 3. where we have a figure of the whole apparatus. For a farther account of the retort, and the uses to which it is applied; see **DISTILLATION** and **LABORATORY**.

**RETORTION**, in *Political Economy*. When a sovereign is not satisfied with the manner in which his subjects are treated by the laws and customs of another nation, he is at liberty to declare, that he will treat the subjects of that nation in the same manner as his are treated. This is what

is called the "law of retortion;" in which there is nothing that is not conformable to just and found politics; for no one can complain of being treated as he treats others. This law of retortion may also take place with regard to certain regulations, of which we have no right to complain, and which we are even obliged to approve, though it is proper to guard against their effects, by imitating them. Such are the orders relating to the exportation of certain commodities or merchandize. It is also frequently not convenient to make use of retortion; in this respect we ought to follow the dictates of prudence.

RETOW, in *Geography*, a town of Samogitia; 12 miles W. of Medniki.

RETRACTATION, *RETRACTATIO*, the act of unfaying what a person had said or written.

Galileo made a public retractation of his doctrine of the world, *De Mundo*, after its being censured and condemned by the pope. See *COPERNICUS* and *GALILEO*.

Among St. Augustine's works is a book of "retractations;" where, however, the word is to be understood in a new sense; not as if he recanted or unsaid any thing he taught, but only treated of the same matter, or handled the same subject, a second time. This sense the word will very well bear; being a compound of *re*, *again*, and *tracto*, *I handle, treat of*.

RETRACTION, *RETRACTIO*, formed from *retrahere*, *to draw back*, in *Anatomy*, the contraction or shortening of a part. A retraction of the nerves takes away the use of the limbs.

RETRACTS, among *Horsemen*, pricks in a horse's feet, arising from the fault of the farrier in driving nails that are weak, or in driving them ill-pointed, or amiss.

These, unless timely prevented, fester, and prove very dangerous. When the farrier, in shoeing, perceives the horse to shrink at every blow on the nail, it is a sign of a retract, and the nail is to be pulled out again; which is done without any harm.

When the horse halts immediately after he is shod, it is concluded some of the nails press the veins, or touch him in the quick.

To find where the grievance lies, they knock the nails round with a hammer, till the horse's shrinking upon hitting a particular nail discovers the place.

Some farriers give this as a rule, that throwing water on the hoof, the place where he is hurt will be dry sooner than any of the rest. The places where the horses are most usually pricked, are, the heel in the fore-foot, and the toe in the hind-foot.

RETRAHENS, in *Anatomy*, a muscle of the external ear. See *EAR*.

RETRAXIT, in *Law*, is where the plaintiff comes into court in person, alone, or with the defendant; and declares he will proceed no farther in his action.

A retraxit is peremptory, and a perpetual bar, and may be pleaded as such to the plaintiff in the same action for ever. See *NONSUIT*.

RETREAT, in *Ornamental Gardening*, any sort of erection, place, or convenience, formed in gardens or pleasure grounds for the purpose of recreation and amusement. These are of very different kinds, according to the nature of the particular grounds or gardens, their circumstances, and situations; as covered, open, or in other forms, as the taste of the proprietor or designer may direct. They may be made either in the different quarters, centre parts, angles, or other places of these situations, or formed in the range of hot-houses, as is the case in some instances. The particular forms, designs, and means of construction of them, are so

various, but, for the most part, so well known, that it is unnecessary to give any description of them in this place. Those of the more ornamental kind should, however, in general, be contrived somewhat in conformity to the style of the ground, garden, place, and proprietor; being furnished from designs of great diversity and number, as well as of various degrees of elegance, from that of the simple bower of honeysuckle, hop, or vine, twined upon bent poles, to the Grecian porch or temple of the finest sort of masonry. Great caution is, however, required in the introduction of these sorts of ornamental erections into gardens of the culinary kind. And in them, as with every thing else which relates to them, use, Mr. Loudon supposes, should be the prevailing idea; and that, as *use* and *beauty* go hand in hand, the most vulgar objects may be dignified by the judicious introduction of elegance. A garden of the kitchen kind, though unmixed with productions purely ornamental, is still, it is thought, a pleasing scene, because full of *utility* and *animation*, and constantly varying from the practice of cultivation, as well as from the seasons. It is consequently very generally resorted to at most times of the year, but especially in the early spring months. Of course, in a climate so very variable as this, wherever the walks are frequently made use of at such a season, there should, it is said, be covered retreats or places for retiring to, which should correspond with the whole of which they are conspicuous parts or portions. In this way they may constantly be made to harmonize with the different objects around them.

RETREAT, in *War*, the retiring or moving back again of an army, or part of it.

We say, to sound a retreat, to secure a retreat, &c.

What they call a retreat in the armies, is really a flight; only a flight made by design, and with conduct.

The skill and ability of the general is known by his retreats more than his engagements. The retreat of the ten thousand Greeks under the command of Xenophon, has been admired in all antiquity.

The three most celebrated retreats of modern times have been general Moreau's retreat in 1796, that of Prague, and that of general Macdonald in Italy.

RETREAT, *Chequered*, *Rétraite en échiquier*, Fr. is so called from the several component parts of a line or battalion, which alternately retreat and face in the presence of an enemy, exhibiting the figures of the chequered squares upon a chess-board. In the "General Rules and Regulations," (part 4.) it is judiciously observed, that all manœuvres of a corps retiring, are infinitely more difficult to be performed with order, than those in advancing. They must be more or less accomplished by chequered movements; one body by its numbers or position, facing and protecting the retreat of another; and if the enemy presses hard, the whole must probably front in time and await him; as the ground narrows or favours, different parts of the corps must double; mouths of defiles and advantageous posts must be possessed; by degrees the different bodies must diminish their fronts, and throw themselves into column of march when it can be done with safety.

The chequered retreat by the alternate battalions or half battalions of a line going to the rear, while the others remain halted, cover them, and in their turn retire in the same manner, is the quickest mode of refusing a part of a corps to the enemy, and at the same time protecting its movement, as long as it continues to be made nearly parallel to the first position.

In the chequered retreat the following rules must be observed: The battalions of the division nearest to the enemy,

will form flanks as soon as there is nothing in their front to cover them; but the other divisions will not have any flanks except to the outward battalion of each. The battalions always pass by their proper intervals, and it is a rule in retiring, that the left of each shall always pass the right of the neighbouring one. Whatever advantages the ground offers, those advantages must be seized, without too critical an observance of intervals, or minute adherence to the determined distance of each retreat. The division next the enemy must pass in front, through the intervals of the division immediately behind, and any battalion, that finds it necessary, must incline for that purpose. The retiring division must step out, and take up no more time than what is absolutely required to avoid confusion. The division nearest the enemy fires by platoons standing; the flanks of its battalions only fire when the enemy attempts to push through the intervals. When that division retires, it fires on, skirmishes by men detached from its light company, if present, or from platoons formed of rear rank men of one or two of the companies, and placed behind the flanks of the battalions. But should any of its battalions be obliged to halt and to fire, a shorter step must then be taken by the line; and should the enemy threaten to enter at any of its intervals, besides the fire of its flanks, such platoons of the line behind it, as can with safety, must give it support.

RETREAT is a beat of the drum in the evening, at the firing of a piece called the evening-gun, at which the drum-major, with all the drums of the battalion, except such as are upon duty, beat round the regiment; the drums of the quarter-guards, of the general-guards, and all other small-guards, do likewise beat; the trumpets at the same time sounding at the head of their respective troops. This is to warn the soldiers to forbear firing, and the sentinels to challenge, till break of day, that the reveille is beat.

The retreat is likewise called *setting the watch*.

In fortified places, this is a signal for the inhabitants to come in before the gates are shut. See DRUM.

RETREAT, or *Relay*, in *Masonry*, denotes a little recess or diminution of the thickness of a wall, rampart, &c. in proportion as it is raised.

The retreat is properly the diminution of a wall, without side, or the contraction of its upper courses more than the foundation. Where the foundation is very large, they usually make two or three retreats. Parapets are always built with retreats.

RETRENCHMENT, in a general sense, literally signifies the cutting off or taking from a thing: in which sense it coincides with subtraction, diminution, &c.

The word is French, *retrenchment*, formed of *re*, and *trencher*, to cut.

RETRENCHMENT, in *Architecture*, *Carpentry*, &c. is used not only for what is cut off from a piece when too large, in order to a better proportioning it, or some other convenience, but also for the projections taken out of streets, public ways, &c. to render them more even, and in a line.

RETRENCHMENT, in *War*, denotes any kind of work cast up to strengthen or defend a post against the enemy.

Such are ditches with parapets, gabions, fascines, &c. for a covering, &c.

The enemy came with design to oblige them to raise the siege; but could not force the retrenchments.

Retrenchments are either *general* or *particular*.

*General* retrenchments are a kind of new defence made in a place besieged, to cover the defendants, when the enemy becomes master of a lodgement on the fortification, that they may be in a condition of disputing the ground inch by inch, and of putting a stop to the enemy's progress, in ex-

pectation of relief; as, if the besiegers attack a tenaille of the place, which they judge the weakest, either by its being ill flanked, or commanded by some neighbouring ground; then the besieged make a great retrenchment, inclosing all that part which they judge in most danger. These should be fortified with bastions and demi-bastions, surrounded by a good ditch countermined, and higher than the works of the place, that they may command the old works, and put the besiegers to infinite trouble in covering themselves.

*Particular* retrenchments, or retrenchments within a bastion, (*retranchemens dans un bastion*, Fr.) must reach from one flank to another, or from one casemate to another. It is only in full bastions that retrenchments can be thrown up to advantage. In empty bastions you can only have recourse to retirades, or temporary barricades above the ramparts. The assailants may easily carry them by means of hand grenades, for these retrenchments never flank each other. It is necessary to raise a parapet, about five or six feet thick, before every retrenchment. It must be five feet high, and the ditches as broad and as deep as they can be made. There must also be small mines run out in various directions, for the purpose of blowing up the assailants, should they attempt to force the retrenchments.

RETRENCHMENT is more particularly used for a simple retirade made on a horn-work or bastion, when it is intended to dispute the ground inch by inch. See RETIRADE.

It is usually a re-entering angle, whose faces flank each other; and is fortified with ditches, parapets, gabions, &c.

RETRIBUTION, *RETRIBUTIO*, a handsome present, gratuity, or acknowledgment, given in lieu of a formal salary or hire, to persons employed in affairs that do not so immediately fall under estimation, nor within the ordinary commerce in money.

Those who ministered at the altar anciently lived on retributions, which they received for the services they did the church. But these retributions were afterwards judged proper to be fixed to precise sums.

RETRIEVE, *RETROUVER*, to recover, get again, or repair a thing lost or damaged.

To retrieve, in *Falconry*, signifies to bring or find partridges again, which have been once sprung before.

RETROACTIVE, compounded of *retro*, backwards, and *ago*, I *am*, in *Law*, that which has an influence or effect on time past.

New laws and statutes, we say, have no retroactive effect; that is, they have no force or effect as to what is already passed; nor can be alleged as rules for any thing done before their promulgation. Their authority is wholly as to what is to come.

Indeed we have some instances of laws that have a retrospect to retroaction, *i. e.* are made with express design to extend to things already past. These we usually call laws *ex post facto*.

RETROCESSION, *RETROCESSIO*, the act of going backwards, more usually expressed by *retrogression*, or *retrogradation*.

RETROCESSION of the Equinox. See PRECESSION.

RETROCESSION of Curves, &c. See RETROGRADATION.

RETROGRADATION, or RETROGRESSION, the act or effect of a thing moving backwards.

RETROGRADATION, in *Astronomy*, is an apparent motion of the planets, in which they seem to go backwards in the ecliptic, and to move contrary to the order or succession of the signs.

When a planet moves in *consequentia*, *i. e.* towards the following signs, or according to the order of the signs, as from

Aries to Taurus, from Taurus to Gemini, &c. that is, from west to east, it is said to be direct.

When it appears for some days in the same point of the heavens, it is said to be *stationary*.

And when it goes in *antecedentia*, i. e. towards the antecedent signs, or contrary to the order of the signs, viz. from east to west; it is said to be *retrograde*.

The sun and moon always appear direct. Hersehel, Saturn, Jupiter, Mars, Venus, and Mercury, sometimes direct, sometimes stationary, sometimes retrograde.

The superior planets are retrograde about their opposition with the sun; the inferior ones about their conjunction. The intervals of time between two retrogradations of the several planets are unequal.

These changes of the courses and motions of the planets are not real, but only apparent: when viewed from the centre of the system, i. e. from the sun, they appear always uniform and regular. The inequalities arise from the motion and position of the earth from which they are viewed, and are thus accounted for:

Suppose PNO (*Plate XIX. Astronomy, fig. 12.*) a portion of the zodiac, ABCD the earth's orbit, and EMGHZ the orbit of a superior planet, e. gr. Saturn; and suppose the earth in A, and Saturn in E, in which case he will appear in the zodiac at the point O. If now Saturn remained without any motion, when the earth arrives at B, he will be seen in the point of the zodiac L, and would appear to have described the arc OL, and to have moved according to the order of the signs from west to east. But because, while the earth is passing from A to B, Saturn likewise moves from E to M, where he is seen in conjunction with the sun, he will appear to have described the arc OQ greater than that OL. In this state the planet is direct, and its motion is from west to east, or according to the order of the signs. And its motion, now that it is in conjunction with the sun, and most remote from us, is quicker than at any other time.

The earth arriving in C, while Saturn describes the arc MG, he will be observed in the zodiac at R. But the earth being advanced to K, and Saturn to H, so that the line KH, joining the earth and Saturn, be for some time parallel to itself, or nearly so, Saturn will be seen all that time in the same point of the zodiac at P, and with the same fixed stars; and is therefore at this time stationary.

But the earth being come to D, and Saturn arrived in opposition to the sun in Z, he will appear in the zodiac in V, and will seem to have been retrograde, or to have gone backwards through the arc PV. Thus the superior planets, on optical considerations, are always retrograde, when in opposition to the sun.

The arc which the planet describes while thus retrograde, is called the *arc of retrogradation*.

The arcs of retrogradation of the several planets are not equal. That of Saturn is greater than that of Jupiter; that of Jupiter than that of Mars, &c.

RETROGRADATION of the Nodes, is a motion of the line of the nodes, by which it continually shifts its situation from east to west, contrary to the order of the signs; completing its retrograde circulation in the compass of about nineteen years: after which time, either of the nodes, having receded from any point of the ecliptic, returns to the same again. See NODES.

RETROGRADATION of the Sun. When the sun is in the torrid zone, and has his declination AM (*Plate XIX. Astronomy, fig. 13.*) greater than the latitude of the place AZ, but either northern or southern as that is, the sun will appear to go backwards, or to be retrograde both before

and after noon. This can never happen, without the tropics, in a natural way.

For, draw the vertical circle ZGN to be a tangent to the sun's diurnal circle in G, and another ZON through the sun's rising, in O, it is evident all the intermediate vertical circles cut the sun's diurnal circle twice; first, in the arc GO, and the second time in the arc GI. Wherefore, as the sun ascends through the arc GO, it continually arrives at farther and farther verticals. But as it continues its ascent through the arc GI, it returns to its former verticals; and, therefore, is seen retrograde for some time before noon. The same it may be shewn, after the same manner, it does for some time after noon. Hence, as the shadow always tends the opposite way to that of the sun, the shadow will be retrograde twice every day in all places of the torrid zone, where the sun's declination exceeds the latitude.

RETROGRADATION, or *Retrogression*, in the *Higher Geometry*, is the same with what we otherwise call *contrary flexion*. See FLEXURE and INFLEXION.

The general rule given by the marquis de l'Hôpital, for finding the point of reflection in curves whose ordinates are parallel, is the same as that for finding the point of contrary flexure, and consists in taking the second fluxion of the ordinate of the curve, and supposing it nothing or infinite: but this rule admits of many exceptions. See Maclaurin's Flux. b. i. c. 9. and b. ii. c. 5.

RETROGRADE, RETROGRADUS, formed from *retro*, backwards, and *gradior*, I go, something that goes backwards, or in a direction contrary to the natural one.

If the eye and the object both move the same way, but the eye much faster than the object, the object will appear to be retrograde, i. e. to go back, or to advance the contrary way from what it really does.

Hence it is that the planets, in some parts of their orbits, appear to be retrograde.

RETROGRADE order, in matters of numeration, is when, in lieu of accounting 1, 2, 3, 4, we count 4, 3, 2, 1.

RETROGRADE Verses are such as give the same words, whether read backwards or forwards: called also *reciprocal verses*, and *recurrents*. Such is

“Signa te signa; temere me tangis et angis.”

RETROGRADO, Ital. in *Music*, a retrograde motion of a melody, or subject of canon. This motion is sometimes termed by the Italians, *imitatione caneberrizante*; imitation of the movement of a crab-fish. See CANON.

RETROGRESSION, or RETROCESSION, the same with retrogradation.

RETROMINGENTS, compounded of *retro*, backwards, and *mingo*, I make water, in *Natural History*, a class or division of animals, whose characteristic is, that they stale backwards, both males and females. Such are lions, cats, &c.

RETROPANNAGIUM, RETROPANNAGE, in our *Ancient Latin Books*, after-pannage; or what is left when the bealls have done, or eaten the best. See PANNAGE.

“Et debent habere retropannagium a festo Sancti Martini usque ad festum Pur. Beatæ Mariæ.” Petit. in Parl. temp. Edw. III.

RETROSPECT, a look or view backwards. See RETROACTIVE.

RETROVERSIO UTERI, in *Surgery*. The womb is subject to two particular changes in the position of its fundus, which may be displaced either forwards or backwards. The first case, sometimes termed *anteversion*, is the least frequent; the second, or *retroversion*, is more often met with. In the instance of anteversion, when the surgeon makes an

## RETROVERSIO UTERI.

examination with his finger, he finds the fundus of the uterus inclining forwards towards the os pubis over the fundus of the bladder; while the os tincæ is carried backwards towards the sacrum, upon the middle of the rectum, sometimes so high up that it can hardly be reached with the finger. The patient has generally a constant inclination to make water; pressure just above the pubes always gives her considerable pain; whenever she gets up to walk, she is conscious of a hard substance falling upon the bladder, and obliging her to empty it; and, when she lies down upon her back, she feels the same hard body slip back again. In one example, a patient had such pain in the abdomen and soft parts, that she could scarcely move.

In general, the anteversion of the womb may easily be remedied. The patient being laid upon her back, which is to be somewhat raised up, the surgeon is to apply his hand above the pubes, and make pressure there, by which means the fundus uteri will be forced backwards, and the os tincæ inclined forwards into its natural situation. A recurrence of the displacement is to be prevented by the application of a pessary, which will support the os tincæ. The patient is to be kept for a certain time upon her back in bed, and a tight bandage should always be put round the body just over the os pubis. The uterus by degrees commonly becomes fixed again in its right position, so that the use of the pessary can be discontinued. The instrument must not be left off too soon, however, lest a relapse should be the consequence.

In the retroversion, the position of the womb is altered in a manner precisely the reverse of what occurs in the foregoing case. The os tincæ lies towards the pubes; while the fundus uteri is carried towards the sacrum, and is generally sunk so far down betwixt the vagina and the rectum, as to occasion, at the posterior part of the former canal, a protuberance, which closes it, and which at the same time compresses the rectum in such a manner, that the patient cannot void her feces, nor can clysters be administered. As in this preternatural position of the uterus, the bladder and meatus urinarius are unavoidably displaced, the case is always complicated with a retention of urine, which is the more afflicting, as it is usually very difficult, and even impracticable, to introduce a catheter. The opening of the meatus urinarius is sometimes drawn so high up, that it is actually higher than the pubes. Hence, the anterior parietes of the vagina are constantly very much stretched. When the retention of urine has lasted a certain time, the os tincæ above the pubes cannot be reached nor touched with the end of the finger. In this circumstance the bladder forms, beneath the os tincæ, a large swelling, which hinders the finger from feeling the latter opening. The patient always suffers excessive pain, which not unfrequently resembles that of labour, and arises partly from the impediment to the evacuation of the urine, and partly from the displaced condition of the parts. The disorder, therefore, has often been misunderstood, the patient's sufferings being regarded as labour-pains, and delivery expected. Indeed, when the complaint is not speedily removed, a miscarriage is the consequence. The case is frequently attended with fever and inflammation.

The retroversion of the uterus has never been observed, except in pregnancy, and always in the second, third, or fourth month of that state. It is most apt to occur in such women as have a wide pelvis. Fat subjects are more liable to the disorder than thin. It is observed to be brought on by bodily exercises and exertions, as, for instance, by violent vomiting, falls, the lifting of heavy burdens, &c. But, Richter thinks it unlikely, that the case should arise and be

suddenly produced by these causes alone. How, he asks, could the gravid, round, distended uterus be thus suddenly displaced, and become depressed betwixt the rectum and the vagina? He conceives it probable, that a predisposition to disorder, or rather an incipient stage of it, must have existed. He thinks it likely, that the occurrence of the complaint may be promoted by repeatedly neglecting to make water, and by the consequent distention of the bladder, whereby not only the fundus uteri is pressed towards the sacrum, but also the cervix becomes drawn upwards. Richter believes, that a small degree of retroversion, that has existed a good while, may only be increased by the causes already hinted at, so as to excite notice; and that the fundus of the uterus may now soon be forced by the efforts, resembling those of labour, so far down between the vagina and the rectum, that all these parts become as it were adherent together. The foregoing statement Richter thinks the more likely to be correct, inasmuch as cases have actually been observed, where patients have experienced various slight complaints a considerable time before the retroversion was known to exist; but which complaints might be ascribed to the incipient stage of that sort of displacement of the uterus. How it happens, that retroversion of this organ is only met with in the early months of pregnancy, is easy of comprehension. The retroversion is promoted by the weight of the gravid uterus. During the latter half of the period of gestation, however, the uterus is too large to be capable of descending betwixt the vagina and rectum; and the occurrence of retroversion, except in pregnancy, is what can hardly be conceived.

The surgeon should always endeavour to put the retroverted organ, as soon as possible, into its natural position again. The longer the retroversion has lasted, the more difficult it is of removal, and the more pressing are the dangers, of which there is cause for apprehension. The most urgent peril arises from the retention of the urine, and the stoppage of evacuations from the bowels. The longer these functions are obstructed, and the more the urine and feces accumulate, the more violent do the painful labour-like efforts become, whereby the fundus uteri is continually pressed more and more deeply downwards. Besides, the distention of the rectum and bladder operates itself as an immediate impediment to the reduction of the uterus. Patients have been known to lose their lives in consequence of the bladder giving way. Sometimes abortion happens; and very often the consequences of such an event are favourable; the urine soon afterwards being spontaneously voided, and all the complaints subsiding. (Saxtorph, *Collectanea Havniensia*, vol. ii.) The disorder, however, has been known to continue eleven days, and yet admit of being removed in the most favourable manner.

In difficult cases, the reduction of a retroverted uterus may be facilitated by previously emptying the rectum and bladder; an object which is frequently practicable. The distended bladder not only renders the reduction difficult, but is attended with some danger of that organ bursting in the operation, which often requires the exertion of considerable force, especially when the bladder is very much dilated. Hence, before attempting the reduction, the surgeon is called upon always to endeavour to draw off the urine. When the bladder has been emptied, the retroverted uterus sometimes spontaneously returns into its natural position, as several cases on record have proved. (Hunter and Chelton in *Medical Communications*, vol. ii.; Croft in *London Medical Journal*, vol. xi.) Such facts must fully convince us, how much the reduction may be facilitated by drawing off the urine in the first instance. A catheter may frequently

frequently be introduced; but it should be of the flexible sort. A curved inflexible one will also sometimes pass, if care be taken to keep its concavity turned towards the vagina. Rotating the catheter on its axis is here a particularly useful plan. When the catheter cannot be passed, other means will sometimes answer for bringing about an evacuation of the urine. In some cases, the water will begin to flow out, when two fingers are introduced betwixt the pubes and os tincæ, and the latter part is pressed towards the sacrum. Sometimes pressing the os tincæ downwards with the finger; on other occasions, raising the fundus uteri backwards and upwards, by means of two fingers in the vagina will have the desired effect.

When the bladder cannot be emptied in this manner, nor by the catheter, and should it be very much distended, and the reduction of the uterus attended with great difficulty, there can be no doubt about the necessity of puncturing the bladder; for the immediate and most urgent danger arises from the retention of urine, and, probably, the distended bladder is itself the chief impediment to the reduction of the womb into its natural position. To these considerations we may add, that the paracentesis of the bladder has been performed in these cases with complete success. (Chelton in Medical Communications, vol. ii.) The practitioner must also endeavour to empty the rectum by means of clysters, though, it must be confessed, their application is always attended with a degree of difficulty.

The reduction of the retroverted uterus is executed by pressing with two fingers applied to the fundus of this viscus. A principal obstacle to the success of the attempt is caused by the projection of the os sacrum. Hence, it is an indication of the greatest consequence to remove the fundus of a retroverted uterus as far as possible from that point, in order that the preceding sort of hindrance to the reduction may be avoided. With this view the pressure of the fingers should be so directed as not to incline towards the prominence of the sacrum. During the operation, the patient should rest upon her elbows and knees, as, in this position, the uterus will be at a greater distance from the sacrum. Richter disapproves of the plan, which some writers have recommended, and which consists in introducing two fingers into the vagina, for the purpose of reaching and drawing downwards the os tincæ. He asserts, that such part can seldom be reached, and, that if it could be so in a few instances, it would not admit of being drawn downwards, while the fundus is incapable of following in the same direction. Richter also observes, that the fundus uteri is at this period the less likely to be reduced, because the fingers in the vagina have the effect of pressing it towards the projection of the sacrum.

The pressure of the finger, whereby the fundus uteri is to be pushed up, should be directed forwards and upwards towards the navel. When the pressure is made directly upwards, the body of the uterus is forced against the projection of the sacrum, and the attempt cannot possibly succeed. Indeed, when much force is exerted, as is sometimes requisite, pressure thus directed may do injury to the fœtus and the mother, and bring on abortion. It is advantageous to introduce two fingers into the rectum, with their backs towards the sacrum, and their insides towards the vagina; for they may then be used for keeping the uterus towards the navel. Perhaps it may likewise be advisable to lay two fingers on the abdomen above the pubes, in order to prevent the os tincæ from inclining upwards. Perhaps, also, two fingers, passed into the vagina, might be usefully employed in pressing the fundus uteri upwards. In difficult cases, this double kind of pressure might be absolutely necessary. If

the retroverted uterus should not yield to the foregoing practice, an endeavour may be made, at all events, to push the displaced viscus upwards on one side of the projection of the sacrum.

In certain examples, it may be proper not to pass the fingers into the rectum, but merely into the vagina; 1st, because we can thus more certainly and effectually make the pressure act upon the uterus; and 2dly, because, when the posterior parietes of the vagina are pushed with the end of the fingers towards the sacrum, and the upper part of this tube, situated betwixt the fingers and the os tincæ, is stretched, the vagina acts upon the uterus in a manner particularly well calculated to promote the reduction. Not more than two fingers, however, ought to be introduced, as more have the effect of dilating the vagina laterally, and preventing it from becoming tense in the longitudinal direction. Theden's Bemerkungen, 3 Sheil.

When this method is adopted, the uterus in general begins to yield at first slowly, and afterwards it suddenly returns into its natural situation. Sometimes the tendency to retroversion is so great, that the disorder recurs almost immediately after the reduction has been accomplished. In this circumstance, the patient must wear a pessary, until all hazard of another retroversion is removed by the increase of pregnancy. (Hunter in Medical Observations and Enquiries, vol. iv.) Sometimes, when the bladder has been very much distended with urine during the continuance of a retroversion of the womb, a retention of urine from weakness of the bladder will remain after the reduction of the uterus, and demand the use of the catheter. Richter's Anfangsgrunde der Wundarzneykunst; Hunter in Medical Observations and Enquiries, vol. iv.; Chelton, in Medical Communications, &c.

RETSCHITZ KARDASCH, in *Geography*, a town of Bohemia, in the circle of Bechin; 15 miles S.W. of Tabor.

RETSCHITZ Rot, a town of Bohemia, in the circle of Bechin; five miles N. of Pilgram.

RETTEN, a town of the duchy of Stiria; 12 miles W. of Friedburg.

RETTERRHEIM, a town of the duchy of Wurzburg, insulated in Wertheim; 16 miles W. of Wurzburg.

RETTERSBACH, a town of the duchy of Wurzburg; five miles S. of Gemunden.

RETTERSWALD, a town of Prussia, in Pomerelia; seven miles S.E. of Marienburg.

RETTINGBERS, a town of Hindoostan, in Myfore; 38 miles E. of Chitteldroog. N. lat. 14° 5'. E. long. 77° 4'.

RETTLSTEIN, a town of Stiria, on the Muehr; six miles S.E. of Pruck.—Also, a mountain of Stiria; eight miles E. of Pruck.

RETTO, Ital. in *Music*, straight forward, direct, one of the three movements of musical notes or sounds in melody; which are, *moto retto*, *moto contrario*, and *moto obliquo*. *Moto retto* is, therefore, a regular ascent of the scale, or a part of it: as moving from the key-note to the 5th through all the intermediate sounds, in regular order; as c d e f g, &c. Another species of movement seems wanting to express wide intervals, such as skips or leaps beyond the regular progression, which in Latin is expressed by the words *per saltum*, and in Italian either is, or might be, called *moto de salto*.

RETIERTO, in *Geography*, a town of Spain, in Old Castile; 18 miles S. of Burgos.

RETURN, RETURNA, or *Retorna*, in *Law*, hath divers acceptations. As,

**RETURN of Writs** by sheriffs and bailiffs, is a certificate made to the court by the sheriff, bailiff, &c. of what is done with regard to the execution of the writ directed to them.

Whence the day, on which the defendant is ordered to appear in court, and on which the sheriff is to bring in the writ, and report how far he has obeyed it, is called the return of the writ; it being then returned by him to the king's justices at Westminster. And it is always made returnable at the distance of at least fifteen days from the date or teste, that the defendant may have time to come up to Westminster, even from the most remote parts of the kingdom; and upon some day in one of the four terms, in which the court sits for the dispatch of business. See **RETURNS**, *infra*.

Such also is the *return of a commission*, which is a certificate, or answer of what is done by the commissioners to whom such commissions, precepts, mandates, or the like, are directed,

**RETURN** is also used in case of a replevin. If a man distrain cattle for rent, &c. and afterwards justify or avow his act, so as it is found lawful, the cattle before delivered unto him that was distrained, upon security given to prosecute the action, shall now be returned to him that distrained them. See **RETURNO Habendo**, and **REPLEVY**.

**RETURN of Members of Parliament.** See **PARLIAMENT**.

**RETURN to a Mandamus.** See **MANDAMUS**.

**RETURNS**, *Return-days*, or *days in bank, dies in banco*, that is, days of appearance in the court of common pleas, usually called *bancum*, or *commune bancum*, to distinguish it from *bancum regis*, or the court of king's bench, are certain days in each term peculiarly set apart for the several kinds of proceedings in any cause to be determined. These days are generally at the distance of about a week from each other, and regulated by some festival of the church. On some one of these days in bank all original writs must be made returnable, and therefore they are commonly called the returns of that term; of which every term has more or less, said by the Mirror (cap. 5. § 108.) to have been originally fixed by king Alfred, but certainly settled as early as the statute of 51 Hen. III. stat. 2. But though many of the return-days are fixed upon Sundays, yet the court never sits to receive these returns till the Monday after; and, therefore, no proceedings can be had, or judgment can be given, or supposed to be given on a Sunday. See **DAY**.

Hilary term has four such returns; *viz. octabis Hilarii*, eight days after Hilary day; *quindena Hilarii*, fifteen days; *crastina Purificatione*, the day after the Purification; and *octabis Purificationis*, eight days after, inclusive.

Easter term has five returns; *viz. quindena Pasche*, fifteen days after Easter; *tres Pasche*, three weeks after; *mensis Pasche*, the day month after Easter; *quinque Pasche*, the day five weeks from Easter; and *crastino Ascensionis Domini*, the day after Ascension-day.

Trinity term has four returns; *viz. crastino Trinitatis*, the day after Trinity; *octabis Trinitatis*, eight days after, inclusive; *quindena Trinitatis*, fifteen days after; and *tres Trinitatis*, three weeks after.

Michaelmas term has four returns, by stat. 24 Geo. II. cap. 48. *viz. crastino Animarum*, morrow of All-Souls; *crastino Martini*, the morrow of St. Martin; *octabis Martini*, eight days after, inclusive; and *quindena Martini*, fifteen days after.

The first return in every term is, properly speaking, the first day in that term; *e. gr.* the octave of St. Hilary, which

falling on the thirteenth of January, the octave, or first day of Hilary term, is the twentieth of January; and this is called the *assign day of term*. But by reason of the *quarto die post*, the court does not sit, at the beginning of each term, for dispatch of business, till the fourth day, as in Hilary term on the twenty-third of January; and in Trinity term, by statute 32 Hen. VIII. cap. 21. not till the sixth day; which is, therefore, usually called and set down in the almanacs as the first day of *Term*; which see.

**RETURN**, in the *Military Language*, denotes the list of the sick, given in once a week by the surgeon to the commanding officer of a regiment.

Commissioned officers are not put in the returns, which, on that account, are but an imperfect list of the sick.

Twelve *sick*, in a battalion of 780 private men, is the lowest return that can be expected, even in the most healthy season and climate, as well as best quarters. Returns are often much higher, but seldom exceed seventy in a battalion.

It is to be observed, that returns include all accidents unfitting a soldier for duty; together with a general state of the army, regiment, or company. See Pringle's *Observ. on the Diseases of the Army*, p. 12—36.

In section V. of the articles of war, it is expressed, that every officer who shall knowingly make a false return to the king, to the commander-in-chief of the forces, or to any his superior officer authorized to call for such returns, shall, upon being convicted thereof before a general court-martial, be cashiered.

Whoever shall be convicted of having designedly, or through neglect, omitted sending such returns, shall be punished according to the nature of the offence by the judgment of a general court-martial.

Returns are to be made in the same manner of the forces in Ireland to the chief governor or governors thereof; likewise of the forces in North Britain to the officer there commanding in chief: which returns are from time to time to be transmitted to England as it shall appear best for the service.

Exact returns from Gibraltar, &c. and regiments stationed abroad, are by their respective governor or commanders *there residing*, by all convenient opportunities to be transmitted to the secretary at war, in order that the same may be laid before the king.

The life and foot-guards do not make any returns to the commander-in-chief or secretary at war, but to the king direct through their several field officers. This privilege is attached to them upon the principle of being household troops. Upon the same principle they have always, when brigaded, a general of their own attached to each brigade; on which account likewise, no other military honours than those done to their own brigade general are to be paid by them, except to a branch of the royal family, or to a commander-in-chief.

**RETURN, To**, in a military sense, to insert the names of such officers, &c. as are present or absent on the stated periods for the identification of their being with their regiments, on detachment, or absent with or without leave.

Every officer commanding a regiment or detachment, will, on his arrival from abroad, transmit to the adjutant-general's office, and to the war-office, a disembarkation return, a duplicate of which he will also deliver to the general, or other officer commanding at the port at which he disembarks.

Commanding officers of regiments in South Britain, are regularly to transmit to the adjutant-general's office the following returns.

A monthly, on the 1st of each month.

A return

A return of officers, on the 14th of each month.

A weekly state, to arrive on Mondays.

To the war-office.

A monthly return, on the 1st of each month.

A return of absent officers, on the 14th of each month.

Every officer commanding a regiment, or detachment, on embarking for a foreign station, will transmit an embarkation return to the adjutant-general's office, and to the war-office, a duplicate of which he will deliver to the general or officer commanding at the port from which he embarks.

On a regiment embarking, the commanding officer is to transmit to the adjutant-general's office, a return of the recruiting parties he purposes to leave in Great Britain, or Ireland, specifying their strength, their stations, and the officers by whom they are commanded; a duplicate of this return is to be transmitted to the inspector-general of the recruiting service in the Isle of Wight.

All officers belonging to regiments on foreign stations, not actually employed on the recruiting service, are to report their arrival from abroad, and the cause of their absence, at the adjutant-general's office, and are to leave their addresses with their respective agents, and in case of their changing their places of residence, are immediately to notice the same to their agent: any officer whose address is not with his agent, will be considered as absent without leave, and guilty of disobedience of orders.

Officers upon half pay are, in like manner, to leave their addresses at the war-office; particularly so if they should leave the united kingdoms; and officers belonging to the militia are to leave their names, &c. with the several adjutants of regiments.

Commanding officers of regiments are to transmit to the quarter-master-general an half-yearly return of quarters, on the 1st of December, and the 1st of May, agreeable to the printed form; likewise a report of any march performed by the corps under their orders.

All returns, reports, and papers, purely of a military and public nature, which are to be sent to the adjutant-general, are to be addressed, "To the Adjutant-general of the Forces, Horse-guards, London," without adjoining his name.

All official letters from general or other officers in command, which are designed to be laid before his royal highness the commander-in-chief, are to be signed by the general or commanding officers themselves.

All official letters, intended for the deputy adjutant-general, or other officers belonging to the department, are to be transmitted, under covers, addressed as above, to the adjutant-general.

To prevent an improper expence of postage, all official letters and returns sent to the quarter-master-general, or officers in his department, are to be sent, under covers, addressed "To the right honourable the Secretary at War, London;" and on the outside of the covers is to be written, in legible characters, "Quarter-master General's Department."

RETURN, in *Building*, denotes a side, or part, that falls away from the forehead of any straight work.

RETURNS of a *Trench*, in *Fortification*, are the turnings and windings which form the lines of a trench.

RETURNS of a *Mine*, in the *Military Art*, are the turnings and windings of the gallery.

RETURNED next for *Purchase*. When vacancies occur in regiments upon foreign or domestic stations, the names of such officers as intend to purchase must be inserted in the muster rolls; they are then said to be returned next for

*purchase*. This serves as a government to the several agents, and prevents the introduction of persons into a corps they have not done duty with, to the disparagement of those who have always followed the colours. The present commander-in-chief is particularly scrupulous on this head. Every officer that is returned next for purchase, must take care to apprise his agent that the money will be lodged for that purpose.

RETURNING STROKE, in *Electricity*, is an expression used by lord Mahon, (now earl Stanhope,) to denote the effect produced by the return of the electric fire into a body from which, in certain circumstances, it has been expelled.

In order to understand the meaning of these terms, it is necessary to premise that, according to the noble author's experiments, an insulated smooth body, immersed within the electrical atmosphere, but beyond the striking distance, of another body charged positively, is at the same time in a state of threefold electricity. The end next to the charged body acquires negative electricity; the farther end becomes positively electrified; while a certain part of the body, somewhere between its two extremities, is in a natural, unelectric, or neutral state; so that the two contrary electricities balance each other. Moreover, it may be added, that if the body be not insulated, or have a communication with the earth, the whole of it will be in a negative state; a certain portion of its natural quantity of electricity being driven into the common mass, by the pressure, repulsion, or other action of the electric matter belonging to the charged prime conductor. Let us then suppose a brass ball, which we may call A, to be constantly placed at the striking distance of a prime conductor; so that the conductor, the instant when it becomes fully charged, explodes into it. Let another large conductor, which we may call the second conductor, be suspended, in a perfectly insulated state, farther from the prime conductor than the striking distance, but within its electrical atmosphere; let a person standing on an insulated stool touch this second conductor very lightly with a finger of his right hand; while, with a finger of his left hand, he communicates with the earth, by touching very lightly a second brass ball fixed at the top of a metallic stand, on the floor, which we may call B; while the prime conductor is receiving its electricity, sparks pass (at least if the distance between the two conductors is not too great) from the second conductor to the insulated person's right hand; while similar and simultaneous sparks pass out from the finger of his left hand into the second metallic ball B, communicating with the earth. These sparks are part of the natural quantity of electric matter belonging to the second conductor, and to the insulated person, driven from them into the earth, through the ball B, and its stand, by the elastic pressure or action of the atmosphere of the prime conductor; the second conductor, and the insulated person, are hereby reduced to a negative state. At length, however, the prime conductor having acquired its full charge, suddenly strikes into the ball B, of the first metallic stand, placed for that purpose at the striking distance. The explosion being made, and the prime conductor suddenly robbed of its elastic atmosphere, its pressure or action on the second conductor, and on the insulated person, as suddenly ceases; and the latter instantly feels a smart returning stroke, though he has no direct or visible communication (except by the floor) either with the striking or struck body, and is placed at the distance of five or six feet from both of them. This returning stroke is evidently occasioned by the sudden re-entrance of the electric fire naturally belonging to his body and to the second conductor,

which

which had before been expelled from them, by the action of the charged prime conductor upon them, and which returns to its former place in the instant when that action or elastic pressure ceases. When the second conductor and the insulated person are placed in the densest part of the electrical atmosphere of the prime conductor, or just beyond the striking distance, the effects are still more considerable; the returning stroke being extremely severe and pungent, and appearing considerably sharper than even the main stroke itself, received directly from the prime conductor. Lord Mahon, in the application of this experiment, and of the doctrine deduced from it, observes, that persons and animals may be destroyed, and particular parts of buildings may be considerably damaged, by an electrical returning stroke, occasioned even by some very distant explosion from a thunder cloud; possibly at the distance of a mile or more. It is certainly easy to conceive (says a very ingenious anonymous writer, in his reflections on this subject) that a charged extensive thunder cloud must be productive of effects similar to those produced by the prime conductor. Like the conductor, while it continues charged, it will, by the superinduced elastic electrical pressure of its atmosphere, drive into the earth a part of the electrical fluid naturally belonging to the bodies which are within the reach of its widely extended atmosphere, and which will, therefore, become negatively electrical. This portion, too, of their electric fire will, on the explosion of the cloud at a distance, and the cessation of its action upon them, suddenly return to them, so as to produce an equilibrium, and restore them to their natural state. But the effects are not so great, nor the danger so terrible, as the noble author seems to apprehend. If the quantity of electric fluid naturally contained, *e. gr.* in the body of a man, were immense or indefinite, his lordship's estimate between the effects producible by a cloud, and those caused by a prime conductor, might be admitted; but surely an electrified cloud, how great soever may be its extent and the height of its charge, when compared with the extent and charge of a prime conductor, cannot expel from a man's body (or any other body) more than the natural quantity of electricity which it contains. On the sudden removal, therefore, of the pressure by which this natural quantity had been expelled in consequence of the explosion of the cloud into the earth, no more (at the utmost) than his whole natural stock of electricity can re-enter his body, provided he be so situated, that the returning fire of other bodies must necessarily pass through his body. But we have no reason to suppose that this quantity is so great, as that its sudden re-entrance into his body should destroy or even injure him.

In the experiment above described, the insulated person receives into his body, at the instant of the returning stroke, not only all that portion of his own natural electric fire which had been expelled from it, but likewise transmits through it, at the same instant, in consequence of his peculiar situation, all the electric fire of which the largest second conductor had been robbed, and which must necessarily re-pass through his body, to arrive at that conductor. To render the case somewhat parallel in natural electricity, the man's body must be so peculiarly circumstanced, supposing him to be in a house, that the electric matter which has been expelled from the house into the earth, by the pressure of an extensive thunder cloud, could not return back into the building, on the explosion of the cloud at a distance, without passing through his body: a case not likely to happen, unless the house were insulated (like the second conductor in the preceding experiment), and his body became the channel through which alone the house could have its electric

matter restored to it. It appears much more probable, that the electric matter returns to the house through the same channels by which it before insensibly passed out, and with equal silence, though more suddenly. In the case of a man who is abroad, and in an open field, during the time of an explosion; as he is unconnected with other masses of matter above him, no more than the precise quantity of electric fire, which had been before expelled from his body, will suddenly return into it at the instant of a distant explosion; and that this quantity is not very large, may be inferred from many considerations. Allowing, therefore, the existence of the returning stroke, as sufficiently ascertained, and well illustrated, in a variety of circumstances, by the author's experiments, the magnitude and danger of it are not so alarming as he apprehends. Lord Mahon's *Principles of Electricity*, &c. 4to. 1779, p. 76—113—131. *Monthly Review*, vol. lxii. p. 436—442.

RETURNO HABENDO, or *Returnum averiorum*, in Law, a writ which lies for him who has avowed a distress made of cattle, and proved his distress to be lawfully taken; for the return of the cattle distrained unto him, which before were replevied by the party distrained, upon surety given to pursue the action.

The same writ is granted when the plaint or action is removed by *recordare* or *accedas ad curiam*, into the court of common pleas; and he whose cattle were distrained makes default, and does not prosecute his action. See REPLEVY.

RETURNUM AVERIORUM, a judicial writ, the same with *retorno habendo*.

RETURNUM *Irreplegiabile*, a judicial writ, sent out of the common pleas to the sheriff, for the final restitution or return of cattle to the owner, unjustly distrained damage feasant, and so found by the jury before justices of assize in the county, or otherwise through default of prosecution.

RETUSAVI, in *Geography*, a name formerly given to a small island of Russia, in the gulf of Finland, on which the town of Cronstadt stands, and now called the isle of Cronstadt; 20 miles W. of Petersburg. This is only remarkable for an excellent haven, strongly fortified, the chief station of the Russian fleet.

RETUSUM FOLIUM, in *Botany*, a retuse, or abrupt, leaf, terminates bluntly, with a broad shallow notch, as in *Rumex dysynus*, or Mountain Sorrel. See LEAF.

RETWEYER, in *Geography*, a lake of Bavaria, in the bishopric of Bamberg; 6 miles N.E. of Vilseck.

RETZ, JOHN FRANCIS-PAUL DE GONDI, *Cardinal de*, in *Biography*, a celebrated political character, was born at Montmirel in 1614. His father, who was general of the galleys, obliged him, against his inclination, to embrace the ecclesiastical profession. He passed through his course of study with distinction, and was made a doctor of the Sorbonne in 1643, in which year he was nominated coadjutor to the archbishop of Paris. In his conduct and character he set at defiance public opinion, and engaged in almost every species of debauchery: he fought several duels, and delighted in political intrigue. According to Voltaire, he was, at the age of twenty-three, eager in carrying on a conspiracy against the life of cardinal Richelieu. The ministry of Mazarin, however, was the period in which he most engaged as a partisan, and he engaged deeply in all the cabals which produced the petty civil war of the Fronde. He imposed upon the people by a feigned devotional seriousness in performing his prelatial functions, and affected the greatest zeal for the privileges of the clergy and the good of the public. He was among the most violent opposers of the court, and once took his seat in the parliament with a poniard in his pocket, the handle of which being seen, it was neatly observed

observed, "there is our archbishop's breviary." He boasted that he had a principal share in urging the Parisians to take up arms on the day of *barricades*. At length, however, he found that the interests of his ambition would be better served by making a secret accommodation with the court, and he was brought over by a cardinalate, to which he was nominated by the king in 1651. Like other deserters, he lost his popularity, and was able only to act a secondary part on the political stage. Continuing his cabals, Mazarin, who hated and dreaded him, procured his arrest at the Louvre, and caused him to be thrown into prison. From the dungeon he escaped, and went to Rome, where he was received with distinction as the enemy of Mazarin. He was present at the election of Alexander VII., but finding that pontiff cool to his interests, he left Italy, and passed some years in wandering through Holland, Flanders, and England. Wearied with a life of exile, he returned to France in 1661, after Mazarin's death, and made peace with his court by the renunciation of his archbishopric, to which he had succeeded at the death of his uncle, obtaining the abbacy of St. Denis by way of recompence. He had hitherto lived in great style, and had plunged himself deeply in debt, but he now resolved to live on a very limited income, till he had satisfied his creditors. This he completely effected, and lived to be in circumstances that allowed him the gratification of being liberal to his necessitous friends. In 1675 he sent back his cardinal's hat, intending to quit the world, but the pope refused to accept his resignation. His conduct in the latter part of his life obtained for him the esteem of men of worth; he died at Paris in 1679, at the age of 66. The character of cardinal de Retz has been drawn by almost all the French historians who have written since his time. By one he is described "as a person who, with the habit of a priest, displayed a disposition better suited to camps or courts; and licentious in manners and profligate in his morals, he acquired an ascendancy over the minds of the people, without condescending to throw a veil over his vices, or employing the popular pretext of religion." Another writer says, he was "daring, turbulent, false, intriguing, with designs rather romantic than great, and conducted rather with dexterity than ability: he seems to have been exactly fitted for the part which he sustained, of a political meteor in troublesome times, among a frivolous and licentious people." Voltaire, speaking of the memoirs of the cardinal, drawn up by himself, says, "they are written with an air of greatness, an impetuosity of genius, and an inequality, which are the image of his conduct. He composed them in his retreat, with the impartiality of a philosopher, but of one who had not always been a philosopher. He neither spares himself nor others." Other writings of cardinal de Retz have been published relative to the times and party.

RETZ, in *Geography*, a town of Bavaria; 26 miles N.N.E. of Ratibon.

RETZBACH, a town of the duchy of Wurzburg; 4 miles S.S.E. of Carlstadt.

RETZIA, in *Botany*, an elegant Cape shrub, so named by professor Thunberg, in the Transactions of the Academy of Lund, in honour of his friend Andrew John Retzius, member of the Stockholm Academy, and of various other learned societies, Professor of Natural History at Lund. This distinguished botanist and worthy man is best known, out of his own country, by his folio volume of *Observations Botanicae*; and his *Flora Scandinaviae Prodrromus*, a systematic octavo work, in the Linnæan manner. He has, besides, published many essays and dissertations, relating to various branches of natural knowledge, both in Latin and Swedish.

and is still living.—Thunb. Act. Lund. v. 1. 55. Nov. Gen. 4. Linn. Suppl. 18. Schreb. 115. Willd. Sp. Pl. v. 1. 843. Mart. Mill. Dict. v. 4. Juss. 133. Lamarek Illustr. t. 103.—Class and order, *Pentandria Monogynia*. Nat. Ord. *Convolvuli*, Juss.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, tubular, in five rather deep, lanceolate, acute, unequal segments. *Cor.* of one petal, tubular, cylindrical, villous both within and without, terminating in five ovate, obtuse, concave, erect segments, very hairy at the summit. *Stam.* Filaments five, awl-shaped, inserted into the corolla, shorter than its limb; anthers arrow-shaped, compressed. *Pist.* Germen superior, oblong; style thread-shaped, longer than the corolla; stigma in two small, linear, obtuse segments. *Peric.* Capsule oblong, acute, with two lateral furrows, two cells and two valves. *Seeds* several, minute.

Ess. Ch. Corolla of one petal, cylindrical, externally hairy. Stigma cloven. Capsule of two cells, with many small seeds.

1. *R. spicata*. "Thunb. Act. Lund. v. 1. 55. t. 1. f. 2." Linn. Suppl. 138. Willd. n. 1. (*R. capensis*; Thunb. Nov. Gen. 5.)—Native of high, dry, hilly situations, at the Cape of Good Hope. Gathered by Mr. Niven in Hottentot's Holland. The stem is shrubby, erect, from four to seven feet high, with round, knotty, hairy, leafy branches. Leaves densely imbricated, somewhat whorled, sessile, linear-lanceolate, rigid, acute, thick-edged, entire, two inches or more in length; hairy about the lower part. Flowers axillary, sessile, solitary, plentiful towards the ends of the branches, about as long as the leaves; villous and hoary externally; dark purple within.

The remark of Linnæus the younger, in the Supplement, respecting this genus, is very extraordinary. He says "it is no natural genus, but agrees so much with *Convolvulus*, in habit and character, as to differ in nothing except the tubular corolla, which is externally very hairy." Now in fact, its rigid shrubby habit is altogether that of a *Protea*, nor can any thing be less like a *Convolvulus*, even of the shrubby kind. The character of the corolla is also most distinct, being cylindrical, and wanting the five plaits, so essential to *Convolvulus*. It is true that the *Retzia* requires to be observed by some botanist conversant with natural orders, that we might have clearer ideas of its characters and affinities. The plant is a stranger in our gardens.—We have not had an opportunity of consulting the Lund Transactions, to determine whether the specific name is there *capensis* as Thunberg, or *spicata* as Linnæus, cites it. Both are highly extensible.

RETZSTADT, in *Geography*, a town of the duchy of Wurzburg; 5 miles S.S.E. of Carlstadt.

RETZTAT, OBER, or *Upper*, a river of Franconia, which rises near Weissemburg, passes by Oettingen, and joins the Unter Retztat, to form the Rednitz.

RETZTAT, UNTER, a river of Franconia, which rises near Burg Bernheim, in the principality of Culmbach, and joins the Upper Retztat, three miles N.E. of Spalt, to form the Rednitz.

REVA, a town of Asiatic Turkey, in Natolia; 10 miles E. of Constantinople.

REUCHLIN, JOHN, in *Biography*, a celebrated German philosopher, and assiduous contributor to the revival of learning in the 15th and 16th centuries, descended from a respectable family in Swabia, was born in the year 1454. He made a most rapid progress in school-learning, and when that was completed, he went to Paris with the young marquis of Baden, who had been his class-fellow at school. Here he pursued his studies under the most celebrated masters

ters in Europe, and soon became well skilled in the Aristotelian philosophy. In this city, and in the diligent pursuit of learning, he remained till he was twenty years of age, when he went to Basil, where he was admitted a master in philosophy, and taught the Greek language to numerous pupils, with great reputation. Here he also prosecuted his study of the Hebrew, the elements of which he learnt while very young. At the same time, judging that the best manner of learning is by teaching, he drew up and published a grammar, a lexicon, and vocabulary, which at that period were highly esteemed, and thought to be of great use in instructing young people. Having spent four years at Basil, he went to Orleans for the purpose of studying jurisprudence, and he also taught the Greek language in that city. From this place he removed to Poitiers, where he was admitted to the degree of doctor. He next accompanied the count of Wittemberg in a tour through Italy, and was introduced at the court of Lorenzo de Medici, at Florence, and contracted an intimacy with Ficinus, Politian, Picus, and other illustrious Platonic philosophers, and was induced to embrace their opinions. In these opinions he was confirmed at Rome by the learned Hermolaus Barbarus, who, disliking the harshness of the German name Reuchlin, prevailed upon him to change it for one more musical, namely, CAPRIO, signifying, like *Reuchlin*, *smoke*, and by this he was afterwards known among foreigners. He conducted himself with so much ability and address in his tour, that he was, after his return to Germany, deputed as ambassador from the count of Wittemberg, to the emperor Frederic III. at Vienna. During his residence at this court, he made further progress in the Hebrew language, under the instructions of one of the emperor's physicians, who was a Jew; and it was contrived by the Jew, that among the presents which, according to custom, he was to receive as ambassador, should be included a beautiful and ancient manuscript Hebrew bible, as a special compliment paid to him by the emperor, on account of his eminent literary attainments. Frederic dying in 1493, Reuchlin returned to the court of Wirtemberg, and was appointed to be the count's deputy to the diet of Worms, in which his prince was elevated to the ducal dignity. Scarcely had he enjoyed that honour three months, when he died, leaving his dominions to his nephew Ulric. The power of this prince was contested by another nephew, who assumed the title of Eberhard II., and who carried the point. One of the first acts of this prince was to banish Reuchlin for his attachment to the interests of prince Ulric. He now retired to Worms, and wrote "An Epitome of the History of the four Empires," for the use of the prince Palatine. He also wrote at this time two Latin comedies, abounding with wit and satire, which were afterwards published. In 1498, the elector Palatine, having been involved in a dispute with pope Alexander VI., fixed upon Reuchlin as the person best qualified to defend his cause, and sent him for that purpose to Rome in the capacity of his ambassador. On this occasion he pronounced an able and eloquent oration before the pope and cardinals, concerning the rights of princes, and the privileges of the churches in Germany, which was printed by Aldus. Before he returned to Germany, a revolution had taken place at Wirtemberg, the usurper having been expelled, and Ulric reinstated in his rights. Upon this change, Reuchlin was recalled to the ducal court by the guardians whom the emperor had appointed for Ulric, and very soon after he was nominated to the dignity of one of the triumvirs of the league of Swabia for the emperor and the electors. He was next sent ambassador to the emperor Maximilian; and upon his return, finding the plague raging in Swabia, he retired to Stutgard, where he was hospitably

received into a monastery of the Dominicans, and at their request, he drew up a work on the art of preaching. Towards the close of his life he encountered much trouble and danger from the resentment of the monks and other bigots of Cologne, occasioned by his opposition to their enthusiastic rage for the destruction of all Jewish books excepting the bible. It is not necessary to enter at large into the nature of this controversy, it will be sufficient to observe, that Reuchlin found himself compelled to carry his cause to Rome, for the definitive sentence of the papal see. Here he had many friends, and his agent carried with him strong recommendations from princes, prelates, and men of the greatest eminence in the learned world. These recommendations had great weight in the court of Leo X., and Reuchlin was honourably acquitted of the heresy with which he was charged, to the great mortification of his bigotted and malignant enemies. Amidst the troubles which he met with he prosecuted his studies with unabated ardour, and published some very learned and profound works. Although, as we have seen, he triumphed over his enemies at the court of Rome, they did not cease to trouble him, by the invention of groundless calumnies, and the most bitter invectives; so that, notwithstanding his great talents, he was scarcely able, by teaching the Greek and Hebrew languages, to keep himself from want. He died in the year 1521, at the age of sixty-eight. His principal works, independently of those already noticed, are, "The Life of Constantine the Great," written by Eusebius: a treatise "De Verbo Mirifico," in the form of a dialogue between a philosopher, a Jew, and a Christian; and another treatise "De Arte Cabalistica." For his great and successful attempts towards the revival of learning, his name is deserving of being remembered with gratitude by posterity. His collection of "Letters from illustrious Men," of which an edition was published at Zurich in 1558, is said to be full of valuable information concerning the literary history of his time. Dupin speaks of him as one of the most learned men of that age; and he adds, that notwithstanding his attachment to his peculiar studies, he had a wonderful genius for the belles lettres; was intimately conversant with the Grecian philosophers and orators; was a perfect master of the Greek language, and spoke Latin with an inimitable purity and elegance; and that he was the only person of whom Germany at that time could boast, who deserved to be regarded as a competitor for fame with all the learned men in Italy, who was their equal in the delicacy of his style, while he greatly excelled them in erudition. Moreri. Dupin. Enfield's Hist. Phil. vol. ii.

REUDEN, in *Geography*, a town of Saxony; 5 miles N.W. of Bitterfeld.

REUDZEL, a river of European Turkey, which runs into the Reut, 18 miles W. of Florefctzi, in Moldavia.

REVE, or GREVE, in *Ancient Customs*, the bailiff of a franchise, or manor, thus called; especially in the western parts.

Hence, shire-reve, sheriff, port-greve, church-reve, &c. See SHERIFF, PORT-GREVE, &c.

REVE, *Reva*, is also used for a duty or imposition on merchandizes imported.

M. Du-Cange derives the word from the Latin *roga*, of *rogare*, to ask; the word formerly signifying a tribute anciently granted princes at their request, as a free gift.

REVEALED RELIGION. See RELIGION and REVELATION.

REVEALED *Theology*. See THEOLOGY.

REVEILLE, formed of the verb *reveiller*, to awake, a beat of drum in the morning, intended to give notice that it

is day-break; and that the soldiers are to arise, and the sentinels forbear challenging.

REVEL, in *Geography*, a town of France, and principal place of a district, in the department of the Upper Garonne; 21 miles N.W. of Carcassone. N. lat.  $43^{\circ} 28'$ . E. long.  $2^{\circ} 5'$ .—Also, a town of France, in the department of the Ille; 15 miles S.E. of Vienne.—Also, a sea-port town of Russia, on the Baltic, and capital of a province; the see of a Lutheran bishop, suffragan to the archbishop of Riga. Although this place be not large, it is opulent and well fortified; and has considerable trade. The town and castle were founded, in 1218, by Waldemar II., king of Denmark, on the site of the convent of St. Michael, founded by his ancestors, and in 1320 included within its walls. Revel, and also the whole duchy of Esthonia, received most of its privileges from the Danish kings; and the arms of Denmark, with inscriptions in the Danish language, are still seen in the churches and other public offices. The houses are generally built of brick, and the streets are somewhat regular. The only congregations here, besides those of the Russian church, are Lutheran. The tolls, belonging partly to the magistracy, and partly to the crown, are considerable. This town has its own arsenal, and maintains a number of matrosses, and a company of folders. Revel formerly held a distinguished rank among the Hanse towns, and it is still a staple-town, with a flourishing trade. Its harbour is spacious and convenient, and usually accommodates a part of the Russian fleet. It is surrounded with high walls, strengthened with bastions, and a deep ditch; and it is also fortified with a castle, seated on a rock, and ornamented with several towers. Without the walls the citizens have pleasant gardens. This city was erected into a bishopric by Waldemar II. It was totally destroyed by fire in 1433. In 1710 it was surrendered to Peter the Great, who confirmed its ancient privileges, and restored others of which it had been deprived by the crown of Sweden; 144 miles N. of Riga. N. lat.  $59^{\circ} 20'$ . E. long.  $24^{\circ} 34'$ .

REVEL'S *Island*, a small island near the coast of Virginia. N. lat.  $37^{\circ} 35'$ . E. long.  $75^{\circ} 43'$ .

REVE-LAND, the land which in *Domesday* is said to have been *thane-land*, and afterwards converted into *revel-land*, seems to be such land as, being reverted to the king after the death of the thane, who had it for life, was not since granted out to any by the king, but rested in charge upon the account of the *reve*, or bailiff of the manor. *Spelm, Feuds*, cap. 24.

REVELATION, REVELATIO, formed from *revelo*, of *re*, and *velum*, *q. d.* to unveil, the act of revealing, or making a thing public, which before was a secret, or unknown.

The revelation of a confession, made by the confessor, is adjudged, in the Romish church, to deserve the most exemplary punishment.

REVELATION is used, by way of eminence, for the discoveries made by God to his prophets, &c. and by them to the world.

REVELATION is more particularly used for the discovery which God has made to the world, by the mouths of his prophets, of certain points of faith and duty, which they could not learn from natural reason.

Religion is divided into natural religion and revelation, or revealed religion. See RELIGION.

By revealed religion, as distinguished from that which is usually called natural, we are to understand that knowledge of religion which was originally communicated in an extraordinary and supernatural way. A revelation of this kind must either be by an immediate infallible inspiration, or

illumination of every particular person, for informing and directing him with regard to the knowledge and practice of religion; or by God's making an extraordinary discovery of himself and of his will to some person or persons, who should be commissioned to communicate it to others in his name. In the former case it could not be properly called extraordinary revelation; for if it were an universal infallible light, imparted to every single person in every nation and every age, from the beginning of the world, it would be as common and familiar to every one as the common light of reason, and by being universal would cease to be extraordinary. Whereas, if there be such a thing as revealed religion, or if it hath pleased God to make discoveries of his will to mankind with respect to religious truth and duty, in a way of extraordinary revelation, the most natural mode of doing it, and that which is best accommodated to the present state of mankind, seems to be, that the revelation should be communicated to some person or persons, to be by them communicated to others in his name; at the same time furnishing them with sufficient proofs and credentials, to shew that they were indeed sent and inspired by him, and that the doctrines and laws which are the matter of such revelation, and which they are authorized to publish to the world in his name, were really and originally communicated by revelation from him. This method admits of sufficient proof being given to satisfy well-disposed minds, and of provision being made for instructing men, unless it be their own fault, in the knowledge of religion, and engaging them to the practice of the duties which it requires; and, at the same time, there is room for the exercise of reason in examining the nature of the evidence, and the trial of men's sincerity and diligence, of their impartial love of truth, and their openness to receive it.

Several questions present themselves to our consideration, with regard to that kind of revelation that has been now stated. The *first* relates to the possibility of it; the *second*, to its usefulness and expediency, and even the necessity of it in the present state of mankind; the *third* relates to the proofs and evidences, by which it may be shewn, that such a revelation hath been actually given.

As to the *first* question, the affirmative cannot reasonably be doubted by any one, much less denied, who believes a God and a Providence. Can it be supposed, that the Author of our being, and of our faculties, hath it not in his power to communicate ideas to our minds, for instructing and informing us in what it nearly concerns us to know?

It is acknowledged, even by lord Bolingbroke, a writer of distinguished rank among the opposers of revelation (*Works*, vol. ii. p. 463, ed. 4to.), "that an extraordinary action of God upon the human mind, which the word 'inspiration' is now used to denote, is not more inconceivable than the ordinary action of mind upon body, or body on mind;" and "that it is impertinent to deny the existence of any phenomenon, merely because we cannot account for it." Moreover, as God can, if he thinks proper, communicate his will to mankind, he can also do it in such a manner, as to give to those to whom it is originally and immediately made, a full and certain assurance of its being a true divine revelation. Besides, God can commission those to whom he has made an extraordinary revelation of his will, to communicate to others what they have received from him; and can furnish them with such credentials of their divine mission as are sufficient to prove that he sent them, and that the doctrines and laws which they deliver in his name were indeed received from God. The omnipotent Author of nature, and Lord of the universe, can undoubtedly, if he thinks fit, enable such persons to perform the most wonderful works in

## REVELATION.

his name, as a proof that he sent them; works of such a nature, and so circumstanced, as manifestly to transcend all human power, and bear the evident marks of a divine interposition. (See MIRACLE.) He can also endue them with supernatural gifts, and enable them to deliver express predictions of future contingent events, which no human sagacity could foresee, and which yet shall be accomplished in the proper season. (See PROPHECY.) It should also be further observed upon this subject, that not only they who live in the age when the revelation was first published to the world may have such proofs of it as may be sufficient to convince them of its divine authority and original, but that it may be transmitted with such evidence to those who live in succeeding ages, as may lay them under an obligation to receive and submit to it as a revelation from God. Although oral tradition is not a very sure conveyance, yet it is undeniable, that writings may be transmitted with such a degree of evidence as to leave no room for reasonable doubt. This is the most simple and natural way of propagating the knowledge of revelation to succeeding ages. Such is the fact with regard to the revelation contained in the holy scriptures: nor is it difficult to prove, that we have greater evidence of the safe transmission of these sacred writings, without any general and material corruption and alteration, than we have concerning other books, the genuineness of which is universally acknowledged. To this kind of argument it can only be objected, that moral evidence is uncertain, and historical human testimony fallible; but to the objection the reply is obvious, that this kind of evidence may be, and frequently is, so circumstanced, that the man would scarcely be thought in his senses who should seriously deny or doubt of it. It is by moral evidence, and the testimony of fallible men, capable of deceiving and of being deceived, that a man who has never been at Paris or Rome knows that there are such cities, and yet he can no more reasonably doubt of it, than if he had seen them with his own eyes. It is by moral evidence, that we have all our laws and records, and the assurance of any past facts. And yet is there any man of sense, who does not as certainly believe many facts which were done in former ages, as he believes any event that has happened of late years, and within his own memory? It is by this kind of evidence of testimony that we are necessarily guided and determined in many cases of great importance: and why should it be thought absurd to suppose, that it should be so ordered by the Author of our frame and the great Ruler of the world, that our knowledge of some important matters relating to religion should be obtained by this mode of conveyance? He that receives divine revelation upon this kind of evidence acts a wise and good part, becoming a reasonable being and a moral agent.

Having shewn that a revelation from God is possible, the second subject of consideration is the great usefulness and advantage of divine revelation, and the necessity of it in the present state of mankind, for supporting and promoting the interests of religion and virtue in the world. Such a revelation may be of great use even with regard to those truths and principles which lie at the foundation of all religion; such are the truths which relate to the excellent and unparalleled nature, the perfections and attributes of the one supreme God. (See GOD.) A divine revelation may also be very useful in establishing the belief of the providence of God; and further, in communicating instruction even to those, who allow that some kind of religious worship and homage should be rendered to God by his reasonable creatures. What kind of worship will be most acceptable to the Supreme Being, and what rites are most proper to be used in his service, are questions which unassisted reason cannot positively and

with certainty determine. The doctrine of the immortality of the soul, and of a future state of retribution, is unquestionably of very great importance to mankind; and the natural and moral arguments to prove it have certainly great weight; but they are assailed by difficulties and objections which weaken the evidence, and may occasion suspicion and doubt, if natural reason be our only guide and umpire. Accordingly some of the most eminent ancient philosophers either denied this doctrine, or expressed themselves doubtfully and waveringly concerning it. If then God himself should, by a well-attested revelation, assure us, that death shall not put an utter end to our being; that the present life is only the first stage of our existence; that we shall be raised again from the dead; and that God will call all men to an account, and reward or punish them in a future state according to their behaviour in this; and should also signify to us the nature of those rewards and punishments, and the qualifications of the persons on whom they shall be conferred or inflicted: this must needs be of high advantage, and tend to give us satisfaction in a point of considerable importance, for encouraging men in the practice of virtue, and delivering them from vice and wickedness. Moreover, we are led by the light of nature and reason to entertain some hope, that God will shew mercy to sinners upon their repentance and amendment; but how far this mercy shall extend, whether he will pardon sins of every kind, even the most heinous, frequently repeated, and long persisted in, merely upon repentance and amendment; and whether his pardon in this case will be only a mitigation or remission of the threatened penalty, without a full restitution to grace and favour, and how far he will reward an obedience attended with failures and defects:—these things might create anxious doubts and perplexities to serious and thoughtful minds. Especially when it is further considered, that reason leads us to regard God as just as well as merciful, a wise and righteous governor, who will therefore exercise his pardoning mercy in such a way as seemeth most fit to his rectoral wisdom, and will best answer the ends of moral government; and of this such short-sighted creatures as we are cannot pretend to be competent judges. A revelation from God satisfying mankind, and especially anxious penitents, with regard to these interesting questions, and assuring them by express promise, as well as by its representations of the placability of God, and of the provision which he has made for the pardon of repenting transgressors in perfect consilience with all the attributes of his nature and laws of his government, must be a very great benefit to the world. The assistance promised and certified by revelation, to those who use their own earnest endeavours in the performance of their duty, must further evince its importance and utility. Besides, the benefits of a divine revelation further extend to those laws and duties which we owe to God, our neighbours, and ourselves, and which are comprehended under the class of moral obligations. But though revelation is thus eminently useful, and even necessary, it is not designed to supersede the use of our own reason, or to render the exercise of it needless, but to guide, improve, and perfect it. Revelation, so far from discarding or weakening any argument that can be justly brought from reason, in proof of any truths relating to religion or morality, adds to them the attestation of a divine authority or testimony, which is of great weight. This both gives us a farther degree of certainty with regard to those things which are in some degree discoverable by the light of reason, and also furnishes us with a sufficient ground of assent, with respect to those things which mere unassisted reason, if left to itself, would not have discovered, and which yet it may be of use for us to know.

By the common consent of mankind, a competent authority is, in many cases, a good and proper medium to assure us of the truth of things; and to believe upon the credit of such an authority and testimony, is so far from being a renunciation of our reason, as some have pretended, that, on the contrary, it is what reason and good sense require; and to decline it would be to act an absurd and unreasonable part. Admitting that a supposed revelation from God is established upon sufficient evidence, we are bound to receive what is revealed upon the authority of the revealer; inasmuch that it would be a contradiction to believe it to be a revelation from God, and yet refuse our assent to it: since it is a most unquestionable principle, that, as God is incapable of deceiving or of being deceived, whatsoever he hath revealed must be true.

This leads us to the *third* subject of inquiry proposed in reference to divine revelation, *viz.* what are the proofs and evidences by which it may be known that such a revelation has been actually communicated to mankind, and that the revelation which we have in our possession is entitled to this character. We may observe in general, that it has been the sense of mankind in all ages and nations, that God hath made a revelation of his will to man; and this prevalent opinion has been probably derived from a tradition of some extraordinary revelation, or revelations, communicated in the earliest times to the first ancestors of the human race, from whom it has been transmitted to their descendants; though, in process of time, it has been in a great measure corrupted and lost. Or at least we may hence conclude, that men have generally thought that a revelation from God to man was both possible and probable; and that this was agreeable to the ideas they had formed of the wisdom and goodness of God, and of his concern for mankind. It would lead us far beyond the limits of this article, particularly to state the proofs that have been alleged for the divine authority of the Jewish and Christian revelation; both of which refer to and confirm the original revelation made to mankind from the beginning. But this is the less necessary, as the subject is discussed in various parts of the Cyclopædia. See BIBLE, CANON, CHRISTIAN Religion, RELIGION, RESURRECTION of Christ, SCRIPTURE, TESTAMENT, &c.

The Christian revelation is that made by Christ, and his apostles, in the New Testament. The Jewish revelation is that made by Moses and the prophets, in the Old Testament. See CHRISTIAN Religion, and JUDAISM.

A late author observes, somewhat invidiously, that it is the common method of all new revelations, to be built on precedent ones. Thus, the mission of Moses to the Israelites supposes a former revelation to Abraham, &c. The mission of Christ supposes that of Moses; and the pretended mission of Mahomet supposes the mission of Christ. The mission of Zoroaster to the Persians supposes the religion of the Magi, &c.

The general foundation of all revelation is this, that God is pleased man should know something relating to himself, his own nature, dispensation, &c. which the natural faculties with which he was pleased to create him could not attain to; and that he requires some duty or service at our hands, more than what necessarily follows from the relation we are under to him as our creator, preserver, &c.

This is also urged by deists, to the discredit of all particular revelations, as derogating from the perfections of God; such supplementary informations and instructions arguing, according to them, a prior deficiency in the established economy of nature, of which he is the author. But many able answers have been given to such cavils.

Particular or occasional revelations have their particular

geniuses, characteristics, and designs. That made by Moses and the prophets chiefly related to the nation of the Jews, considered as the descendants of Abraham: its design seems to have been to rescue that people from their slavery; to settle them in a new plantation; to give them a set of laws; to new-form their manners; to support them under difficulties and dangers of their enemies, from an opinion of their being under the immediate direction and appointment of God; to keep them from intermixing again with their neighbours, from an opinion of their being a chosen people, and of a Messiah to be born among them; and thus to preserve and transmit the knowledge of the unity of God, in opposition to idolatry and polytheism, and the hope of the Messiah, till the period of his appearance arrived. To some or other of these ends do all the Old Testament prophecies seem to tend.

The Christian revelation is founded on a part of the Jewish. The Messiah promised in the one is revealed in the other.

All the rest of the Jewish revelation, which related peculiarly to the Jewish people, is here set aside; and only that part of it in which the world in general was interested, and that relating to the advent, offices, and character of the Messiah, are retained.

Indeed, it must be owned, the Jews ever looked on this to be as peculiar to themselves as any of the rest; the Messiah was promised to them; he was to be their deliverer, their restorer, &c. and under this character he actually appeared. But, upon taking place of this new revelation, a new scene was opened, different from what many of them apprehended, because they misinterpreted the prophecies relating to the Messiah. The ceremonial part of their institution, local and temporary in its establishment and use, was abolished; and the Messiah appeared, not, as they erroneously imagined, to be the restorer of their civil sovereignty and liberties, which were now fallen into the hands of the Romans; but to restore and re-establish mankind in general, who had lost their original righteousnesses, and were become slaves of sin; to preach repentance and remission; and at last to suffer death, that all who believed in him might not die, but have everlasting life.

Such are the tenor and design of the Christian revelation, which, in the event, was so far from being what it had been apprehended to be by the people to whom it was first promised, that it proved the very reverse; and, instead of re-establishing and confirming the other branches of their revelation, it superseded, and set them all aside. The pale was now broken down, and the being of the seed of Abraham ceased to be a privilege, all the world being invited on the same terms with the Jews.

The consequence was, that the Jews, denying this to be the Messiah that had been promised to them, because their pride and prejudice prevented their discerning the accomplishment of their ancient prophecies in him, were generally excluded from the privileges of that mission, which they had vainly supposed to be not only primarily but wholly intended for themselves; and had their ruin completed from the very means whence they expected their redemption: because they expected a redemption, different in its nature from that which their own prophecies, fairly interpreted, proposed.

REVELLO, in *Geography*, a town of France, in the department of the Stura, near the Po, seated on the summit of a very high mountain, fortified both by nature and art. Having formerly served as a place of refuge for the marquis of Saluzzo, and withstood many attacks from their enemies, it was taken by the French; and in 1588 it surrendered to Charles Emanuel I., duke of Savoy. It contains one parochial church, and three other churches, a castle,

castle, a palace, and a convent of Dominicans; 3 miles N.W. of Saluzzo.

REVELS, formed from the French *reveiller, to awake*, as alluding to the night season, when they were chiefly held; entertainments of dancing, masking, gaming, acting comedies, farces, &c. anciently very frequent in inns of courts, at certain seasons, and in noblemen's houses, &c. but now much disused.

The officer who has the direction or ordering of the revels at court, is called the *master of the revels*.

REVELSKOI, in *Geography*, a province of Russia, so called from *Revel* the capital, bounded on the N. and W. by the Baltic, on the E. by the government of Petersburg, and on the S. by the government of Riga; about 144 miles in length, and from 16 to 60 in breadth; formerly the duchy of Esthonia. N. lat.  $58^{\circ} 20'$  to  $59^{\circ} 30'$ . E. long.  $23^{\circ}$  to  $28'$ . See ESTHONIA and REVEL.

REVENGE, in *Ethics*, is an insatiable desire to sacrifice every consideration of pity and humanity to the principle of vindictive justice. It renders the demands of that terrific giant paramount to every other claim. It is a propensity to retaliate evil, too fervent to be cooled by time, too deep and inveterate to be obliterated by concessions and intreaties. It anticipates joy in the contemplation of sighs and groans, and the only moment of transport is the instant of inflicting misery. This disposition approaches very near to permanent malevolence of the most despicable character. The abstract idea of justice, however, forms a partition between them; for to this, malevolence has no rightful claim. But its more honourable distinction consists in that repentance, which humanity excites in the mind that is not totally obdurate, after the gratification of this dreadful passion.

Anger long indulged to excess is apt to produce revenge. See ANGER.

REVENUE, the yearly rent or profits arising to a man from his lands, possessions, &c.

The word is French, formed from *revenir, to return*. Whence revenue is sometimes also used in ancient authors for a return; as the revenue of Easter.

The revenues of the English clergy were first fixed by king Ethelwulph, anno 853, who granted them for ever the tithe of all goods, and the tenth part of all the lands of England, free from all secular service, taxes, impositions, &c. Though Rapin observes, that tithes were settled on the clergy by the laws of Ina and Offa. But these laws were probably not observed, or perhaps Ethelwulph extended the law of tithes all over England. See TITHE.

The certain revenues of the king of England were anciently greater than those of any king in Europe; and till the time of the civil wars they enjoyed, in domains and fee-farm rents, almost enough to discharge all the ordinary expences of the crown, without any tax or imposition on the subject.

The revenue which the British constitution hath vested in the royal person, in order to support his dignity, and maintain his power, is either *ordinary* or *extraordinary*.

The king's *ordinary* revenue is such as hath either subsisted time out of mind in the crown, though, by reason of royal grants, the king be not at present in the actual possession of the whole of it; or else has been granted by parliament, by way of purchase or exchange for such of the king's inherent hereditary revenues, as were found inconvenient to the subject. Of the king's ordinary revenues there are four, which are of an ecclesiastical kind. Such are, 1. The custody of the temporalities of bishops, or all the lay revenues, lands, and tenements, (in which is in-

cluded his barony,) which belong to an archbishop's or bishop's see, and which, upon the vacancy of the bishopric, revert immediately to the king, as his right, during the vacancy. This branch of the royal revenue was formerly very considerable, but is now, by customary indulgence, reduced almost to nothing; for, at present, as soon as the new bishop is consecrated and confirmed, he usually receives the restitution of his temporalities, entire and untouched, from the king; and then, but not sooner, he has a fee-simple in his bishopric, and may maintain an action for the profits. (Co. Litt. 67. 341.) 2. A corody out of every bishopric, or a right of sending one of his chaplains to be maintained by the bishop, or to have a pension allowed him till the bishop promotes him to a benefice (F. N. B. 230.); which is now fallen into total disuse; though sir Matthew Hale says, that it is due of common right, and that no prescription will discharge it. 3. The tithes arising in extra-parochial places, which are held, indeed, under an implied trust, that the king will distribute them for the good of the clergy in general. (2 Inst. 647.) 4. The first-fruits and tenths of all spiritual preferments in the kingdom. See *FIRST-FRUITS* and *TENTHS*.

The following branches of the king's ordinary revenue are of a lay or temporal nature. 5. The first of these consists in the rents and profits of the demesne lands of the crown, which are either the share reserved to the crown at the original distribution of landed property, or such as came to it afterwards by forfeitures or other means, and were formerly very extensive, but are now contracted within a very narrow compass, having been almost entirely granted away to private subjects. 6. The advantages which used to arise to the king from the profits of his military tenures, to which most lands in the kingdom were subject, till they were in a great measure abolished by the statute 12 Car. II. cap. 24. to which may be also referred the profitable prerogative of purveyance and pre-emption; which branches of the royal revenue and power were resigned entirely by king Charles at his Restoration; in recompence for which, the parliament settled on him, his heirs and successors for ever, the hereditary excise of fifteen pence *per barrel* on all beer and ale sold in the kingdom, and a proportionable sum for certain other liquors; so that this hereditary excise forms the sixth branch of his majesty's ordinary revenue. 7. The rents payable to the crown by such persons as are licensed to sell wine by retail throughout England, except in a few privileged places, first settled on the crown by the statute 12 Car. II. cap. 25. but abolished by the statute 30 Geo. II. cap. 19. when an annual sum of upwards of 7000*l.* *per annum*, issuing out of the new stamp duties imposed on wine licences, was settled on the crown in its stead. 8. The profits arising from the king's forefests, consisting principally in ameracements or fines levied for offences against the forest-laws, for levying which, few, if any, courts have been held since 1632, 8 Car. I. 9. The profits arising from the king's ordinary courts of justice; consisting not only in fines imposed upon offenders, forfeitures of recognizances, and ameracements levied upon defaulters, but also in certain fees due to the crown in a variety of legal matters; as for setting the great seal to charters, original writs, and other forensic proceedings, and for permitting fines to be levied of lands in order to bar entails, or otherwise to insure their title. These, in process of time, have been almost all granted to private persons, or else appropriated to certain particular uses. All future grants of these, by 1 Ann. stat. 2. cap. 7. are to endure for no longer time than the prince's life who grants them. 10. The right to royal fish. 11. The revenue arising from shipwrecks, which

## REVENUE.

is frequently granted out to lords of manors, as a royal franchise. (See WRECK.) 12. The right to mines of silver and gold. (See MINE.) 13. The revenue of treasure-trove. 14. Waifs. 15. Estrays, which the law gives to the king as the general owner and lord paramount of the soil; though they now most commonly belong to the lord of the manor, by special grant from the crown. 16. Forfeitures of lands and goods for offences. (See CONFISCATE AND DEODAND.) These are for the most part granted out to the lords of manors, or other liberties. 17. The revenue arising from the escheats of lands, reverting, upon the default of heirs to succeed to the inheritance, to the king, who is esteemed, in the eye of the law, the original proprietor of all the lands in the kingdom. 18. The last branch of the king's ordinary revenue consists in the custody of idiots.

Such is the king's ordinary revenue, or the proper patrimony of the crown, which was formerly very large, and capable of being increased to a magnitude truly formidable: but, fortunately for the liberty of the subject, this hereditary landed revenue is now sunk almost to nothing; and the casual profits, arising from the other branches of the *census regalis*, are likewise almost all of them alienated from the crown. In order to supply the deficiencies of which, we are now obliged to have recourse to new methods of raising money, unknown to our early ancestors; which methods constitute the king's *extraordinary* revenue. See TAX, FUND, and NATIONAL Debt.

We shall here observe, that the aggregate fund stood mortgaged by parliament to raise an annual sum for the maintenance of the king's household, and the civil list. For this purpose, in the late reigns, the produce of certain branches of the excise and customs, the post-office, the duty on wine licences, the revenue of the remaining crown lands, the profits arising from courts of justice, (which articles include all the hereditary revenues of the crown,) and also a clear annuity of 120,000*l.* in money, were settled on the king for life, for the support of his majesty's household, and the honour and dignity of the crown. And, as the amount of these several branches was uncertain, (though in the last reign they were computed to have sometimes raised almost a million,) if they did not arise annually to 800,000*l.*, the parliament engaged to make up the deficiency. But his present majesty, soon after his accession, having accepted the limited sum of 800,000*l.* *per annum* for the support of his civil list, (charged also with three life-annuities, to the princes of Wales, the duke of Cumberland, and the princess Amelia, to the amount of 77,000*l.*) the said hereditary and other revenues were made a part of the aggregate fund, which was charged with the payment of the whole annuity to the crown of 800,000*l.* *per annum*. The expences formerly defrayed by the civil list were those that in any shape relate to civil government: as the expences of the household; all salaries to officers of state, to the judges, and each

of the king's servants; the appointments to foreign ambassadors; the maintenance of the queen and royal family; the king's private expences, or privy purse; and other very numerous outgoings, as secret service money, pensions, and other bounties; which sometimes have so far exceeded the revenues appointed for that purpose, that application has been made to parliament to discharge the debts contracted on the civil list; as particularly in 1724, when one million was granted for that purpose by the statute 11 Geo. I. cap. 17; and in 1769 and 1777, when half a million and 600,000*l.* were appropriated to the like use, by the statutes 9 Geo. III. cap. 34. and 17 Geo. III. c. 47. Many of these expences are now charged on the consolidated fund, and the civil list comprehends the support of his majesty's household.

The civil list is, indeed, properly the whole of the king's revenue in his own distinct capacity; the rest being rather the revenue of the public, or its creditors, though collected and distributed again in the name and by the officers of the crown.

The whole revenue of queen Elizabeth did not amount to more than 600,000*l.* a-year; that of king Charles I. was 800,000*l.*; and the revenue voted for king Charles II. was 1,200,000*l.*; but under these sums were included all kinds of public expence. The same revenue, subject to the same charges, was settled on king James II. (Stat. 1 Jac. II. c. 1.) But by the increase of trade, and better management, it amounted on an average to a million and a half *per annum*, (beside other additional customs, granted by parliament, (*ibid.* c. 3. and 4.) which produced an annual revenue of 400,000*l.*), out of which his fleet and army were maintained at the yearly expence of 1,100,000*l.* At this time the revenues of the king of France were computed at seven millions sterling; and those of the states of Holland at three millions. After the Revolution, when the parliament took into its own hands the annual support of the forces, both maritime and military, a civil list revenue was settled on the new king and queen, amounting, with the hereditary duties, to 700,000*l.* *per annum*; and the same was continued to queen Anne and king George I. That of king George II. was nominally augmented to 800,000*l.* (Stat. 1 Geo. II. c. 1.); and in fact was considerably more. But that of his present majesty was avowedly increased to the limited sum of 900,000*l.* The clear yearly sum of 100,000*l.*, to commence from the fifth of January 1777, over and above the sum of 800,000*l.* before granted, was granted to his majesty out of the aggregate fund by Stat. 17 Geo. III., but is now chargeable on the consolidated fund. Blackst. Com. vol. i. chap. viii. See FUND, and the sequel of this article.

The following particulars, relating to the revenue, are extracted from the Report presented to the house of commons, ending 5th January 1814.

# REVENUE.

An Account of the Ordinary Revenues and Extraordinary Resources constituting the Public Income of Great Britain,  
for the Year ending the 5th of January 1814.

Heads of Revenue.	Gross Receipt within the Year.	Total Sum to be accounted for, deducting outstanding Balances and Bills.	Net Produce applicable to National Objects, and to Payments to the Exchequer, deducting total Payments out of the gross Revenue.	Payments into the Exchequer, deducting total Payments out of the net Produce.

Her royal highness the princess Sophia, per 52 Geo. III. -	9,000	0	0
These, with other pensions, amount in the whole to -	1,595,350	6	11¾

For more particulars of this kind, see *POLITICAL Arithmetic, Public DEBTS, Public FUNDS, and TAX.*

REVENUE, *Auditors of the.* See AUDITOR.

REVENUE, *Court of.* See COURT of Exchequer.

REVENUE, *Officers of,* are excluded from voting in elections for members of parliament by 22 Geo. III.

REVENUE, *Revenu,* in *Hunting,* a fleshy mass or lump, formed chiefly of a cluster of whitish worms on the heads of deer, and supposed to occasion them to cast their horns, by those worms gnawing the roots of them.

The revenue distilled, is said to help women in travail.

REVENUE is also used for a new tail of a partridge, growing out after the loss of a former. The revenue is measured by fingers; thus they say, a partridge of two, three, and four fingers revenue.

REVERA, in *Geography,* a small island in the Adriatic, near the coast of Iliria. N. lat. 45° 15'. E. long. 13°.

REVERBERATION, REVERBERATIO, formed from *re,* and *verbero,* q. d. *I beat again,* in *Physics,* the act of a body repelling or reflecting another, after impinging on it. In the glass-men's furnace, the flame reverberates or bends back again to burn the matter on all sides. Echoes are occasioned by the reverberation of sounds from arched obstacles.

*Reverberation* and *resilition* refer to the same action; only the one to the agent, the other to the patient. A polished body reverberates the rays all around; the resilition of the rays does not arise from their striking against the solid parts of bodies. See REFLECTION.

REVERBERATION, in *Chemistry,* denotes a kind of circulation of the flame, by means of a reverberatory; or the return of the flame from the top of the furnace back to the bottom, chiefly used in calcination.

Reverberation is of two kinds. The first with a *close fire*; that is, in a reverberatory furnace, where the flame has no vent at top; being covered with a dome, or capital, which repels its action back on the matter, or the vessel that contains it, with increased vehemence.

After this manner are refining, the distillation of acid spirits, &c. performed.

Reverberation with an *open fire,* is that performed in a furnace, or reverberatory, whose registers are all open; used in calcination, &c.

REVERBERATORY, or REVERBERATING *Furnace,* is a chemical furnace built close all round, and covered at the top with a capital of brick or tiles, so as not to give any vent to the heat or flame, but to determine it to reverberate or turn back from the brick-work with new force, upon the matters placed at bottom.

When the fire has no vent or passage at top, it is a *whole* reverberatory; when the middle of the capital is open, and only the sides close, so that there is only a half circulation of the flame, it is called a *half* reverberatory.

The reverberating furnace is chiefly used in the fusion and calcination of metals and minerals, and on other occasions, where the most intense heat is required, as in assaying, &c. Whence it is also called the *melting-furnace,* and *assaying furnace.* See *Reverberating FURNACE.*

REVERENCE, in *Ethics,* is the veneration, or high degree of respect, which is paid to superior sanctity, intermixed with a certain degree of awe. It is the high respect paid to the sacred character of its object, attended with a conscious inferiority in moral worth.

REVEREND, REVERENDUS, a title of respect given to ecclesiastics.

The religious abroad are called reverend fathers; and abbesses, prioresses, &c. are called reverend mothers.

With us, bishops are *right reverend*; and archbishops *most reverend*. In France, their bishops, archbishops, and abbots, are all alike *reverendissimes, most reverend*.

REVERIE, a term purely French, frequently used of late in English, to signify a delirium, raving, or distraction. It is an ill sign in fevers when the patient falls into a reverie.

Hence also reverie comes to be used for any ridiculous, extravagant imagination, action, or proposition, a chimera or vision. Thus we say, authors obtrude abundance of their reveries upon us for solid truths.

But the most ordinary use of the word reverie, among English writers, is for a deep, disorderly musing or meditation, equivalent to what we popularly call a *brown study*. Thus, a little distraction I would allow; but for that continued series of reveries some people are guilty of who are ever absent from the place where you see them, and are never present any where, it is inexcusable.

REVERO, in *Geography*, a town of Italy, in the department of the Mincio, on the S. side of the Po, opposite to Ostiglio.

REVERS, BATTERY DE. See BATTERY.

REVERSAL, in *Law*. See REVERSE.

REVERSATA ARMA. See ARMA.

REVERSE, in the *Military Art*, signifies on the back, or behind. Thus we say, a reverse view, a reverse commanding ground, a reverse battery, &c.

REVERSE, formed of *re, again*, and *versus, turned*, in *Law*, &c. To reverse, signifies to undo, repeal, or make void.

A judgment may be reversed or voided for matters foreign to or *debors* the record, that is, not apparent upon the face of it, by writ of error, and by act of parliament. The effect of falsifying or reversing an outlawry is, that the party shall be in the same plight as if he had appeared upon the *capias*; and if it be before plea pleaded, he shall be put to plead to the indictment; if after conviction, he shall receive the sentence of the law; for all the other proceedings, except only the process of outlawry for his non-appearance, remain good and effectual as before. But when judgment, pronounced upon conviction, is falsified or reversed, all former proceedings are absolutely set aside, and the party stands as if he had never been at all accused; restored in his credit, his capacity, his blood, and his estates. But he still remains liable to another prosecution for the same offence. See ATTAINDER, JUDGMENT, and OUTLAWRY.

REVERSE of a medal, coin, &c. denotes the second, or back side; in opposition to the head or principal figure, called the face, or obverse.

F. Chamillart, a Jesuit, has an express dissertation on this point, whether or no the reverses of medals have always a regard to the emperors or empresses whose heads are represented on the front side of the medal? He says, that till of late the antiquaries have made no doubt of it; but that there are now several authors of another opinion.

The knowledge of the reverses of medals constitutes a distinguishing part of this science. In the early Greek coins, the reverse seldom affords much fancy of symbol; and in the imperial Greek coins it is chiefly impressed with temples of their deities. To Greek artists we are indebted for the beauty of the Roman imperial coins; and these are so highly finished, that on some reverses, as that of Nero's decurion, the "Adventus" and "Progressio" of various emperors, the "Fundator pacis" of Severus, the features of the emperor riding, or walking, are as exact as on the obverse. No Roman or Etruscan coins have been found of the globular form, or indented on the reverse, like the early Greek. The first

Greek are small pieces of silver, while the Roman are large masses of copper: the former are struck, the latter are cast in moulds. The reverses of Roman coins are very uniform, the prow of a ship, a car, or the like, till about 100 years before our era, when various reverses appear on their consular coins in all metals. See MEDAL.

With respect to the consular medals, it is observed, that the same reverse is common to many of them; as Castor and Pollux on horseback, first used; then a victory, or one of the gods; or the person to whose honour the medal was struck, driving a chariot with two or four horses; whence the denomination of the denarius *bigatus*, and *quadrigatus*. The ratis or ship, or prow of a ship, as an emblem of naval power, was no uncommon reverse on the consular coins; which were, on this account, called *ratiti*. Some of the consular medals, that bore on the face the impress of their ancient kings, preserved on the reverse the record of some worthy action which they had performed, as the famous aqueduct on the reverse of Ancus, in honour of his having begun it. Medals, struck on occasion of founding colonies, have sometimes on the reverse a priest following a yoke of oxen, with a plough; designed to denote the manner in which the boundaries of colonies were marked out, or that they were planted by the common people; and those trophies that are sometimes seen on medals of this kind, signify that they were planted by the veteran soldiers.

The reverses of imperial medals are very various; but the chief of them may be reduced to three classes, *viz.* figures or personages; public monuments or buildings; and inscriptions. The figures are sometimes those of princes in miniature, whose portraits are exhibited more at large on the face; as on the reverses of the emperors of the family of Constantine, we often see the emperor standing with a labarum in his right hand, and a globe, surmounted with a victory, in his left. Sometimes the emperor is disguised under the figure of some god; as on the reverse of a Dioclesian, who had assumed the name Jovius, he appears in the figure of Jupiter, sitting in a chair, with a globe in his hand, surmounted with a Victory; the legend being *IOVI. N. V. C. C. I. E. Hoc voluerunt consules*. The Greek coins of cities present us with exquisite heads of deities, apparently copied from statues or paintings. The majesty of Jupiter, the modesty of Diana, the beauty of Venus, the ferocity of Mars, and other ideal characters, appear in the Grecian civic coins with a perfection not to be surpassed by human art. Sometimes the figure on the reverse is some relation of that on the face; as Augustus on the reverse of Julius, and Claudius on the reverse of his mother Antonia. Such medals are highly esteemed by antiquarians, not only because it is a rule with them that every coin stamped with portraits on either side is very valuable, but because they identify the personage on the reverse to have been the wife, the son, or the daughter of such a particular prince, and thus help in the adjustment of a series. The figure of some deity is sometimes seen on the reverse; as Minerva on the reverse of a Domitian; and the goddesses Salus, with a patera in her hand, sacrificing to Esculapius, on the reverse of a Marcus Aurelius. (See MEDAL.) The virtues for which the emperors were, or wished to be, celebrated, are also frequently expressed by the figures on the reverses; and thus the fine personifications and symbols to be found on the reverses of the Roman coins render them entertaining, as well as instructive, to a person of poetical imagination. Virtue or Courage is represented by a bold armed woman with a spear in her right hand, and a parazonium in her left, on the reverse of a Domitian; Liberty, carrying in her right hand the cap of liberty, and in her left the wand called *rudis* or *vindicta*,

## REVERSES.

vindicta, appears on the reverse of a Commodus; and Equity, with a spear in her right hand, and a balance in her left, on the reverse of a Vespasian. The virtues of the ladies are also celebrated on the reverses of their medals; as Piety, in the habit of a Vestal virgin, strewing frankincense on an altar, on the reverse of a Faustina; Fœcunditas on another medal of the same, and SPES REIPUBLICÆ, expressed by a female figure, wearing a helmet to represent the republic, and two children at her breasts, on the reverse of a Maximiana Faustina, second wife of Constantine the Great. Happiness has sometimes the caduceus, or wand of Mercury, which Cicero (1 Offic.) tells us was thought to procure every wish. She has, in a gold coin of Severus, heads of poppy, to express that our chief bliss arises from oblivion of misfortune. Hope is represented as a sprightly damsel, walking quickly, and looking straight forwards. With her left hand she holds up her garments, that they may not impede the rapidity of her pace; while, in her right hand, she holds forth the bud of a flower, an emblem infinitely more fine than the trite one of an anchor, which is the symbol of patience, not of hope. This personification, with some others, must have been very familiar to the ancients, for often in this, and a few more instances, no name, as SPES AUG. or the like, is inserted in the legend. Abundance is imaged as a fedate matron, with a cornucopia in her hands, of which she scatters the fruits over the ground, nor does she hold up her cornucopia, and keep its contents to herself, as many modern poets and painters make her do. The emperor Titus, having cause to import a great supply of corn, during a scarcity at Rome, that supply, or the ANNONA, is finely represented as a fedate lady, with a full cornucopia in her left hand, which she holds upright, to indicate that she does not, however, mean to scatter it, as Abundance has a title to do, but to give it to Equity to deal out. This last circumstance is shewn by her holding a little image of Equity, known by her scales, and *hæsta pura*, or pointless spear, in her right hand, over a basket filled with wheat. Behind the ANNONA is the prow of a ship, decked with flowers, to imply that the corn was brought by sea, (from Africa,) and that the ships had had a prosperous voyage. The best poet in the world could not have given us a finer train of imagery; and the best painter would be puzzled to express so much matter in so small a compass. Security stands leaning on a pillar, indicative of her being free from all designs and pursuits; and the posture itself corresponds to her name. Horace, in describing the wise man, mentions his being “*teres atque rotundus*,” round and polished against all the rubs of chance;—an image seemingly derived from the column upon which this ideal lady reclines. The happiness of the state is pictured by a ship, sailing before a prosperous breeze;—an image, than which the superlative genius of Gray could not have found one more exquisite; and he has accordingly used it in his most capital production, “*The Bard*,” with due success.

Provinces are also represented by figures or personages, denoting either the emperor's conquest or care of them; as Judæa sitting in a melancholy posture at the bottom of a pillar adorned with trophies, to signify her captive state, on the reverse of a Vespasian; and Italia with a cornucopia in her right hand, to denote her fruitfulness; a crown of towers on her head, to represent her many cities; a sceptre in her left hand, and sitting on a globe, to shew that she was sovereign of nations, on the reverse of a Commodus. Britain is often represented, upon the earliest imperial coins, sitting on a globe, with a symbol of military power, the *labarum*, in her hand, and the ocean rolling under her feet:—an emblem almost prophetic of the vast power which her dominion over the sea will always give her, provided that

she asserts her element of empire with due vigour and perseverance, blending moderation and justice with her mighty power. On coins also we are presented with Achaia, Africa, Alamannia, Alexandria, Arabia, Armenia, Asia, Bithynia, Cappadocia, Dacia, Dardania, Egypt, Gallia, Hispania, Italia, Judæa, Macedonia, Mauritania, Pannonia, Parthia, Phrygia, Sarmatia, Sicily, Scythia, Syria, and the rivers Danube, Nile, Rhine, and Tiber. This personification of provinces, so interesting to the imagination, seems to have arisen from the figures of provinces carried in triumphs; as the personification of our old poets sprung from the ideal persons, actually represented in the mystical plays. Whilst we are on the subject of the poetical imagery of ancient coins, we must not omit the mention, even, of a colonial one and of rude execution, of Augustus and Agrippa, inscribed IMP. and DIVI F. which has a high claim to merit in this way. On the reverse the conquest of Egypt is represented by the apposite metaphor of the crocodile, an animal almost peculiar to that country, and at that period esteemed altogether so, which is chained to a palm-tree, at once a native of the country and symbolic of victory. Moreover, the figure on the reverse is sometimes designed to immortalize some worthy action of the emperor; as the goddess Moneta, with a cornucopia in her left hand, and a balance in her right, on the reverse of a Domitian, to denote his care about the public coin. There are sometimes two, three, or more figures, on the same reverse; as Honos and Virtus on the reverse of Galba; and three kings, with the emperor crowning them, on a medal of Trajan. (See MEDAL.) There are also the figures of animals on the reverses of some medals; as the eagle and peacock, to denote the apotheosis of princes and princesses; the crocodile, as the symbol of Egypt; a serpent, of Esculapius; a camel, of Arabia, &c.; and elephants in trappings on the reverse of an Antoninus Pius and a Severus, importing that these emperors procured these beasts to entertain the people at the public shows. We meet also with fabulous animals, as the griffin on the reverse of one medal of Gallienus, a centaur on another, and a phoenix on some medals of Constantine and his sons, denoting the perpetuity of the empire.

The second sort of reverses comprehends public monuments and buildings; as the temple of Janus shut, on the reverse of a Nero, to signify the universal peace he gave to the empire; the Macellum, or shambles, which he caused to be erected, on another; the sumptuous bridge built by Trajan over the Tiber, on the reverse of one of his medals; and the Amphitheatre and Naval Column, on those of Titus.

The third sort of reverses includes inscriptions on the table or field of the medal. On several Latin and Greek imperial medals, we find nothing on the reverse but S. C. or Δ. Ε. for *δημαρχικὸς ἐξουσιος*, inclosed in a crown. Others represent signal occurrences; as VICTORIA GERMANICA IMP. VI. COS. III. on the reverse of M. Aurelius. Others have titles of honour granted to the princes; as S. P. Q. R. OPTIMO PRINCIPI, on the reverse of a Trajan, and also of an Antoninus Pius. Other inscriptions again have respect to public vows, which were made for the emperor every ten years, or sometimes, in the lower empire, every five years. Thus we have on the reverse of a Constantius VOTIS XXX. MULTIS XXXX. importing probably their engagement to make new vows at the expiration of thirty years, that he might reign forty years.

Besides the reverses already enumerated, there are others, called by Addison riddles, which cannot be referred to any of the above classes. Thus, Mercury in the form of a Terminus, standing on a thunder-bolt, on the reverse of

an Augustus, was probably intended for a rebus, to express the sense of that emperor's motto, *festina lente*. Instruments of religion were symbols of the pontifex maximus, and signified the piety of the prince, on whose coin they appear; as the lituus, the simpulum, the asperforium, and the capula, on the reverse of a Nerva. Two hands joined, holding two ears of corn, and a caduceus betwixt them, on the reverse of a Titus, import the good harmony and union subsisting betwixt the prince and the public, the peace arising from such an union, and the plenty, which is the fruit of such a peace. Pinkerton on Medals, 2 vols. Addison's Three Series of Medals, in his Works, vol. i. p. 522, &c. See MEDALS.

REVERSE, in *Fencing*, a back-stroke.

REVERSED, in *Heraldry*, a thing turned backwards, or upside down.

REVERSED *Arms*, in *Military Language*, denote those whose butts are slung or held upwards.

REVERSED *Talon*, in *Architecture*. See TALON.

REVERSING, or RENVERSING, in *Music*, the inverting of the order of the parts; that is, placing the higher part, or treble, in the room of the lower part or bass.

Reversing is frequently practised in figurative counterpoint, where the bass serves as treble, and the treble at the same time as bass; and all this in such manner, as that the harmony, though very different, is yet as correct as before the reversing, when the parts were in their natural order.

A reversed fugue, or counter-fugue, called by the Italians *per contrarii movementi*, is when the guida falls, and the other, instead of imitating by falling, imitates by rising; or, it is a figure *per arsin et thesin*. See RENVERSÉ.

REVERSION, REVERSO, in *Law*, is defined by Coke, a returning of lands, &c. into the possession of the donor or his heirs, after the expiration of the term for which they were given or granted to another. Or, an estate in reversion, is the residue of an estate left in the grantor, to commence in possession after the determination of some particular estate granted out by him.

The word has a double acceptation. The first is, *jus revertendi, cum status possessionis defecerit*; which is no more than an interest in the land, when the occupation or possession of it shall fall.

The second is, when the possession and estate, which was parted with for a time, ceaseth, and is determined in the person of the alienee, assignee, grantees, or their heirs, or effectually returns to the donor, his heirs or assigns, whence it was derived.

This is the most proper signification of the word, which is derived from *revertor*: "Et apte dici non potest reversio, antequam revertatur in factum." Littlet.

The difference between a reversion and a remainder consists in this, that a remainder is general, and may remain or belong to any man but him that granteth or conveyeth the land, &c.

Whereas a reversion is to himself, from whom the conveyance of the land, &c. proceeded, and is commonly perpetual as to his heirs also. And yet sometimes reversion is confounded with remainder.

A reversion is never created by deed or writing, but arises from construction of law; a remainder can never be limited, unless by either deed or devise. But both are equally transferrable, when actually vested, being both estates *in presenti*, though taking effect *in futuro*. The usual incidents to reversions, the doctrine of which is derived from the feudal constitution, are said to be fealty and rent. When no rent is reserved on the particular estate, fealty however results of course, as an incident quite inseparable, and may be demanded as a badge of tenure, or acknowledged

ment of superiority, being frequently the only evidence that the lands are holden at all. Where rent is reserved, it is also incident, though not inseparably so, to the reversion. (Co. Litt. 143.) The rent may be granted away, reserving the reversion; and the reversion may be granted away, reserving the rent, by special words; but by a general grant of the reversion, the rent will pass with it, as incident to it; though by the grant of the rent generally, the reversion will not pass. The incident passes by the grant of the principal, but not *e converso*; for the maxim of law is, *accessorium non ducit, sed sequitur, suum principale*. Co. Litt. 151, 152.

The law has carefully distinguished remainders from reversions. Thus, if one seized of a paternal estate in fee makes a lease for life, with remainder to himself and his heirs, this is properly a mere reversion (Cro. Eliz. 321.), to which rent and fealty shall be incident; and which shall only descend to the heirs of his father's blood, and not to his heirs general, as a remainder limited to him by a third person would have done (3 Lev. 407.); for it is the old estate, which was originally in him, and never yet was out of him. And so, likewise, if a man grants a lease for life to A, reserving rent with reversion to B and his heirs, B hath a remainder descendible to his heirs general, and not a reversion to which the rent is incident; but the grantor shall be entitled to the rent during the continuance of A's estate. 1 And. 23.

For the assistance of those who have an estate in remainder, reversion, or expectancy, after the death of others, against fraudulent concealments of their deaths, it is enacted by 6 Ann. c. 18. that all persons, on whose lives any lands or tenements are holden, shall (upon application to the court of chancery and order made thereupon) once in every year, if required, be produced to the court or its commissioners; or, upon neglect or refusal, they shall be taken to be actually dead, and the person entitled to such expectant estate may enter upon and hold the lands and tenements, till the party shall appear to be living.

It may further be observed, that whenever a greater estate and a less coincide and meet in one and the same person, without any intermediate estate, the less is immediately annihilated; or, in the law phrase, is said to be merged, that is, sunk or drowned in the greater. Thus, if there be tenant for years, and the reversion in fee-simple descends to or is purchased by him, the term of years is merged in the inheritance, and shall never exist any more. But they must come to one and the same person in one and the same right; else, if the freehold be in his own right, and he has a term in right of another (*en autre droit*), there is no merger. Therefore, if tenant for years dies, and makes him who hath the reversion in fee his executor, whereby the term of years vests also in him, the term shall not merge; for he hath the fee in his own right, and the term of years in the right of the testator, and subject to his debts and legacies. So also, if he who hath the reversion in fee marries the tenant for years, there is no merger; for he hath the inheritance in his own right, the lease in the right of his wife. An estate-tail is an exception to this rule: for a man may have in his own right both an estate-tail and a reversion in the fee; and the estate-tail, though a less estate, shall not merge in the fee. For estate-tails are protected and preserved from merger by the operation and construction, though not by the express words, of the statute *de donis*: which operation and construction have probably arisen upon this consideration; that, in the common cases of merger of estates for life or years by uniting with the inheritance, the particular tenant hath the sole interest in them, and hath full power at any time

# REVERSION OF SERIES.

to defeat, destroy, or surrender them to him that hath the reversion; therefore, when such an estate unites with the reversion in fee, the law considers it in the light of a virtual surrender of the inferior estate. But in an estate-tail the case is otherwise: the tenant for a long time had no power at all over it, so as to bar or to destroy it; and now can only do it by certain special modes, by a fine, a recovery, and the like: it would, therefore, have been strangely improvident, to have permitted the tenant in tail, by purchasing the reversion in fee, to merge his particular estate, and defeat the inheritance of his issue: and hence it has become a maxim, that a tenancy in tail, which cannot be surrendered, cannot also be merged in the fee. Blackst. Comm. b. ii.

REVERSION of Series, in Algebra, is the method of finding the value of an unknown quantity, whose powers enter the terms of a finite or infinite series, by means of another series, in which it does not enter. Thus, if we have

$$y = ax + bx^2 + cx^3 + dx^4 + \&c. \text{ or}$$

$$y = ax^m + bx^{m+p} + cx^{m+2p} + dx^{m+3p} + \&c.$$

or if we have

$$ay + \beta y^2 + \gamma y^3 + \delta y^4 + \&c. =$$

$$ax + bx^2 + cx^3 + dx^4 + \&c.$$

and we can find in these, and other similar cases,

$$x = Ay + By^2 + Cy^3 + Dy^4 + \&c.$$

the original series is said to be reverted. The reversion of series was first proposed by Newton, in a letter to Mr. Oldenborough, at that time secretary to the Royal Society, with directions to have it communicated to Leibnitz, and

$$y = \left\{ \begin{array}{l} aAy + aB \\ + bA^2 \end{array} \right\} y^2 + \left\{ \begin{array}{l} aC \\ + 2BAB \\ + CA^3 \end{array} \right\} y^3 + \left\{ \begin{array}{l} aD \\ + 2bAC \\ + bB^2 \\ + 3cA^2B \\ dA^4 \end{array} \right\} y^4 + \left\{ \begin{array}{l} aE \\ + 2bad \\ + 2bBC \\ + 3cA^2C \\ + 3cAB^2 \\ + 4dA^3B \\ + eA^5 \end{array} \right\} y^5 + \&c.$$

Consequently we have  $aA = 1$ , and each of the other co-efficients equal to zero, it being a known property of two identical functions, that the co-efficients of the like powers of the indeterminate quantity are equal to each other; and since, on the first side of the above expression,  $y$  enters only simply, it follows, that all the powers of  $y$  on the other side must have their co-efficients equal to zero. Whence we have

$$aA = 1$$

$$aB + bA^2 = 0$$

$$aC + 2bAB + CA^3 = 0$$

$$aD + 2bAC + bB^2 + 3cA^2B + dA^4 = 0$$

$$\&c. \qquad \qquad \qquad \&c.$$

and hence, again, we have

$$A = \frac{1}{a}$$

$$B = -\frac{b}{a^3}$$

$$C = \frac{2b^2 - ac}{a^5}$$

$$D = -\frac{5b^3 - 5abc + a^2d}{a^7}$$

$$E = \frac{14b^4 - 21ab^3c + 3a^2c^2 + ba^2bd - a^4e}{a^9}$$

$\&c. \qquad \qquad \qquad \&c.$

in which the author gave one of the earliest proofs of his great analytical powers. It was afterwards published in his "Analysis per Equationes Numero terminorum Infinitas," and has since engaged the attention of many of the most profound analysts; and accordingly different methods have been suggested for this purpose; but that of M. Arbogatt, in his "Calcul des Derivations," is the most complete. We have already, under the article *Calculus of DERIVATIONS*, explained, as far as was consistent with the plan of this work, the nature of the symbols, notation, and principles of this doctrine; and we may, therefore, under the present article, give that author's formulæ for reversion, referring the reader for the first principles to the article above-mentioned. Still, however, as many of our readers would probably wish to see the same in its plainer English dress, we propose, in the first instance, to shew the methods commonly employed for this purpose by our own algebraists. This consists in assuming a series of a *proper form* for the required unknown quantity, and then substituting the powers of this series, instead of the powers of that quantity, in the proposed series, and finally equating the co-efficients, whereby the values of the indeterminate or unknown co-efficients, above represented by A, B, C, D, &c. will be obtained.

Let  $y = ax + bx^2 + cx^3 + dx^4 + ex^5 + \&c.$  be the proposed series, and

$$x = Ay + By^2 + Cy^3 + Dy^4 + Ey^5 + \&c.$$

the assumed reverted series; then, by substituting the several powers of this series, instead of the powers of  $x$  in that proposed, we have

And since  $a, b, c, d, \&c.$  are known in the original series, the numeral values of A, B, C, D, &c. in the reverted series are thus determined.

With regard to the *proper form* of the assumed series, we may observe, generally, that in order to find the first term of the reverted series, the rule is, to substitute  $y^n$  instead of  $x$  in the proposed series, and to equate the least power of  $y$  arising from this substitution with unity, which will give the required value of  $n$ ; and as for the indices of the other powers they will be the same multiples of the above value of  $n$ , as they are (in the original series) of unity.

Let there be proposed, for example,

$$z = x^m + bx^{m+p} + cx^{m+2p} + dx^{m+3p}, \&c.$$

Here, in order to determine the form of the series to be assumed, let  $z^n$  be wrote for  $x$  in the given equation, according to the usual method; and then the exponents, supposing  $z$  transposed, will be  $1, nm, nm + np, nm + 2np, nm + 3np, \&c.$  respectively; of which, the two least ( $1$  and  $nm$ ) being made equal to each other,  $n$  is found  $= \frac{1}{m}$ ; and

the differences are  $\frac{p}{m}, \frac{2p}{m}, \frac{3p}{m}, \&c.$  Whence the series to be assumed is

$$z = z^1 + Bz^{\frac{1+p}{m}} + Cz^{\frac{1+2p}{m}} + Dz^{\frac{1+3p}{m}} + \&c. \quad (\text{for}$$

# REVERSION OF SERIES.

(for it is evident, by inspection, that the co-efficient (A) of the first term must here be an unit).

This series being therefore raised to the several powers of  $x$ , in the given equation, and the co-efficients of the homologous terms in the new equation compared together, it will be found that,

$$B = -\frac{b}{m}$$

$$C = -\frac{(1+m+2p)b^2 - 2mc}{2m^2}$$

$$D = -\frac{(2m^2 + 9mp + 9p^2 + 3m + 6p + 1)b^3 + (1+m+3p)bc}{6m^3} - \frac{d}{m}, \&c.$$

$$\frac{(1+m+3p)bc}{m^2} - \frac{d}{m}, \&c.$$

From the general value of  $x$ , found above, innumerable theorems, for reverting particular forms of serieses, may be deduced.

Thus, if  $x + bx^2 + cx^3 + dx^4 \&c. = z$ ; then ( $m$  being  $= 1$ , and  $p = 1$ )  $x$  is  $= z - bz + (2bb - c)z^2 - (5b^3 - 5bc + d)z^3 \&c.$

And, if  $x + bx^3 + cx^5 + dx^7 + \&c. = z$ ; ( $m$  being  $= 1$ , and  $p = 2$ )  $x = z - bz^3 + (3bb - c)z^5 - (12b^3 - 8cb + d)z^7 \&c.$

Also, if  $x^2 + bx^3 + cx^5 + dx^8, \&c. = z$ ; then ( $m$  being  $= \frac{1}{2}$ , and  $p = 1$ )  $x = z^2 - 2bz^3 + (7bb - 2b)z^5 - (30b^3 - 18bc + 2d)z^8 \&c. \&c.$

It may be observed, that in all these forms of serieses, the first term is without a co-efficient (which renders the conclusion much more simple). Therefore, when the series to be reverted has a co-efficient in its first term, the whole equation must be first divided thereby.

Thus, if the equation was  $3x - 6x^2 + 8x^3 - 13x^4 \&c. = y$ ; by dividing the whole by 3 it will become  $x - 2x^2 + \frac{8x}{3} - \frac{13x^4}{3} \&c.$

$= \frac{1}{3}y$ ; where, putting  $z = \frac{1}{3}y$ , we have, by For 1.  $x = z + 2z^2 + \frac{16}{3}z^3 \&c. = \frac{y}{3} + \frac{2y^2}{9} + \frac{16y^3}{81} \&c.$

When there are two series, consisting of like powers of  $x$  and  $y$ , as

$$ax + bx^2 + cx^3 + \&c. = ay + \beta y^2 + \gamma y^3 + \&c.$$

assume, as in the preceding cases,

$$x = Ay + By^2 + Cy^3 + Dy^4 + \&c.$$

and let his, and its powers, be substituted for  $x$ , and the powers of  $x$ , and we shall have

$$ay + \beta y^2 + \gamma y^3 + \delta y^4 + \&c. = aAy + aB \left. \begin{matrix} y^2 + aC \\ bA^2 \end{matrix} \right\} y^2 + aC \left. \begin{matrix} + aD \\ + 2bAB \end{matrix} \right\} y^3 + aD \left. \begin{matrix} + 2bAC \\ + bB^2 \\ + 3A^2B \\ + dA^3 \end{matrix} \right\} y^4 + \&c.$$

in which, instead of equating all our co-efficients to zero, they must now be equated to  $\alpha, \beta, \gamma, \delta, \epsilon, \&c.$ ; that is

$$\begin{aligned} aA &= \alpha \\ aB + bA^2 &= \beta \\ aC + 2bAB + cA^3 &= \gamma \\ aD + 2bAC + bB^2 + 3cA^2B + dA^4 &= \delta \\ \&c. & \end{aligned}$$

Whence we have the following values of A, B, C, D, &c. viz.

$$A = \frac{\alpha}{a}$$

$$B = \frac{\beta - bA^2}{a}$$

$$C = \frac{\gamma - 2bAB - cA^3}{a}$$

$$D = \frac{\delta - bB^2 - 2bAC - 3cA^2B - dA^4}{a}$$

$$E = \frac{-2bBC - 2bAD - 3cAB^2 - 3cA^2C - 4dA^3B - eA^5}{a}$$

whence the values of A, B, C, D, &c. become determined as before.

In all the above cases, the several co-efficients  $a, b, c, d, \&c.$  are conceived to be totally independent of each other, and when this is the case, that is, when no specific law obtains between them, it is obvious, that we can proceed no farther in the practical solution than we have derived terms in the theoretical investigation; but if, as most commonly happens, the series we are desirous of reverting arise from the expansion of any function, so that an uniform law is observed between its several co-efficients; a similar law may frequently be discovered in the reverted series, though this generally depends rather upon an induction than from any peculiar form under which the reverted co-efficients arise, which is indeed the great imperfection of this method of reversion.

Let us take, for example, the series

$$x + \frac{x^2}{2} + \frac{x^3}{3} + \frac{x^4}{4} + \frac{x^5}{5} \&c. = z,$$

to find the value of  $x$  in terms of  $z$ .

This agrees with our first form; where  $a = 1, b = \frac{1}{2}, c = \frac{1}{3}, d = \frac{1}{4}, \&c.$  and we have

$$\frac{1}{a} = 1$$

$$-b = -\frac{1}{2}$$

$$+ (2b^2 - ac) = \frac{1}{2} = \frac{1}{3} = \frac{1}{6} = \frac{1}{2 \cdot 3}$$

$$- (5b^3 - 5abc + a^2d) = \frac{1}{24} = \frac{1}{2 \cdot 3 \cdot 4}$$

$$+ (14b^4 - 21a^2bc + 3a^2c^2 + 6a^2bd - a^3e) = \frac{1}{120} = \frac{1}{2 \cdot 3 \cdot 4 \cdot 5}$$

And hence, inferring the same law to have place throughout, we have

$$x = z - \frac{1}{2}z^2 + \frac{1}{2 \cdot 3}z^3 - \frac{1}{2 \cdot 3 \cdot 4}z^4 + \frac{1}{2 \cdot 3 \cdot 4 \cdot 5}z^5 - \&c.$$

We must not, however, look for the like uniformity of result in all cases. As an example of the contrary, let there be proposed the series

$$\begin{aligned} x - \frac{1}{2}x^2 + \frac{1}{2 \cdot 3}x^3 - \frac{1}{2 \cdot 3 \cdot 4}x^4 + \frac{1}{2 \cdot 3 \cdot 4 \cdot 5}x^5 - \&c. \\ = \frac{1}{2}y + \frac{1}{3}y^2 + \frac{1}{4}y^3 + \frac{1}{5}y^4 + \frac{1}{6}y^5 + \&c. \end{aligned}$$

to find  $x$  in terms of  $y$ .

Here  $a = 1, b = \frac{1}{2}, c = \frac{1}{2 \cdot 3}, d = \frac{1}{2 \cdot 3 \cdot 4}, \&c.$

$$\alpha = \frac{1}{2}, \beta = \frac{1}{3}, \gamma = \frac{1}{4}, \delta = \frac{1}{5}, \&c.$$

whence

$$\frac{\alpha}{a} = \frac{1}{2} = A$$

$$\frac{\beta - b A^2}{a} = \frac{11}{24} = B$$

$$\frac{\gamma - 2 b A B - c A^3}{a} = \frac{11}{24} = C$$

$$\frac{\delta - b B^2 - 2 b A C - 3 c A^2 B - d A^4}{a} = \frac{1381}{2880} = D$$

$$\frac{\epsilon - 2 b B C - 2 b A D - 3 c A B^2 - \&c.}{a} = \frac{1543}{3840} = E$$

whence the proposed series is

$$x = \frac{1}{2} y + \frac{11}{24} y^2 + \frac{11}{24} y^3 + \frac{1381}{2880} y^4 + \frac{1543}{3840} y^5 + \&c.$$

in which no law of continuation can be discovered, either by induction, or otherwise.

In this respect the symbols and notation of Arbogast have a decided advantage, as by these means the law of formation in the reverted series is exhibited in the clearest possible point of view. Taking for example our first series, under the form

$$y = \beta x + \gamma x^2 + \delta x^3 + \epsilon x^4 + \&c.$$

to find  $x = b y + c y^2 + d y^3 + e y^4 + \&c.$

Here the general result is expressed by

$$x = \beta^{-1} y + \frac{1}{2} \cdot D \cdot \beta^{-2} \cdot y^2 + \frac{1}{3} \frac{D^2}{C} \cdot \beta^{-3} \cdot y^3 + \frac{1}{4} \frac{D^3}{C^2} \cdot \beta^{-4} \cdot y^4 + \&c.$$

where the law is clearly expressed by means of the symbol D; and if it be requisite, the co-efficients may be easily expressed in terms of  $\beta, \gamma, \delta, \&c.$  thus  $\beta^{-1} = \beta^{-1}$ .

$$\frac{1}{2} D \cdot \beta^{-2} = -\beta^{-3} \gamma = \frac{-\gamma}{\beta^3}$$

$$\begin{aligned} \frac{1}{3} \cdot \frac{D^2}{C} \cdot \beta^{-3} &= \frac{1}{3 \cdot 2} \cdot D (-3 \beta^{-4} \cdot \gamma) \\ &= \frac{1}{3 \cdot 2} (-3 \cdot -4 \beta^{-5} \cdot \gamma^2 - 3 \beta^{-4} \cdot 2 \delta) \\ &= 2 \beta^{-5} \cdot \gamma^2 - \beta^{-4} \cdot \delta = \frac{2 \gamma^2 - \beta \delta}{\beta^5} \end{aligned}$$

$$\begin{aligned} \frac{1}{4} \cdot \frac{D^3}{C^2} \cdot \beta^{-4} &= \frac{1}{4} (D \beta^{-4} \cdot \frac{D^2}{C} \cdot \gamma + \frac{D^2}{C} \cdot \beta^{-4} \cdot D \cdot \gamma^2 \\ &\quad + \frac{D^3}{C^2} \cdot \beta^{-5} \cdot \gamma^3) \\ &= \frac{1}{4} (4 \beta^{-5} \cdot e + \frac{4 \cdot 5}{1 \cdot 2} \beta^{-6} \cdot 2 \gamma \delta \\ &\quad - \frac{4 \cdot 5 \cdot 6}{1 \cdot 2 \cdot 3} \beta^{-7} \cdot \gamma^3) \\ &= \frac{5 \beta \gamma \delta - 5 \gamma^3 - \beta^2 e}{\beta^7} \end{aligned}$$

which will be found to agree with our former result.

We refer the reader who may not be acquainted with the use and signification of the above symbols and notation, to our article DERIVATIONS.

In these formulae the quantities  $\beta, \gamma, \delta, \&c.$  although totally independent, are yet apparently connected by means of the symbol of derivation D; but the application is generally made to series which express the evolution of some function, and the co-efficients of which series are consequently formed after a certain law: for instance

$$1 + x + \frac{x^2}{1 \cdot 2} + \frac{x^3}{1 \cdot 2 \cdot 3} + \&c.$$

is the evolution of  $e^x$ , and if  $y$  be put

$$= 1 + x + \frac{x^2}{1 \cdot 2} + \frac{x^3}{1 \cdot 2 \cdot 3} + \&c.$$

then, by the theorem for reversion,

$$x = \beta^{-1} (y - 1) + \frac{1}{2} D \cdot \beta^{-2} \cdot (y - 1)^2 + \frac{1}{3} \frac{D^2}{C} \cdot \beta^{-3} \cdot (y - 1)^3 + \&c.$$

but in the proposed form

$$\beta = 1 \cdot D \cdot \beta = \frac{1}{1 \cdot 2} \cdot \frac{D^2}{C} \cdot \beta = \frac{1}{1 \cdot 2 \cdot 3}, \&c.$$

therefore  $x = (y - 1) - \frac{1}{2} (y - 1)^2 + \frac{1}{3} (y - 1)^3 - \&c.$

And in the same way from reversion, if

$$z = x + \frac{x^3}{2 \cdot 3} + \frac{3 x^5}{5 \cdot 8} + \&c.$$

by reversion  $x = z - \frac{z^3}{1 \cdot 2 \cdot 3} + \frac{z^5}{1 \cdot 2 \cdot 3 \cdot 4 \cdot 5} - \&c.$

We refer the reader for more on this subject to Woodhouse's "Principles of Analytical Calculation," and Arbogast's "Calcul des Derivations;" and for the principles of the method stated in the former part of this article, to Simpson's "Fluxions," vol. ii. p. 302; Maclaurin's Algebra, p. 263. See also Newton's "Analysis per Equations," and Bonnycastle's Algebra, vols. i. and ii.

REVERSIONS, in the *Doctrine of Annuities*, are either contingent or absolute. (For the former see the article SURVIVORSHIPS.) Of absolute reversions, the cases are very few, and the solutions simple and easy. An *absolute* reversion, whether it is to take place after the extinction of a single life, or of any number of lives, or after the expiration of a given number of years, must necessarily be more valuable, in general, than a *contingent* reversion; which, depending on events altogether uncertain, will be of less value in proportion as those events are less probable. The following problems include the principal cases of absolute reversions, and their solutions being almost self-evident, require no explanation.

PROBLEM I.

To find the value of the reversion in fee of an annuity after a given number of years.

*Solution.*—Deduct the value of an annuity for the given term from the perpetuity; multiply the remainder into the annuity, and the product will be the value required.

*Example.*—Let the annuity be 15l. the term 15 years, and the rate of interest 4l. per cent. By Tab. III. (see ANNUITIES) the value of an annuity for 15 years is 11.118, which being deducted from 25 (the perpetuity), the remainder, or 13.882, multiplied into 15 (the given annuity),

## REVERSIONS.

nunity), produces 208.23*l.* or 208*l.* 4*s.* 7*d.* nearly for the value required.

*Corollary.*—In like manner, the value of an annuity for a given term of years, after the expiration of another term, may be obtained by subtracting the value for the present term from the value during the present and reversionary terms: thus, the value of an annuity of 10*l.* during 15 years, after the expiration of 12 years, is found by subtracting 9.385 (the value for 12 years at 4*l.* per cent. by Tab. III. ANNUITIES) from 16.329 (the value by the same table for 27 years), and multiplying 6.944, the difference, into 10; which produces 69.440*l.* or 69*l.* 8*s.* 10*d.* nearly for the value required.

### PROB. II.

To find the value of the reversion in fee of an estate, or annuity, after the extinction of a given life.

*Solution.*—Deduct the value of an annuity on the given life from the perpetuity; multiply the remainder into the annual produce of the estate, or into the annuity, and the product will give the value sought.

*Example.*—Let the annual produce of the estate or annuity be 18*l.* the age of the possessor of such estate or annuity 35, and the rate of interest 3*l.* per cent. By Tab. VI. (LIFE-ANNUITIES), the value of an annuity on a life of 35, at 3*l.* per cent. is 15.938. The perpetuity, at the same rate, is 33.333; the difference between these two values, or 17.395, multiplied into 18, produces 313.110*l.* or 313*l.* 2*s.* 2*d.* for the answer.

*Corollary.*—The reversion in fee after two or three joint lives, or after the longest of two or three lives, is found in the same manner, by deducting the values of those lives from the perpetuity. Thus the value of two joint lives, aged 30 and 35, by Tab. VIII. (LIFE-ANNUITIES), at 3*l.* per cent. is 12.131, which being deducted from 33.333, and multiplied into 5, will give 106.01*l.* or 106*l.* 0*s.* 2*d.* for the value of the reversion in fee of an estate of 5*l.* per annum after the extinction of those joint lives. In like manner, the value of the reversion in fee of an estate of 10*l.* per annum, after three joint lives, aged 30, 35, and 40 years, and computing at 4 per cent. may be found by Prob. IV. (LIFE-ANNUITIES) to be 163.81*l.* or 163*l.* 16*s.* 2*d.*; and after the longest of those three lives, it may be found by Prob. V. (LIFE ANNUITIES) to be 59.980*l.* or 59*l.* 19*s.* 7*d.* nearly.

### PROB. III.

To find the value of a given sum, payable on the extinction of a given life.

*Solution.*—Deduct, as in the preceding problem, the value of an annuity on the given life from the perpetuity; multiply the remainder by the given sum, and divide the product by the perpetuity increased by unity; the quotient will be the answer.

*Example.*—Let the sum be 1000*l.* the age of the given life 45 years, and the rate of interest 5*l.* per cent. By Tab. VI. (LIFE-ANNUITIES), the value of an annuity, on a life of 45, at 5 per cent. is 11.105, which being deducted from 20, the perpetuity, leaves 8.895. This remainder, multiplied into 1000, and divided by 21, gives 423.571*l.* or 423*l.* 11*s.* 5*d.* for the value required.

In the same manner may be found the value of a given sum, payable on the extinction of two or three joint lives, or of the longest of two or three lives. Thus, the value of two joint lives, of 40 and 50, at 4 per cent. by Tab. IX. (LIFE-ANNUITIES), being 8.834; the difference between this value and 25, the perpetuity, will be 16.166; which being multiplied into 1000, and the product divided by 26, will give

621.77*l.* or 621*l.* 15*s.* 5*d.* for the present value of 1000*l.* payable on the extinction of those joint lives. Again, by the rule in the article on LIFE-ANNUITIES, and Tables VI. and IX. the value of an annuity on the longest of two lives, aged 40 and 50, at 4 per cent. may be found equal to 15.627, which being deducted from 25, and the remainder multiplied into 1000, will produce 9373, and this, divided by 26, will give 360.5*l.* or 360*l.* 10*s.* for the value of 1000*l.* payable on the decease of the survivor of those two lives.

*Remark.*—It will be observed, that the value of the reversion of an annuity is greater than the value of the reversion of a sum, in the proportion of 1*l.* increased by its interest for a year to 1*l.*; or, which is the same thing, in the proportion of the perpetuity increased by unity to the perpetuity. In the one case, the payment of the annuity becomes due at the end of the year, in which the life or lives become extinct; in the other case, the sum only becoming payable at the end of that year, the annual interest upon it cannot be received till the end of the succeeding year. See Dr. Price's Treatise on Reversionary Payments. Note E, Appendix.

### PROB. IV.

To find the value of an annuity for a given term of years after the extinction of any number of lives.

*Solution.*—Subtract the value of an annuity on the life or lives from the perpetuity; multiply the remainder into the present value of an annuity for the given term, and divide the product by the perpetuity; the quotient multiplied into the annuity will be the value sought.

*Example.*—Let it be required to determine the value of an annuity of 10*l.* for 20 years, which is not to commence till the extinction of a life of 25, reckoning interest of money at 5 per cent. By Tab. VI. (LIFE-ANNUITIES) the value of an annuity on a life of 25, is 13.567; this value, subtracted from 20, and multiplied into 12.4622, the value of an annuity for 20 years, by Tab. III. (ANNUITIES) produces 80.1693; which being divided by 20, and the quotient multiplied into 10, gives 40.085*l.* or 40*l.* 1*s.* 9*d.* nearly for the answer. By proceeding in the same manner, the value of an annuity of 15*l.* for 25 years, after the extinction of two joint lives, aged 30 and 40, and after the longest of those lives, computing at 4 per cent. may be respectively found to be equal to 136*l.* and 70*l.* 8*s.* 2*d.* by Tab. VI. and IX. (LIFE-ANNUITIES), and Tab. III. (ANNUITIES).

### PROB. V.

To find the value of an annuity after the decease of a given life, or of any number of lives, during the continuance of another life, or of any number of lives, to be nominated at the time of such decease.

*Solution.*—This differs very little from the preceding problem, and is answered much in the same manner. Subtract the value of an annuity, on the life or lives, from the perpetuity; multiply the remainder into the value of the life or lives at the time of their nomination, and also into the given annuity; divide the product by the perpetuity, and the quotient will be the answer.

*Example.*—Required the value of an annuity of 100*l.* after the decease of a person aged 30, during the continuance of the life of a person to be nominated at the time of such decease, whose age may be supposed to be then about 15 years, reckoning interest of money at 4*l.* per cent.

By Tab. VI. the value of a life of 30 is 14.781, which being subtracted from 25, and the remainder multiplied into 16.791 (the value by the same table of an annuity on

a life of 15), and also into 100, the given annuity produces 17.158.7. This sum, divided by 25, gives 686.34. or 636*l.* 6*s.* for the value sought.

If, instead of a single life of 30, the annuity had been to commence after the longest of two lives, aged 30 and 35, to continue during the longest of two lives, supposed to be 10 and 15 years of age at the time of the decease of the former lives, the present value in that case, at the same rate of interest, would be, according to the values in Tab. VI. and VIII. (*LIFE-ANNUITIES*), equal to 583.234*l.* or 583*l.* 4*s.* 8*d.* nearly. See Sumpson's *Select Exercises*; Dr. Price's *Treatise on Reverfionary Payments*; and Mr. Morgan's *Doctrine of Life Annuities*.

REVERT, in *Law*. A thing is said to revert when it returns or falls back to its first owner.

All honours and royal fees alienated revert to the crown, or are revertible. Apanages, or portions of younger fons of kings, are granted on condition of reverfion.

REVERTENS, Lat. returning or defcending: as, *Ducius revertens, conducimento, ritornante*, all imply a regular defcent of found; which the Italians likewise call *defcendente di grado*.

REVERTER, *Formedon in the*, in *Law*. See FORMEDON.

REVES, JAMES DE, in *Biography*, a learned Dutch Proteftant divine and profeflor, the fon of a Dutch burgo-mafter of Deventer, was born in 1586. While he was very young he was taken to Amsterdam, where he was instructed in the Latin, Greek, and French languages, and then sent to purfue his ftudies at the univerfity of Leyden. From this place he removed to the univerfity of Franeker, where he learned the Hebrew under the two Drufufes. In 1610 he travelled into France for farther improvement, where he refided two years, chiefly at Saumur, Rochelle, and Orleans. He next entered upon the duties of the Chriftian miniftry, and was, in 1641, chofen principal and firft profeflor of the theological college of the ftates of Holland and Weft Friefland at Leyden. He died at Leyden in 1658, at the age of 72. His works are very numerous, of which the titles are given in the *General Biography*: among thefe may be mentioned, “*Belgicarum Ecclefiafticarum Doctrina et Ordo*,” &c.; “*Historia Pontificum Romanorum contracta*, et ad Annum 1632 contracta;” “*Daventriae illuftratae, five Historiae Urbis Daventriae*, Lib. vi.” 1651, 4to. De Reves published an improved edition of “*The Book of Pfalms*,” in Dutch verfe, by Peter Dathenus, and he was concerned in revifing the Dutch verfion of the *Old Testament*, which was printed at Leyden in 1637.

REVELEMENT, in *Fortification*, is a ftrong wall built on the outside of the rampart and parapet, to fupport the earth, and prevent its rolling into the ditch. See CORDON.

REVEZ, in *Geography*, a town of Portugal, in the province of Tras os Montes; 10 miles N.E. of Lamego.—Alfo, a town of France, in the department of the Sambre and Meufe; 20 miles S. of Bruffels.

REUGNY, a town of France, in the department of the Indre and Loire; 9 miles N.E. of Tours.

REVIERS, a town of France, in the department of the Calvados; 8 miles N. of Caen.

REVIEW, in *Chancery*. A bill of review is where the caufe has been heard, and a decree therein figned and enrolled; but fome error in law appears in the body of the decree, or fome new matter is difcovered in time, after the decree made. A bill of review is not exhibited but by leave of the court.

A *commiffion of review* is a commiffion fometimes granted, in extraordinary cafes, to revife the fentence of the court of

delegates; when it is apprehended they have been led into a material error. This commiffion the king may grant, although the ftatutes 24 and 25 Hen. VIII. declare the fentence of the delegates definitive; becaufe the pope, as fupreme head by the canon law, ufed to grant fuch commiffions of review; and fuch authority, as the pope heretofore exerted, is now annexed to the crown by ftats. 26 Hen. VIII. cap. 1. and 1 Eliz. cap. 1. But this is not matter of right, which the fubject may demand *ex debito juffitiae*, but merely a matter of favour, and which, therefore, is often denied. See APPEAL.

REVIEW, in *Literary Hiftory*. See JOURNAL and MAGAZINE.

REVIEW, in *Military Language*, is the appearance of an army, or part of an army, arranged in form of battle, and exercifed, in prefence of the king or of a general. The firings in reviews are generally thirty-fix rounds, *viz.* by companies; by grand divifions; by fub-divifions; obliquely, advancing, retreating; by files; in the fquare; freet-firings, advancing and retreating; and, laftly, a volley.

The intention of a review is to know the condition of the troops, and to fee that they are complete, and that they perform their exercife and evolutions well.

REVIGNY, in *Geography*, a town of France, in the department of the Meufe, and chief place of a canton, in the diftrict of Bar-fur-Ornain; 15 miles S. of St. Menchould. The place contains 1800, and the canton 9087 inhabitants, on a territory of 162½ kilometres, in 17 communes.

REVILING *the Ordinances of the Church*, in *Law*, is an offence punifhable by ftatute. Thus it is provided by 1 Edw. VI. cap. 1 and 1 Eliz. cap. 1. that whoever reviles the facrament of the Lord's fupper fhall be punifhed by fine and imprifonment. See COMMON PRAYER.

REVILLA GIGEDO, in *Geography*, an ifland in the North Pacific ocean, nearly of an oval form, 50 miles long from N. to S., and 23 in breadth. Capt. Vancouver called it by this name from refpect to Coude de Revilla Ggedo, viceroy of New Spain. N. lat. 55° 6' to 55° 55'. E. long. 228° 27' to 229° 15'.

REVILLA Ggedo, *Canal of*, a ftrait of the North Pacific ocean, between the aforementioned ifland and that of Gravina.

REVILLY, a town of France, in the department of the Indre; 9 miles N. of Ifloudun.

REVIN, a town of France, in the department of the Ardennes, on the Meufe; 6 miles N.E. of Rocroy.

REVIINGHEIM, a town of France, in the department of the North; 5 miles N. of Bailloul.

REVISE, among *Printers*, a fecond proof of a fhcet to be printed, taken off after correctng the firft.

REVIVAL *of perfons hanged*. See EXECUTION.

REVIVER. See REVIVOR.

REVIVIFICATION, RESUSCITATION, or *Reduction*, in *Chemiftry*, the art of refloring a mixed body to its firft ftate, after it had been altered and difguifed by diffolution, calcination, and the like. See REDUCTION, and the feveral metals.

REVIVIFIED ANTIMONY. See ANTIMONY.

REVIVING, in *Law*, a renewing of rents and actions after they had been extinguifhed.

REVIVOR, or REVIVER, *Bill of*, is where a bill has been exhibited in chancery againft one who answers: but, before the caufe is heard, or at leaft before the decree is enrolled, one of the parties dies.

In this caufe, a bill of revivor muft be brought, praying the

the former proceedings may stand revived, and be put in the same condition as at the time of the abatement.

REUNION, *Isle de la*, in *Geography*. See BOURBON.

REVOCACTION, REVOCATIO, in *Law*, the act of revoking, calling back, or annulling, a power, grant, &c. made before.

The revocation of an offer, after it is accepted of, is invalid. All preceding wills or testaments are revoked by the last; but the republication of a former will revokes one of a later date, and establishes the first again.

The cancelling or revoking of a testament is one of the three ways of avoiding it. For, though I make a last will and testament irrevocable in the strongest words, yet I am at liberty to revoke it, because my own act or words cannot alter the disposition of law, so as to make that irrevocable which is in its own nature revocable. (8 Rep. 82.) For this, says lord Bacon (Elem. c. 19.) would be for a man to deprive himself of that which of all other things is most incident to human condition; and that is, alteration or repentance. It hath also been held, that without an express revocation, if a man, who hath made his will, afterwards marries and hath a child, this is a presumptive or implied revocation of his former will, which he made in his state of celibacy. (Ld. Raym. 441. 1 P. Wms. 204.) The Romans were also wont to set aside testaments as being "inofficiosa," deficient in natural duty, if they disinherited or totally passed by (without assigning a true and sufficient reason) any of the children of the testator. (Inst. 2. 18. 1.) But if the child had any legacy, however small, it was a proof that the testator had not lost his memory or his reason, which otherwise the law presumed; but was then supposed to have acted thus for some substantial cause; and, in such case, no "querela inofficiosi testamenti" was allowed. Hence probably has arisen that groundless vulgar error of the necessity of leaving the heir a shilling, or some other express legacy, in order to disinherit him effectually: whereas the law of England makes no such constrained supposition of forgetfulness or infamy; and, therefore, though the heir or next of kin be totally omitted, it admits no "querela inofficiosa" to set aside such a testament.

The revocation of a devise of lands and tenements must be in writing, signed by the testator, or some other person in his presence, and by his express direction; and be subscribed, in his presence, by three or four credible witnesses.

A prior claustral is revocable at pleasure. The revocation of the edict of Nantes was fatal to the French Protestants.

REVOCACTION of *Uses*. See USE.

REVOLAX, in *Geography*, a town of Sweden, in the government of Ulea; 13 miles E. of Brahestad.

REVOLSKOI, a town of Russia, in the government of Viborg; 128 miles N.W. of Povenetz.

REVOLUTION, formed from *revolvere*, to roll backwards, in *Politics*, denotes a grand turn or change of government.

There are no states in the world but have undergone frequent revolutions. The abbot de Vertot has furnished us with two or three good histories of the revolutions of Sweden, the revolutions of Rome, &c.

The REVOLUTION, used with us by way of eminence, denotes the great turn of affairs in England in 1688, when king James II. abdicating, the prince and princess of Orange were declared king and queen of England, &c. See *Right of Crown*.

The declaration of the prince of Orange, which was dispersed over the kingdom previously to his arrival, and which was received with universal approbation, contained an enu-

meration of the grievances of the nation, and the statement of which evinced the absolute necessity of a change in the government. These grievances were the dispensing and suspending power exercised by the king; the court of ecclesiastical commission; the filling of all offices with Catholics, and the raising of a Jesuit to be privy-counsellor; the open encouragement given to popery, by building every where churches, colleges, and seminaries for that sect; the displacing of judges, if they refused to give sentence according to orders received from court; the cancelling of the charters of all the corporations, and the subjecting of elections to arbitrary will and pleasure; the treating of petitions, even the most modest, and from persons of the highest rank, as criminal and seditious; the committing of the whole authority of Ireland, civil and military, into the hands of papists; the assuming of an absolute power over the religion and laws of Scotland, and openly exacting in that kingdom an obedience without reserve; and the violent presumptions against the legitimacy of the prince of Wales. The redress of these grievances was the prince's professed object; and for this purpose he proposed to have a loyal and free parliament assembled, in order to provide for the safety and liberty of the nation, as well as to examine the proofs of the prince of Wales's legitimacy. The prince, at the same time avowed, that he had no other design than to procure the full and lasting settlement of religion, liberty, and property. On the moment of alarm the English ministers redressed some of the grievances of which complaint had been made; but there still remained the foundation of all grievances upon which they could again in an instant be erected, an arbitrary and despotic power in the crown. For this usurpation there was no possible remedy, but by a full declaration of all the rights of the subject, in a free parliament. On the 21st of October 1688, the prince set sail from Helvoetsluys, with a fleet of near 500 vessels, and an army of above 14,000 men. A storm drove him back, but he soon repaired his loss, and made sail with a fair wind towards the west of England. The same wind detained the king's fleet in its station near Harwich, and enabled the Dutch to pass the straits of Dover without opposition. Both shores were covered with multitudes of people, who, besides admiring the grandeur of the spectacle, were held in anxious suspense by the prospect of an enterprize, the most important, which, during some ages, had been undertaken in Europe. The prince had a prosperous voyage, and landed his army safely in Torbay, on the 5th of November, (1688,) the anniversary of the gunpowder treason. The first person who joined the prince was major Buerington; and he was quickly followed by the gentry of the counties of Devon and Somerset. Sir Edward Seymour made proposals for an association, which every one signed. By degrees, the earl of Abingdon, Mr. Ruffel, son of the earl of Bedford, Mr. Wharton, Godfrey, Howe, came to Exeter. All England was in commotion. Lord Delamere took arms in Cheshire, the earl of Danby seized York, the earl of Bath, governor of Plymouth, declared for the prince, and the earl of Devonshire made a like declaration in Derby. The nobility and gentry of Nottinghamshire embraced the same cause; and every day there appeared some effect of that universal combination into which the nation had entered against the measures of the king. Even those who took not the field against him, were able to embarrass and confound his counsels. A petition for a new parliament was signed by 24 bishops and peers of the greatest distinction, and was presented to the king. No one thought of opposing or resisting the invader. The army deserted him; and several officers of distinction informed Feversham, the general, that they could not in conscience fight

fight against the prince of Orange. Prince George of Denmark and the princess Anne abandoned the king: an event which, concurring with several other incidents that had occurred, and which threatened the overthrow of his royal authority, occasioned an alarm approaching to consternation, and a grief that caused him to shed tears. In this state of distress, deserted by his friends and family, and despised by his enemies, he was as much depressed, as he had before been vainly elated by prosperity. He issued writs for a new parliament, and deputed commissioners to treat with the prince of Orange. The king every day more and more alarmed by accounts of the general disaffection that prevailed, and misled by imprudent counsel operating upon his fears, precipitately embraced the resolution of escaping into France, having sent before him the queen and the infant prince. Nor before his departure did he provide for the exercise of the administration; he threw the great seal into the river, and recalled all the writs that had been issued for the election of the new parliament. During this temporary dissolution of government, the populace became matters, rose in a tumult, destroyed the mans-houses, and even attacked and rifled the houses of the Florentine envoy and Spanish ambassador, where many Catholics had lodged their valuable effects. Having discovered Jefferies, the chancellor, notwithstanding the disguise he had assumed in order to fly the kingdom, they so abused him that he died soon after. Feversham disbanded the troops, and without either disarming or paying them, let them loose to prey upon the country. In this extremity, the bishops and peers, who were in town, assembled, and having chosen the marquis of Halifax speaker, gave directions to the mayor and aldermen for keeping the peace of the city, and issued orders, which were readily obeyed, to the fleet, the army, and all the garrisons; and they made applications to the prince of Orange, whose enterprize they highly applauded, and whose success they joyfully congratulated. The prince, availing himself of the popularity of his cause, approached nearer and nearer to London. In the mean while the king, though disguised, was discovered and seized by the populace at Feversham, where he was attempting to make his escape, and soon after arrived in London. Whilst he remained at Whitehall he received few marks of attention and respect; and whilst he remained there the Dutch guards took possession of the palace. In consequence of a message conveyed to him from the prince by Halifax, Shrewsbury, and Delamere, which commanded him to leave the palace, he removed to Ham, a seat of the duchess of Lauderdale's. Having obtained permission he retired to Rochester, where he remained for some days. But finding that the church, the nobility, the city, the country, all concurred in neglecting him, and leaving him to his own counsels, he submitted to his melancholy fate; and being urged by earnest letters from the queen, he privately embarked on board a frigate which waited for him; and he arrived safely at Ambleteuse in Picardy, whence he hastened to St. Germain's. The prince, in compliance with an address from about 90 peers and bishops, summoned a convention, which completed the revolution.

The true ground and principle upon which that memorable event proceeded, was an entirely new case in politics, which had never before happened in our history; the abdication of the reigning monarch, and the vacancy of the throne thereupon. Accordingly, in a full assembly of the lords and commons, met in *Convention* (which see) on occasion of this vacancy, both houses came to this resolution (Jan. 22, 1689): "That king James the Second, having endeavoured to subvert the constitution of the kingdom, by breaking the original contract between king and people; and, by the advice

of Jesuits, and other wicked persons, having violated the fundamental laws; and having withdrawn himself out of this kingdom, has abdicated the government, and that the throne is thereby vacant."

The facts themselves thus appealed to, *viz.* the king's endeavour to subvert the constitution, by breaking the original contract, his violation of the fundamental laws, and his withdrawing himself out of the kingdom, were evident and notorious: and the consequences drawn from these facts (namely, that they amounted to an abdication of the government (see *ABDICATIO*); which abdication did not affect only the person of the king himself, but also all his heirs, and rendered the throne absolutely and completely vacant) it belonged to our ancestors to determine. For, whenever a question arises between the society at large and any magistrate vested with powers originally delegated by that society, it must be decided by the voice of the society itself: there not being upon earth any other tribunal to which to resort. And that these consequences were fairly deduced from these facts, our ancestors have solemnly determined, in a full parliamentary convention representing the whole society. The reasons upon which they decided may be found at large in the parliamentary proceedings of the times, our ancestors having most indisputably a competent jurisdiction to decide this great and important question, and having in fact decided it, it is now become our duty at this distance of time to acquiesce in their determination; being born under that establishment which was built upon this foundation, and obliged, by every tie, religious as well as civil, to maintain it.

The lords and commons having determined this fundamental article, that there was a vacancy of the throne, proceeded to fill up that vacancy in such manner as they judged the most proper. And this was done by their declaration of the 12th of February, 1689, in the following manner: "That William and Mary, prince and princess of Orange, be, and be declared king and queen, to hold the crown and royal dignity during their lives, and the life of the survivor of them; and that the sole and full exercise of the regal power be only in, and executed by, the said prince of Orange, in the names of the said prince and princess, during their joint lives; and after their deceases the said crown and royal dignity to be to the heirs of the body of the said princess; and for default of such issue, to the princess Anne of Denmark, and the heirs of her body; and for default of such issue, to the heir of the body of the said prince of Orange." This transaction, founded in equity, and strictly agreeable to the spirit of our constitution, and the rights of human nature, formed a new era in the history of our country, in which the bounds of prerogative and liberty have been better defined, the principles of government more thoroughly examined and understood, and the rights of the subject more explicitly guarded by legal provisions, than in any other period of the English history.

To the settlement of the crown was annexed a declaration of rights, in which all the points that had, of late years, been disputed between the king and people were finally determined; and the powers of royal prerogative were more narrowly circumscribed and more exactly defined than in any former period of the English government. It is worthy of observation, says judge Blackstone, that the convention avoided with great wisdom the wild extremes into which the visionary theories of some zealous republicans would have led them. They held that this misconduct of king James amounted to an *endeavour* to subvert the constitution; and not to an actual subversion, or total dissolution of the government, according to the principles of Mr.

## REVOLUTION.

Locke (Gov. p. 2. c. 19.); which would have reduced the society almost to a state of nature; would have levelled all distinctions of honour, rank, offices, and property; would have annihilated the sovereign power, and in consequence have repealed all positive laws; and would have left the people at liberty to have erected a new system of state upon a new foundation of polity. They therefore very prudently voted it to amount to no more than an abdication of the government, and a consequent vacancy of the throne; by which the government was allowed to subsist, though the executive magistracy was gone, and the kingly office to remain, though king James was no longer king. Thus the constitution was kept entire; which, upon every sound principle of government, must otherwise have fallen to pieces, if so principal and constituent a part as the royal authority had been abolished, or even suspended. Blackitt. Comm. book i, &c. book iv. Hume's Hist. vol. viii.

REVOLUTION, *French*, in its most popular sense, was for several years, after 1789, understood in England to consist of those events which at the outset destroyed the usual order of things, viz. the Parisians' revolt, the capture and destruction of the Bastille, and the submission of the monarch. But these events, singular and important as they were, could not constitute a political revolution: this must have required a change in the government. It is capable, says Mr. (now Sir James) Mackintosh, of three senses. The king's recognition of the rights of the States-general to a share in the legislation, was a change in the actual government of France, where the whole legislative and executive power had, without the shadow of interruption, for nearly two centuries, been enjoyed by the crown; in that sense, the meeting of the States-general was the revolution, and the 5th of May 1789 was its epoch. The union of the three orders in one assembly was a most important change in the forms and spirit of the legislature. This, too, may be called the revolution: and the 23d of June of the same year will be its epoch. This body, thus united, formed the new constitution, which may be called a revolution; because, of all the early political changes, it was the most important, and its epoch was determined by the conclusion of the labours of the National Assembly, on the 30th of September 1791, when the king, Louis XVI., came to the assembly, and having addressed the members, the president proclaimed in his own name, and in the name of the whole body, that "the constituent assembly declares that its power is at an end, and that it will fit no longer." In whatever sense the phrase be taken, the effects have been so momentous, as to claim the attention, and excite the awe of the whole civilized world. In a work of this kind it is impossible to enter into the detail of the various events connected with the French revolution: these must require the pen of the historian, who can devote years to the investigation of facts, and to the development of the motives by which the great actors have been impelled to engage in the several parts connected with their names. The history of the French revolution will afford ample scope and abundant materials for the most interesting narrative of modern times. The New Cyclopædia, embracing every topic connected with human knowledge, cannot devote much space to the history of any country, and still less to a single event connected with an individual state. In the articles FRANCE and LEWIS XVI. we have given a pretty full account of the causes which led to the French revolution, and of the changes which took place previously to the destruction of the Bastille: of the confederacy of the crowned heads against the popular governments, which were established, one after another, on the ruins of the old constitution: of the proscriptions and massacres which were perpetrated in Paris;

and finally, of the decapitation of the king, queen, and the king's sister. We have then traced the progress of Bonaparte, from his consulship to the high dignity of emperor, and noticed the vast and unprecedented power to which he attained over almost the whole continent of Europe, mentioning the kings that had been created by his fiat, and the states that had been subject to his controul, or that stood in awe of his power. This mighty conqueror we followed, in the article France, to his divorcement of Josephine, and marriage with the daughter of the emperor of Germany.

In addition to the above-named articles, to which the reader is referred, we have now to trace the steps of this man from the year 1810, to his expulsion from the throne and empire of France, and shew by what means his obstinacy and ambition caused him to fall from the highest dignities, to which perhaps mortal man ever arrived, to a state of mortification and almost insignificance as the exile to Elba, which may be regarded as the end of the revolution.

For some time the very nature of commerce must have operated as much to the prejudice of his own merchants, as they could do to the prejudice of the merchants of this country; he struck more directly and fatally at the liberty of his subjects by his decrees respecting prisons, domestic servants, and the press.

In the decree respecting prisons, to which we referred in the article FRANCE, it was explicitly declared, that there were many persons, in that country, accused of crimes against the state, whom it was neither safe to liberate nor to bring to trial: for the purpose of keeping these prisoners in safe custody, a number of strong prisons were reared in the heart of the country, in which it was determined they should be confined. There might have been some plea for this mode of conduct during the convulsions of the revolution:—then it might not have been safe nor prudent either to have brought to trial, or to have liberated men whose popular character, or cause, probably would, in the one case, have excited fresh disturbances; and in the other have assured their acquittal, however strong and full the proofs of their guilt might have been. But under the existing order of things it was impossible for the emperor of France to pronounce a stronger libel on his own government, than could be inferred from such a decree. At this time, indeed, he reigned with the most despotic sway over the French, and he seemed resolved to establish, in the heart of Europe, and over a people enlightened by science, a despotism unknown even to the ignorant and enslaved nations of the East. By his decree respecting servants it was evident, that its object was not to be confined to persons in that condition of life, but that it was meant, by putting them under such strict and harsh regulations, to have always at command spies in every family, and thus to establish a more regular and perfect system of espionage. To these acts he issued his mandate, which went to destroy every advantage which attaches to a free press; this, indeed, was not calculated to excite astonishment, for in all despotic countries the liberty of the press has been the object of the tyrant's fear and hatred. At no period did France ever enjoy a free press; but Bonaparte, who seems to have examined and compared all the tyrannical proceedings and measures of despotic governments, both ancient and modern, with a view to improve upon them, and from them to establish a perfect system in France, which should crush the powers of the human mind, had gone beyond all former precedent. By his decrees in the year 1810, of which we are speaking, only a certain number of printers were allowed to carry on their business within the French territories, and these were to be under the most strict and watchful

ral superintendance: of the police; so that nothing could be printed, but what government thought proper to allow and sanction. This has always been the object in despotic countries; but it was obtained with great difficulty, and never with such perfect success as was desired. By diminishing the number of printers, Bonaparte removed the chief difficulty towards destroying the liberty of the press, and succeeded in placing France in a state of mental bondage, perhaps without a parallel in the history of the world.

During this period the emperor of France was employing his troops in Spain, with a view of subjugating that country and Portugal, and uniting the whole peninsula to his already too vast empire. By the exertions chiefly of Great Britain his plans were frustrated. Bonaparte seems, indeed, to have been completely thrown out of his expectations and calculations with respect to the resistance, which he met with in his designs on the independence of Spain; and the protracted and obstinate nature of the contest proved that for a considerable length of time he carried on the war there in a desultory manner, by armies apparently unconnected with each other, and by means not acting in concert and co-operation. About the beginning of 1811, however, a regular plan appears to have been formed by Bonaparte for conducting the war in Spain. The principal feature in this plan was the occupancy of the chief cities in the peninsula: and at the end of the year the French had made considerable progress, they had taken possession of most of the chief towns in Spain; their progress had been slow, attended with great difficulty, interrupted with many reverses, and purchased at heavy expences; still they had made progress, and the emperor, if he could accomplish his objects, never regarded the cost.

In the domestic history of France, the only thing that occurred worthy of notice was the birth of a son to the emperor, who was immediately designated as king of Rome, and in that character received the fervile homage of the legislators of the empire. It was the subject of frequent remark, that after the second marriage of Bonaparte, he for many months seemed to abandon his restless and ambitious projects (with the exception of his attempts on Spain), or that he took much longer time for their execution. During the year 1811, rumours of war between France and Russia frequently arose, and as frequently subsided without any act of hostility on either side. It was not till the spring of 1812 that the war commenced, which was ultimately the cause of the overthrow of the French emperor.

On the 9th of May, 1812, Bonaparte set out from St. Cloud, on the 6th of June he crossed the Vistula, and on the 22d of that month he formally declared war against Russia; two days after this he crossed the Niemen, entered the Russian territories, and immediately commenced hostilities by the capture of Kowno, and on the 28th he entered Wilna, the capital of Russian Poland. In this war he expected considerable assistance from the Poles; he knew their rooted enmity to Russia, and though he had already deceived them, in the expectations which he had led them to form of his erecting Poland again into a kingdom, yet he well knew how to inspire them again with confidence in him; as soon, therefore, as he had entered Poland, his first public act was to proclaim it anew. A diet was immediately assembled, a constitution framed, and the name and form of liberty were restored to the Poles.

Bonaparte had not been long in Russia before he began to experience the disasters of the climate. In the month of July, and when his army was not much farther north

than Wilna, a tremendous tempest arose; torrents of rain fell; thousands of his horses perished, and many pieces of artillery were buried in the mud. His disappointment and chagrin began to manifest themselves; he broke out into invectives on the barbarity of the Russians for laying waste their country in their retreat. Although many severe battles were fought, still the Russians refused to hazard a general engagement. Their perseverance in the plan of retreating astonished the world, and mortified, beyond conception, their enemies, who had no means of preventing this kind of warfare. It was imagined, that for a short time only they would follow up this system, and that their steadiness, passive courage, and patriotism would give way, when they perceived the enemy advancing, notwithstanding their obstinate perseverance, the advanced state of the season, and the desolation of the country. But Russia was animated with one soul, the dread and detestation of the French rose superior to every feeling: considerations of personal interest or comfort, even the sight of their families driven from their homes, and those homes abandoned to the enemy or the flames, had no room in the breast of the Russians: there dwelt only the determination to expel the French, and to obey every command of their sovereign, issued by him or his generals for that purpose. The proclamations of Alexander encouraged the enthusiasm and animated the patient and heroic sufferings of the people; they said, that the emperor was determined to make no peace with Bonaparte, while his legions polluted the soil of Russia: that he would sacrifice all, even Petersburg and Moscow, rather than they should fall into the hands of the enemy. In all the proclamations of Alexander there was no irresolution, no despondence, no expression, that could lead Bonaparte to indulge the hope, that he would propose, or even listen to terms of peace; or his subjects to apprehend, that he would not persevere in what he had begun. New levies were ordered to be raised; the Russian people were invoked by all those powerful feelings and prejudices, which ignorance and superstition create; and when a Russian is told, that what he has to do, or to suffer, is for the sake of his sovereign or his religion, he is made insensible to danger and misery.

Kutusoff continued his retreat, at the head of the main Russian army, till he arrived at Borodino, within a short distance of Moscow. The position here was extremely favourable for defence; though it did not cover the capital, as there were other roads leading to it. On the 7th of September the famous battle of Borodino was fought; it continued from six in the morning till night, when the French, though masters of one part of the field, retreated. The loss on this occasion was immense; not less than 60,000 men are supposed to have fallen on both sides. Both sides claimed the victory; and at Petersburg it was imagined, that Moscow was rendered perfectly secure by the defeat of the enemy. The French, however, retreated, only for the purpose of meeting a strong reinforcement which was advancing, and which actually arrived within a day or two of this tremendous engagement. At the head of these he put himself, and prepared to march by another road for Moscow. As soon as the Russian general was informed that Bonaparte had been reinforced, and that he was manœuvring to get to Moscow by turning the Russians, he resolved to abandon that capital to its fate. Bonaparte therefore advanced to Moscow unmolested, but on his entrance into the city, on the 11th of September, he found its governor and inhabitants animated with the true Russian spirit. They made every resistance in their power to the entrance of the enemy; a great part of the effective population was armed, and as soon as the

## REVOLUTION.

advanced guard of the enemy appeared they attacked them in the streets, and from the houses, impeding their progress, and causing great destruction; and, when it was no longer practicable to prevent the entrance of the enemy, the city was set on fire, and, as it was built principally of wood, the fire spread rapidly in all directions; and before the French could stop the progress of the flames, only a tenth part of it remained unconfumed. It is impossible to describe or even imagine the disappointment, mortification, and wrath of Bonaparte when he beheld Moscow in flames. He had promised his soldiers rest from their fatigues, refreshments, provisions in abundance, and comfortable winter-quarters in it. These were now all at an end: amidst the ruins of Moscow his army would in vain seek for shelter from the inclemencies of the approaching winter, or for a supply of provisions. His indignation soon broke out in conduct at once tyrannical, cruel, and mean: he seized on the men who had set fire to the city, and caused them to be executed.

The situation of the French army in Moscow was now most critical: they were surrounded with armies almost as numerous as themselves, and which were daily increasing. Winter was already making its appearance: the troops had been completely worn down by their long march, and at the end of it, they had met with a reception which neither their leader nor they could have anticipated. The former was certain in his own mind that a complete victory must be the result of the battle of Borodino, and that, as a price of peace, Alexander would find a supply for all their wants, at the expence of his own subjects. Instead of this, the victory was not at all decisive, and Bonaparte advanced with the most cautious steps into Moscow, well knowing, by a fatal experience, that he beheld an enemy in every Russian he met. He soon saw that he could not remain in the ruins of the city till spring should open to him a communication with the southern provinces; and if they retreated, how were they to obtain provisions, and endure a march of 500 miles in a severe and desolating winter, through deep snows, and by the hidden and almost impassable roads of Russia? The Russian generals, true to the cause of their country, and inspired by the animating proclamations of their emperor, took the most active measures to force Bonaparte from Moscow, by cutting off his supplies; and when they had compelled him to retreat, to harass him in every inch of his journey. For this purpose a great number of Cossacks, besides those who had been already employed, were collected, and this was the season of their utility and triumph.

Bonaparte was now sensible of the dreadful error he had committed: unless he actually expected to dictate terms of peace at Moscow, it was the extreme of madness to have proceeded thither at the beginning of a Russian winter; and if he did expect either to dictate terms of peace, or to have his own offers accepted, he must have been ignorant of the determined hatred which all ranks in Russia bore towards him. The apology he offers in his bulletins, for his military career in Russia, is a paltry one; according to him, the Russian winter this year commenced earlier than usual; as if the circumstance of the frost setting in a very few days sooner or later could have saved or destroyed his army! What must be the military prudence of that man, who calculates for the safety of his army, and the success of his measures, on so uncertain a thing as climate! The fact is, Bonaparte, in all his former campaigns, had been indebted for his success to the boldness of his advances into the very heart of the enemy's country; that this boldness did not assume the character, deserve the name, and produce the consequences of rashness, was less owing to his own foresight and circumspection than

to the pusillanimity, treachery, and want of talents of his opponents: without adverting to the different circumstances in which he was placed in Russia, from a difference of climate and national character, he followed his usual plan, thus proving that he was defective in one great feature of a man of abilities, the adaptation of general principles and plans to particular circumstances.

Perceiving that, though he was in the heart of the Russian empire, and amidst the ruins of its ancient capital, no terms of peace were proposed, and that the Russians were gathering round him on all sides, he sent to Kutusoff to propose terms of accommodation, or, at least, an armistice. The Russian commander received the French negotiator in the midst of his generals, and replied to him with the utmost frankness: he told him, that he was not authorized to receive any proposals either for peace, or an armistice; that he would not even send to Alexander nor receive the letter which Bonaparte had sent; and that, with respect to an armistice, the Russian army had no occasion for it, and they were in possession of too many advantages to throw them away by accepting it. The negotiator then began to complain of the savage manner in which the war had been conducted; to this Kutusoff replied in language which ought always to be had in remembrance by invaders: "The French (he said) had introduced the barbarities of which they complained; they had commenced hostilities without reason; had invaded Russia; had inflicted as much misery on its inhabitants as they could; and now, when vengeance and retaliation were at hand, they wished for peace; peace must not even be mentioned till the invaders had retraced their steps, and had again crossed the Vistula; Bonaparte had nothing to do but get out of Moscow how he could, since he came thither without being invited; the Russians, he might depend upon it, would do their duty,—and the duty which they owed their sovereign, their country, their murdered or desolate wives and helpless children, demanded that they should make their invaders suffer as much misery as possible: Bonaparte had proclaimed the campaign at an end at Moscow, but with the Russians it was only beginning." At another time, when the French complained of the excesses of the Cossacks, who had even fired upon their flags of truce, they were told by the Russian general that the Cossacks acted according to orders: "we want," said he, "not to hear of parleys; our object is to fight, not to negotiate; take your measures accordingly." Perceiving that there was no chance of peace, or an armistice, and that the Russians were fully sensible of their own power, and of the reduced and miserable state of the French army, and had formed their plans in such a manner, as to take the utmost advantage of their own good fortune, Bonaparte, after having been upwards of a month in Moscow, prepared for his retreat. A retreat of greater difficulty, and accompanied with more misery, has never been recorded in the annals of history. On the first days of it, the sufferings of the foldiers were feelingly and accurately described in an intercepted letter from the viceroy of Italy. "Three days of suffering have so broken down the spirits of the foldiers, that I look upon them, at the present moment, as scarcely capable of making any effort whatever. Many of them have died of hunger or of cold; many others have gone and surrendered themselves to the enemy." The sufferings of the French, however, were greatly to be increased by hunger, and the severity of the climate.

Early in November the Russian winter set in with more than its accustomed rigour: hitherto the roads had been only deep and heavy, now they became so excessively slippery, that the men could scarcely keep their feet: hitherto the horses, necessary both for the artillery and for the sustenance

of the soldiers, for they were compelled and glad to feed on horse flesh, had proceeded feebly and slowly on, or dropped dead only, a few hundreds every day; but the first day of the frost, nearly 30,000 perished. All possibility of carrying forward their artillery was now at an end; the spirits of the soldiers completely deserted them; they crawled on, exposed to the most dreadful cold, exhausted with fatigue and hunger, emaciated, and almost naked. The road was literally blocked up with the dead and the dying; they had no power to defend themselves against the Cossacks, who constantly hovered round them; they had no inclination to do it: death to them would have been a blessing: at the sight of the Cossacks they hoped their miseries would soon be terminated: but their enemies were not so merciful as to put them to death; piercing them with wounds, stripping off the little covering they had, they left them on the snow, there bleeding and naked, exposed to the rigours of a Russian winter. Whenever the French entered any village where there was the least chance of repose or food, they exerted their little remaining strength, and crawled on their hands and feet to seek it. Frequently, just as they had stretched out their hands to seize a little food, or reached the threshold of a wretched hut, under which they looked for shelter from the weather, perhaps for a few minutes sleep, the remnant of their strength failed them, and they expired.

With what feelings and sentiments did they now regard Bonaparte! No longer the adored general, who seemed to have chained victory to his car, to be more than mortal, and to be destined to render all Europe subservient to the interests and glory of France; they cursed him as the author of all the misery under which they were writhing; on his person they willingly would have inflicted vengeance; but sensible of their indignation, he had gathered round his person his principal officers, mounted on almost the only horses that remained. For some time he rode in a coach, till the dreadful voice of his soldiers commanded him to walk as they did, and to share their fatigue; he still, however, defended himself from the inclemency of the weather with a cloak; "off with your cloak" was another stern command, that he durst not disobey. Such was the situation, — such the feelings of the French army during their dreadful retreat, in which every thing that could accumulate or sharpen misery befel them. It fearfully needed the presence of an enemy to complete the work of destruction; the climate of Russia, aided by hunger, was amply sufficient.

In fact, the French soldiers could no longer be said to compose an army; they were straggling in all directions, anxious indeed to avoid the Cossacks, since from them they experienced only an aggravation of their misery, but not unwilling to fall in with the regular Russian troops, in the hope of being taken prisoners, or falling in battle. Their ignorance of the country, and the state of the roads, were such, that the different divisions of the French army could not support one another; and frequently when expecting to fall in with the main body, they encountered the enemy and were taken prisoners. On the 10th of November, before they reached Smolensk, general Augereau, with 2000 men and 60 officers, surrendered themselves; this was the first instance, during the present war, of a whole corps laying down their arms. It is computed that in three days time, prior to that date, they lost 20,000 men, besides nearly 20,000 more that fell in the previous engagements; nearly 300 pieces of cannon had also either fallen into the hands of the Russians, or had been spiked and buried by the French. But these losses, enormous as they were, were only preludes to greater ones.

It is extremely difficult to form an estimate of the loss of the French in this dreadful campaign. The Russian official accounts state that they took upwards of 150,000 men; and it was calculated that the number of killed, and of those who perished by hunger, fatigue, and cold, amounted nearly to 100,000; so that reckoning that the French army when it crossed the Niemen, and began the campaign, amounted to 300,000 men, scarcely more than 50,000 escaped out of Russia; and of those, a large proportion must have suffered so dreadfully as to be absolutely unfit for future service. Such is a bare outline of this disastrous campaign, the consequences of which have proved so important to the liberties of Europe. In it we have seen the first general of his age, at the head of one of the finest armies that was ever raised, and which placed in him the most unbounded confidence, flying, beaten, disgraced, bereft of the greatest part of his troops, and the object of detestation to the remainder. This is an event which, taken under all its circumstances, cannot be paralleled in history. No war, ancient or modern, exhibits such destruction and misery; more, no doubt, have fallen in the field, in the course of a campaign; but no army ever perished with such lingering and varied misery. The cause of the failure of the Russian campaign under the auspices of that same general, who had on almost all great occasions been successful before, is the business of the historian to investigate, and will long afford matter for speculation and curious discussion. "It has scarcely ever fallen to the lot of the historian or annalist," says the intelligent writer in the New Annual Register, "to narrate such disasters; and when we consider that these disasters befel a man who, from a low station in society, had raised himself to the very summit of power, to an extent of dominion and influence never before witnessed in Europe; that this man, for the purpose of a mad, bloody, and desperate ambition, had trampled on all the laws and usages of justice and civilized society; and that he considered himself, and called upon the world to acknowledge and fear him, as absolutely beyond the reach of fate, as something more than mortal; when we moreover reflect on the peculiar interest which this country felt in all that befel him, since against this country was his most implacable and deadly hatred directed; and from that hatred, his ruin indirectly originated; when we take all these things into our account, we must acknowledge that we cannot examine too closely, or scrutinize too minutely, the causes of his failure in the Russian campaign."

It appears, then, that these causes may be classed under two general heads, *viz.* those which proceeded from the nature of the country which he invaded, and the characteristic qualities of its inhabitants; and those which originated from the peculiar character of the invader.

In the first place, the constitution of the Russian army, and the character of the Russian soldiers, contributed in no small degree to the fate of Bonaparte. The Russians, from their infancy, are most devoutly attached to their emperor, and to their nobility. Philosophers may ridicule the idea, or disbelieve the assertion, that the common people of Russia are attached to those who act towards them, in too many instances, as tyrants. But history is conversant with facts, not with theories and speculations; and the fact is, that the Russian common people, even before they enter the army, are most devoutly attached to their emperor and nobility. This attachment becomes still more strong and influencing when they enter the army: — they then regard themselves, in a more special manner, as entirely at the service of their sovereign; and look upon it as the highest honour which can befall them, to suffer any privation or misery, or even death itself, at his command, and for his sake.

fake. Military discipline, with the troops of most other nations, is a habit acquired late in life, irksome and abhorrent to former habits, and broken through whenever it can be done with safety. But it is far otherwise with the Russian soldier: he knows no habits; he has no feeling or sentiments incompatible with the strictest military discipline: on the contrary, all his other habits, feelings, and sentiments, work to the accomplishment of the same end: all serve and contribute to render him an excellent soldier, so far as strictness of discipline is concerned. Knowing no disgrace so great as disobedience to the orders of his officers, and especially to the commands or even wishes of his sovereign, he never stirs from his post till he is expressly directed so to do: the idea of flight never enters his mind. But his steadiness is not merely passive; endowed with great bodily strength, and with a robustness of constitution superior to every fatigue or privation, he wearies out his more skilful and experienced opponent, by whom he may be outmanœuvred or slain, but cannot be forced to fly.

Hence Bonaparte never met with more obstinate resistance than he did from the Russians at the battle of Eylau: his troops were weary with slaughter, but still they could not defeat the Russians; and had the French emperor been a man who could be taught mortifying or disagreeable truths by experience, after his first campaign against the Russians, on the borders of their own country, he never would have attempted to conquer them, in the very heart of their empire, and in the midst of a Russian winter.

In the second place, the character of the Russian generals contributed not a little to the defeat of Bonaparte: his avowed object in the invasion of Russia, was to compel the emperor Alexander to adhere to the continental system, that was, to forbid all trade between Russia and England; but this would have been the ruin of the Russian nobility, whose incomes were almost exclusively derived from this commerce. Bonaparte, therefore, was making war upon them, and they must have regarded his invasion as peculiarly directed against them. This feeling would contribute to render them faithful and steady to the cause of their country, and at the same time stimulate them to put forth all their activity and talents in the contest. Besides, the Russian nobility partake with the common people in that physical attachment to the soil and institutions of their country, which excites their hatred most strongly against all invaders. Hence they were above the influence of Bonaparte's promises and bribes.

In the third place, the plan of the campaign which the Russian government had laid down, contributed very essentially to the overthrow of Bonaparte's hopes and projects. This plan was, on every occasion, where they could oppose Bonaparte, there to oppose him, but never in such a manner as might bring on a general action, or an action that could be decisive against themselves. Thus, the farther he advanced the weaker he became; and after every engagement, though he apparently succeeded in driving back the enemy, the real state of his affairs was rendered worse: he was led further from his resources, deeper into the heart of a country utterly incapable of supporting a large army, and more completely surrounded by the Russians.

In the fourth place, the character of the Russian peasantry contributed much to the defeat of Bonaparte: these could not be seduced from their allegiance; they uniformly, and to a man, refused to hold any communication with the enemy: while Moscow was in the hands of the French, they brought no goods in for sale: they regarded it as a polluted city, and would have shuddered to have entered it.

To these causes must be added the firmness of Alexander; and the nature and climate of the country.

The next class of causes which contributed to Bonaparte's discomfiture and ultimate ruin, must be sought for in his own peculiar character, in which the most predominant and influential is his obstinacy. Accustomed to see all his plans succeed, all his predictions, however extravagant, verified, he could ill-brook disappointment: he could not even suffer himself to admit that he had acted an imprudent and rash part, and preferred perseverance in error, to the acknowledgment and rectification of it. His obstinacy operated in giving rise to the invasion of Russia, as well as influencing his conduct during that invasion. He probably pushed forward into Russia notwithstanding the losses which he sustained, and afterwards continued in Moscow till winter had rendered his retreat almost impossible, under expectation, or at least the hope, that Alexander would be induced to propose terms of conciliation. This certainly influenced his conduct; "but," says a good writer, "whoever has studied the character of obstinate people, must be convinced that at last, when their obstinacy is got to its greatest height, they persevere in the course which must infallibly conduct to ruin, without even the most groundless hope of extricating themselves. The impulse in this state of mental disorder, for so it may be denominated, is blind, and almost mechanical. So it probably was with Bonaparte, when he determined to remain so long at Moscow."

How different were the affairs of this man at the commencement of 1812, from what they were at the same period in the following year. At the former every thing was prosperous, except perhaps the war in the peninsula; and that, it was generally believed, he could, at any time, turn in his favour by sending a larger army there. Russia, though uneasy under the operation of the hard terms to which she submitted at the peace of Tilsit, would scarcely have ventured to commence a new war; while the subserviency of Prussia to his will, his absolute command of her fortresses which are on the confines of Russia, and his alliance and family connexion with Austria, seemed to promise him the easy conquest of Russia whenever he should think proper to attack her. At the latter period he no longer appeared as the invincible conqueror, but as the fallen general, who had fled to his capital with unexampled celerity, to avoid the indignation of the fragments of that army which had been sacrificed to the madness of his ambition. He who had always detailed victories the most splendid, who had, in direct language, held himself out as superior to all the casualties of war, was now obliged, in his own bulletins, to confess that his army was broken, and it was returning towards France defeated and harassed by the Tartars of Asia.

Thus changed in power, in feelings, and in prospects, the Parisians saw their emperor at the beginning of the year 1813, and they, as well as Europe in general, were extremely anxious for the meeting of the legislative body, in order that they might be able to develop his future plans. At this meeting, on the 14th of February, he declared it to be his determination still to carry on the war, and to sacrifice nothing for the sake of obtaining peace: "The French dynasty," says he, "reigns, and will reign, in Spain. I am satisfied with all my allies; I will abandon none of them; I will maintain the integrity of their states; the Russians shall return to their frightful climate. I desire peace, but I will never make any but an honourable peace, and one conformable to the interests and grandeur of my empire." The whole tone of his address was warlike, and he immediately set on foot a new conscription, which, by means of his gens d'armes,

d'armes, he readily carried into effect, at least to a certain point. By means of uncommon exertion and activity, joined to the most tyrannical despotism, he succeeded, by the beginning of April, in collecting a large force on the banks of the Elbe, though that force was of a very different description from the veteran army which he had lost in Russia. His cavalry and artillery were particularly inferior; and it was on these two branches, especially the artillery, that the French used to depend for their victories; it is even said that, in consequence of his having lost upwards of 1000 pieces of cannon in Russia, he was under the necessity of supplying his army, in a great measure, with cannon from the ships at Antwerp, which were, of course, of a description by no means suited for military purposes.

Before Bonaparte left Paris, to take the command of his army, he judged it expedient to settle the form of a provisional government during his absence: he had so narrowly escaped destruction in his Russian campaign, at a time when he had taken no measures respecting the government of France while the king of Rome was a minor, that he resolved to guard against all accidents for the future. Accordingly his empress was regularly declared regent during his absence; and the king of Rome was nominated, in a more solemn manner than heretofore, his successor. It is probable that the appointment of the empress as regent had other objects in view; Bonaparte knew well the temper and disposition of the Parisians; he knew that the best mode of drawing off their thoughts and speculations from the disasters that had occurred, or might occur, was by keeping up the splendour, bustle, and pageantry, of a court; and this could be done with the best effect by investing his empress with the name and dignity of regent. Having thus taken what he conceived to be all due precautions, and sent on before him immense bodies of troops, he closed the session of the legislative body in a speech full of his usual confidence and haughtiness, in which he led them and the French nation to expect, that on the banks of the Elbe he should regain all those laurels which he had lost amidst the snows of Russia.

Having thus detailed the preparations which Bonaparte made for the commencement of what has been denominated the German campaign, we must notice briefly the preparations of those powers who were to oppose him. Alexander, at the head of his army, advanced with great rapidity into the north of Germany. As soon as he crossed his own boundaries into those of Prussia, he ordered a declaration to be issued, explanatory of his motives and views. The Russian emperor was every where hailed as a deliverer, and upon his entrance into Berlin he was received with the utmost enthusiasm by all ranks of the people, and in the end Prussia became a noble ally to the northern potentate. She was indeed declined to act a conspicuous part in avenging her own wrongs and those of Germany. Her armies were put on the best footing. Blucher, who had already immortalized himself by his conduct, had a leading and extensive command; and it seems to have been the wise policy of the continental sovereigns, in this last struggle for their independence, to select those generals against whom Bonaparte had displayed the greatest rancour; they thus secured themselves from treachery, while they called forth all the talents of their commanders. Besides the regular army of Prussia, the landwehr or militia were called out; all were anxious to be enrolled to co-operate in the deliverance and defence of their country.

In the mean time the Russian army continued to advance, and having liberated great part of Prussia, directed their efforts towards the emancipation of Saxony. Count Wittgenstein, who commanded the Russian army, addressed to the

Saxons a most noble and inspiring proclamation, which, though it probably made a deep impression, did not, at the time, produce the consequences which the Russian general anticipated. The king of Saxony was with the French, and no small part of their country was occupied by those people, circumstances which naturally prevented many from joining the allies whose wishes were cordially with them; when, however, an opportunity did occur, it will be seen that the Saxons proved themselves worthy of the name of Germans, and of their ancestors. A hope was now excited that Bernadotte, the crown prince of Sweden, and his numerous army, would be brought to act in favour of the allies; this expectation was considerably strengthened by treaties which were concluded between the courts of Sweden, Russia, and Great Britain. By these treaties, the army under the crown prince was immediately to be employed in the common cause, and in return for his accession of force, Great Britain, besides granting a subsidy to Sweden, agreed to give up to her the island of Guadaloupe, and to guarantee the kingdom of Norway when it should be conquered from the Danes.

Thus it was known that early in the year 1813, Great Britain, Russia, Prussia, and Sweden, were decidedly against France. Hostilities commenced, and in many parts the French were decidedly victorious; Hamburgh, and many other places in the north of Germany, fell into their hands. The first great battle in which Bonaparte was himself engaged, was at Lutzen, on the 1st of May; the Prussians, having partially succeeded in breaking into the squares of the enemy, committed great carnage, and the conflict on all sides was most desperate and sanguinary. For a considerable time the allies were the assailants, but towards evening, Bonaparte called in that division of his army which was near Leipzig, and collecting all his reserves, made a most furious attack, for which the allies were not prepared; night however put an end to the combat. The allies remained masters of the field that evening, but judged it prudent, early on the next day, to commence a retreat, in consequence of which Bonaparte claimed the victory in the battle of Lutzen. But it was not such a victory as he used formerly to boast of; and on the 21st of May another bloody battle was fought at Bautzen, which was still in favour of the French, and the allies again found it expedient to retreat. The loss of the enemy in this oblique battle was very severe; though Bonaparte gained ground by it, he gained it at such an expence of men, and with such a conviction of the bravery and skill of the allies, that he must have been very unwilling to have obtained many such victories. But the most alarming circumstance which occurred during the battle of Bautzen, was the desertion of a whole battalion of Wurtembergers, as well as a body of Saxon troops, which must have convinced Bonaparte how little dependence he could place on the German troops. The allies continued their retreat, and on the 24th of May their head quarters were within 18 leagues of Berlin. On the 4th of June, through the mediation of the emperor of Austria, an armistice was agreed on, which was to continue till the 20th of July. It was a matter of great difficulty to determine on which side the advantage of this armistice lay; both parties were probably desirous of it, and as the emperor of Austria pressed it most earnestly, each party readily agreed to it, in the hope of gaining his assistance, or avoiding his hostility. It was, however, extremely unpopular throughout Germany, and especially in the Prussian states; so much so, that the king deemed it necessary to issue a proclamation, in which he declared that the armistice had not been sought for by the allied powers, and that they would

only use it to re-inforce their armies, and attack the common enemy, at its expiration, with more vigour. Bonaparte, on his own part, complained that the terms of the armistice were not faithfully kept by the allies; this complaint, which was well founded, arose from a circumstance which augured fatally for his future success; for the landwehr of Prussia, and even all the inhabitants who could procure any kind of arms, notwithstanding the suspension of hostilities, were continually attacking and harassing the French, and in many cases they captured their supplies of stores and provisions, and rendered precarious and difficult their communication with France.

It was soon evident that the armistice would not lead to peace, each party was exerting itself to the utmost to recruit and re-inforce their army. The emperor Alexander ordered fresh troops to be brought across the Vistula, and in a short time the re-inforcements that joined the allied army from Russia alone, amounted to 75,000 men. The king of Prussia contributed as much to the common cause as the exhausted state of his country, and of its finances, would allow. Bonaparte was equally active; opposite to the main army of the allies he had collected nearly 130,000 men.

The armistice was prolonged till the middle of August, during which a congress was held at Prague, at which little or nothing was done, or perhaps even attempted. The mediation of the emperor of Austria was of no avail; the terms which he proposed as just and equitable to all parties, were peremptorily rejected by Bonaparte. No alternative, therefore, he said, remained for him to adopt, but to unite his forces with those of the emperor of Russia and the king of Prussia. Still, however, he, as well as they, were going to fight, not for the purposes of ambition or conquest, but solely for the attainment of a just, honourable, and lasting peace. As soon as this could be brought about, they would most cheerfully lay down their arms; but till it was brought about, they would continue united in hostilities, and exert themselves to the utmost.

Russia, Austria, Prussia, and Sweden, were now to try their strength against France; the jealousies and selfishness of the allied sovereigns, which had rendered former coalitions of no value, were absorbed in the deep and awful conviction that now they were fighting for their own existence; besides, in the former contests, they were averse from, or indifferent to, the cause of their sovereign; now they were cordial and zealous in their co-operation. The allied powers also very wisely made use of other weapons than those of warfare; the most eloquent and popular writers in Germany were employed to rouse the people, to hold out Bonaparte as no longer formidable; as having been conquered; but still as the implacable enemy of the happiness and peace of Germany, as the common destroyer of the liberty of the sovereign and the peasant.

Besides the crown prince of Sweden, another Frenchman entered into the lists against Bonaparte, *viz.* general Moreau, who, after he had been liberated by him, had gone over to America, where, in peace, quiet, and retirement, he had spent some years of his life. It is not known by what particular motives he was induced to enter again into public service; but it appears that the emperor Alexander, as soon as he found that war with Bonaparte was inevitable, sent over a confidential person to America, with whom general Moreau returned to Europe. He joined the allied army soon after the congress at the Prague was dissolved.

On the 17th of August hostilities recommenced, and a most severe battle was, a few days after, fought at Dresden, in which, after a terrible slaughter on both sides, the French succeeded in repulsing the allied armies, but the most dis-

astrous event in the course of this battle was, the death of Moreau, who had both his legs shot off by a cannon ball.

Bonaparte represented the battle of Dresden as most decidedly favourable to him, and he probably considered the loss and discomfiture of the allies as much more serious than they really were, as in order to intercept their retreat into Bohemia, he dispatched Vandamme, one of his generals, with a force which it would have been madness to have sent against them, had he not believed their army to have been not only much reduced in numbers, but retreating in great disorder. In the attack, Vandamme, and six other generals, were taken prisoners, besides 10,000 men, 60 pieces of artillery, and 6 standards.

In Silesia the campaign opened on the 18th of August, the allies in this quarter moving on towards Dresden; they first attacked and defeated a corps under marshal Ney, which induced Bonaparte to set out to re-inforce his general; the French having now greatly the superiority, general Blucher retreated, and took up a strong position behind the Katzbach. The plan of the allies being to distract and divide Bonaparte's forces, they fell farther back, while the grand army from Bohemia, as we have seen, marched on to Dresden, and drew off Bonaparte to that quarter. On the 25th and 26th the French advanced against Blucher, but on the latter of those days the Prussian general attacked them. The battle was fought near the Katzbach, and from that takes its name; in it Blucher and the Prussians proved their determination to avenge the disgrace which their country had so long suffered by having been under the tyranny of France. They fought with the most unparalleled bravery, and gained a complete victory. Among the fruits of their spoil were 18,000 prisoners, 103 pieces of cannon, and 280 ammunition waggons. In another quarter the crown prince was likewise victorious over the French; and in a second battle, *viz.* that of Juterbock, it was calculated that the vanquished French had lost from 16 to 18,000 men, more than 50 pieces of cannon, and 400 ammunition waggons.

After these defeats the situation of Bonaparte became more critical, yet he still remained at Dresden, and continued there till the 7th of October, when he quitted it, taking with him the royal family of Saxony. Hitherto the allies of Bonaparte had remained more faithful to him than might have been expected, but about this period the king of Bavaria deserted him, and concluded a treaty of alliance and concert with Austria, by which 35,000 Bavarian troops were immediately to co-operate with those of Austria.

On the 14th of October Bonaparte collected his whole force in and round Leipzig, and on the 18th the famous battle of Leipzig was fought, in the course of which two Saxon battalions, and two Westphalian regiments of hussars, quitted the ranks of the enemy and joined the allies; the artillery which they brought over with them, they immediately turned against the French, and the crown prince headed the men in a charge against their former oppressors. In the battle of this day the French lost at least 50,000 men in killed, wounded, and prisoners, besides 65 pieces of artillery. Bonaparte now left Leipzig, and in two hours afterwards the allied armies entered that town.

The retreat of Bonaparte from Leipzig with the wreck of his army, to the amount of 80,000 men, was scarcely surpassed in disorder and misery by his retreat from Moscow. As soon as he reached the Rhine he left his army, hastened to Paris, and on his arrival, another conscription of 300,000 men was ordered, but France was now too much exhausted to answer the demand; the Russian and German campaigns had almost entirely stripped her of the efficient military population; besides, there was wanting that enthusiasm which had,

twenty years before, been characteristic of the country, fo that it was almost deaf to this new demand.

In the mean time the mighty edifice which Bonaparte had erected out of the ruins of the independence and liberties of the continent, and which had been cemented by the blood of hundreds of thousands, was falling to pieces; the victory of Leipsic, by freeing the minds of the princes of Germany from all apprehensions of his power, proved how eager they were to resume their legitimate character and authority. Wurtemberg deserted him, and made her peace with the allies; and the confederation of the Rhine was dissolved; so that, to use his own words, no sovereigns remained attached to him except the king of Denmark and the king of Naples.

Holland, which had long groaned under French tyranny, early in the month of November broke her shackles, dismissed the constituted authorities, established a provisional form of government, and by the assistance of Great Britain she was at length enabled to hold up her head as a free and independent nation, recalling her hereditary prince, and investing him with new powers, and higher titles than the members of the house of Orange had formerly exercised and claimed. Rather before this period the allied troops, under the command of the crown prince, had entered Hanover, which they liberated from French thraldom, much to the satisfaction of the inhabitants, and by the end of November almost all the strong places between the Elbe and the Rhine were in possession of the allies, and such as were not, were closely invested. On the 1st of December they issued their famous proclamation, which, from its justice and moderation, probably did them as much, or more, service, than any of their victories. "The allied powers," say they, "do not make war upon France, but against that preponderance which, to the misfortune of Europe and of France, the emperor Napoleon has too long exercised beyond the limits of his empire.

"Victory has conducted the allied armies to the banks of the Rhine. The first use which their imperial and royal majesties have made of victory, has been to offer peace to his majesty the emperor of the French. An attitude strengthened by the accession of all the sovereigns and princes of Germany has had no influence on the conditions of that peace. These conditions are founded on the independence of the French empire, as well as on the independence of the other states of Europe. The views of the powers are just in their object, generous and liberal in their application, giving security to all, honourable to each.

"The allied sovereigns desire that France may be great, powerful, and happy; because the French power, in a state of greatness and strength, is one of the foundations of the social edifice of Europe. They wish that France may be happy, that French commerce may revive, that the arts (those blessings of peace) may again flourish, because a great people can only be tranquil in proportion as it is happy. The allied powers confirm to the French empire an extent of territory which France, under her kings, never knew; because a valiant nation does not fall from its rank, by having in its turn experienced reverses in an obstinate and sanguinary contest, in which it has fought with its accustomed bravery."

Immediately after the issuing of this declaration, the allies having completed their arrangements, crossed the Rhine for the purpose of invading France; as, however, the strong fortresses near Mentz rendered the passage in this place rather difficult, they preferred passing through Switzerland, by the inhabitants of which country they were hailed as friends, and afforded every assistance.

The allied army entered Switzerland on the 20th of December, penetrated to Zurich and Berne, and crossed the Rhine at Basle without firing a shot, and before the end of the year detachments of the allies made their way to Langres, in Champagne, which was about 100 miles within the old French frontier. The year 1814 opened with an invasion of France, not only by the allies in the east and north, but on the south by lord Wellington, while the Austrian forces in Italy, aided by the naval exertions of Great Britain, and by detachments from our garrisons in the Mediterranean, completely kept the viceroy in check. Every event tended to shew that Bonaparte's power was tottering, and he must have been convinced that he had only one thing to depend on, *viz.* his own personal prowess. He accordingly left Paris on the 25th of January to take command of the armies, and on the 1st of February a great battle was fought between him and marshal Blucher, which was decided in favour of the allies, and the retreat of Napoleon from his positions about Brienne, with the loss of 4000 prisoners, was the consequence of his defeat.

On the 7th of February the position and town of Troyes was taken possession of by the allies; this town was thought to be of great importance to their cause, on account of its resources, its population, and of the number of roads leading to it from different parts of France. At this period negotiations were carrying on at Chatillon-sur Seine for the purpose of effecting a peace, during which the allies had gained several conquests over the French armies. Bonaparte had been beaten in several engagements with Blucher and prince Schwartzburg, whose armies, at the close of February, were at Troyes and Chalons, while he himself was at Rheims. On the 19th of March the negotiations were to terminate, and on that day Napoleon refused the terms that were offered him, though by those terms he would have continued at the head of the French, with dominions as extensive and powerful as had ever been enjoyed by any of the former monarchs.

On the day that the conferences at Chatillon were terminated, the French army moved upon Arcis, behind which the corps commanded by field marshal count Wrede was posted.

The allies, under Schwartzburg, concentrated on the Aube, near Pougy and Arcis, and a general attack was made by the allies on the 20th, in which the enemy was defeated at all points, with great loss, and Arcis was taken.

At this juncture, Napoleon formed the desperate and extraordinary plan of passing between the two armies of the allies, and of striking at their communications with the Rhine, intending at the same time to liberate the garrison of Metz. For this purpose he moved by Chalons on Vitry and St. Dizier, his head-quarters being, on the 22d, at Obcomte, between the two latter places. This bold and characteristic resolution was formed in the expectation that it would alarm the allies so much for their own safety, as not only to draw them away from Paris, but actually entangle them in the very difficulties with the prospect of which he endeavoured to terrify them;—this movement was fortunately defeated by their resolution of marching upon Paris, a resolution which was—considering the time and circumstances in which it was taken—one of the grandest that ever entered into the mind of man, and does the highest honour to the names of the emperor Alexander and prince Schwartzburg;—to which of those great men the idea suggested itself, perhaps they themselves are not conscious; but it is certain they both eagerly adopted it, and must equally share in the glory of that great enterprise in which they risked themselves and their armies for the deliverance of mankind.

## REVOLUTION.

For two days after this determination and change of march, Bonaparte was employed, as he hoped, in anticipating the allies, and in preparing the springs in which his victims were to be caught; but no enemy came—no intelligence arrived: from Paris he heard nothing—from the rest of France little; and a hostile army of 200,000 men must be, he knew, at no great distance from him, but he could not guess where. Over Winzingerode, who was in his vicinity, near St. Dizier, with a small force, he obtained some, and claimed greater advantages; but these successes left him as much in the dark as ever.

He was convinced that this corps was but the advanced guard of the Russians; and when one of his generals reported it was not so, and that the main body of the allies had suspended their retreat, he himself thought the news almost too good to be believed, and calculated that the time thus lost would enable him to perfect his plans for their destruction.

In these circumstances, it was Napoleon who thought his enemies undone; and far from considering them as having resumed the offensive, he saw in their movement of concentration only a measure of retreat. He announced it triumphantly to the empress in letters written with his own hand: these letters were intercepted by the allies. They were then certain of having deceived him, and they urged with great precipitation their movement against the capital.

Of the march upon Paris either he never thought, or his arrogance hastily rejected the idea; but at last, after a loss of three days, he felt that it became absolutely necessary to ascertain the enemy's position, and he accordingly hastened by forced marches through Bar-sur-Aube towards Troyes. A junction was, however, formed by prince Schwartzburg and marshal Blucher; and the whole allied force marched upon Paris, with a rapidity that insured its success. The defences which had been raised in the neighbourhood of that city were attacked late in the day of the 30th March, and the enemy, under the command of Marmont, made a most determined resistance; but the allies were almost every where successful.

At the moment of these decisive advantages, a flag of truce was sent from Marmont, intimating a desire to receive any propositions that it might have been intended to make to him by a flag of truce, which had previously been refused admittance. An armistice was also proposed by him for two hours; to obtain which, he consented to abandon every position he occupied without the barriers of Paris.

On the 31st in the morning, the allies entered Paris. In the evening, Caulincourt came from Bonaparte to the emperor of Russia, offering to accede to the terms of peace which the allies had offered at Chatillon. The emperor gave no other answer, than that the time was past for treating with Bonaparte as sovereign of France.

Immediately, by the desire of the emperor of Russia, the senate met, and chose a provisional government, consisting of Talleyrand and four other members. At their second sitting, they declared that Bonaparte had forfeited his right to the empire, and that his dynasty was at an end. They also resolved, that the senate and legislative bodies should form fundamental parts of the new constitution.

On the 1st of April the provisional government installed itself, and of this Bonaparte seems to have been aware; and on the 2d he collected at Corbeil, Fontainebleau, and the neighbourhood, at least 20,000 men, whom he reviewed and thus addressed: "The enemy is in Paris. I do not wish to speak of the inhabitants of that city, but a horde of emigrants, whom I had recalled, restored, and laden

with personal favours, have offered their services to the emperor of Russia, and have hoisted the white cockade. The tri-coloured cockade we won in our revolution; we have ennobled it in our empire. It has shared too many triumphs with us ever to be abandoned. If Paris is to be retaken at the point of the bayonet, I will march at your head. May I reckon upon you? Am I right? Will you ever abandon this national cockade?" "Never, never; vive l'empereur! vive Napoleon! à Paris!" was the answer of the whole line of troops.

The marshals present at this scene were far from partaking or encouraging this enthusiasm: they that same night assembled in the palace, and when admitted to Napoleon's presence, with many references to their former services, and professions of duty and affection, acquainted him that all was lost; that at most he could collect but 56,000 men, and that for them he had not two days provisions; but the only means of saving any thing from this great shipwreck, was to abdicate in favour of the king of Rome.

Bonaparte, for the first time in his existence, heard a remonstrance in silence, and ultimately assented to the proposal. On the 3d, marshal Ney put into his hands the Paris journals, in which the *déchéance*, pronounced by the senate the day before, was published; and, in the name of his brethren, on the public parade, gave him that advice so terrible to the ear of a tyrant, "Sire, il faut abdiquer; c'est le vœu de la France et de l'armée." Napoleon, thunderstruck, retired into the palace. On the 4th he signed his own abdication, and addressed an order of the day to his army, in which, after contrasting forcibly and justly the former servility and present tergiversation of the senate, he intimates, that if he is the only obstacle to peace, he is ready to make the last sacrifice for France; and that he has sent Ney, Caulincourt, and Macdonald to Paris, "pour entamer des négociations." These negotiations, which had for their object the continuance of Bonaparte's power under the cloak of a regency, to be administered by his wife, in her own name, or that of her son, happily failed. Others then ensued, in which the discussions were not questions of policy, power, or government, but of pounds, shillings, and pence; and on the 11th of April was signed the famous treaty, by which Bonaparte abandoned for himself and his family the thrones of half the world, and stipulated only for the empty titles of his better days, a retreat in the obscurest corner of his late dominions, and a pension of 2,000,000 of livres *per annum* from the civil list of Lewis XVIII.; and, finally, on the 12th he signed the formal instrument of his abdication on the part of himself and his dynasty.

Such was the termination of this disastrous revolution; and in a very few weeks after the deposition of Bonaparte, Lewis XVIII. returned, and took a quiet possession of the throne of his fathers. Of the stability of the new government we presume to offer no conjectures. Of the character of the present sovereign much might be said in applause; of the new constitution, at present, we know but little: and into what it may ultimately settle it is difficult to speak. Many recent occurrences in different parts of Europe have mortified the friends to human happiness; the society of Jesuits, always inimical to the interests of mankind, has been re-established. The Inquisition, which Bonaparte abolished, and which it was imagined could, in this enlightened age, never more rear its horrid head, has been revived in Spain, to the everlasting disgrace of the prince who ordered its establishment, and to the people who permitted it. When we read the decree, that "the

tribunal of the Inquisition is abolished, as derogatory to the sovereign power, and to civil authority," we did anticipate a new era, even for Spain, and are mortified, beyond the power of language to describe, to find that several of the best and most virtuous inhabitants of that country are now suffering under a tribunal which cursed the world for so many centuries, which, for the boldness and wickedness of the original conception, the immense extent of its power, the audacity of its attempts, the greatness of its success, and the length of its domination, finds no parallel in the records of the world.

We might, as a conclusion to this article, take some notice of the principal actors and sufferers in the revolution which we have been contemplating, but we are afraid of transgressing the allowed limits. Besides, in our alphabetical arrangement, we have already noticed several of the most distinguished of these persons; see particularly the articles BAILLY, CONDORCET, MARAT, MIRABEAU, LEWIS XVI., MALESHERBES, and NECKAR, and to some others, according to the plan of our work, distinct articles will hereafter be given. (See ROLAND-TURGOT, ROBESPIERRE, VERGNAUD, &c.) Of Danton, who took a very active part in some of the bloodiest scenes in Paris, and who fell a victim to the axe which he had sharpened for others, we may observe, that he was educated to the law, and in the progress of the revolution was successively the associate of Mirabeau, Marat, and Robespierre. He organized some of the chief tumults and massacres in the city, particularly that of the 10th of August. After the fall of royalty, he obtained an appointment of administrator of justice, a station in which money poured on him from all sides, and which was speedily distributed by him to procure adherents and reward atrocities. He was deeply involved in the horrid massacres of September, and, when subsequently called to account for the distribution of the money charged for secret service, he declared, that "in a revolution there could be no reckoning in detail." It was Danton who prevented the national assembly from leaving Paris on the approach of the Prussians. He was brought to the guillotine by Robespierre, who was his rival, but his inferior in every thing but cunning and hypocrisy. For this article, we refer, as authorities, chiefly to the volumes of the New Annual Register.

REVOLUTION of *America*. See AMERICA, and UNITED STATES.

REVOLUTION in *Poland*. See POLAND.

REVOLUTION, in *Geometry*. The motion of any figure quite round a fixed line, as an axis, is called the revolution of that figure; and the figure so moving is said to revolve.

Thus, a right-angled triangle, revolving round one of its legs, as an axis, generates, by that revolution, a *cone*; which see.

REVOLUTION, in *Astronomy*, denotes the period of a star, planet, comet, or other phenomenon; or its course from any point of its orbit, till it return to the same.

The planets have a twofold revolution. The one about their own axis, usually called their *diurnal* rotation, which constitutes what we call their *day*.

The other about the sun, called their *annual* revolution or *period*, constituting their year. See *Motion of the PLANETS*.

REVOLUTUM FOLIUM, in *Botany*. See LEAF.

REUS, in *Geography*, a town of Spain, in Catalonia, where several merchants at Barcelona have agents for the purchase of wine, brandy, and fruit, with which the country abounds.

REUSS, a river that rises from a lake in Mount St.

Gothard, crosses the canton of Uri, passes through the lake of the Four Cantons to Lucerne, and then taking a northerly course, runs into the Rhine, two miles N. of Klingnau, in the county of Baden.

REUSSEN, a princely county of Saxony, divided into several branches, which take their names from the towns which they possess, all situated in the Vogtland.

REUSSIN, or REDZEN, a town of the duchy of Warsaw; 40 miles S.S.W. of Posen.

REUT, a town of Bavaria, in the bishopric of Bamberg; three miles E. of Forchheim.—Also, a river of European Turkey, which runs into the Dniester, near Ustia, in the province of Moldavia.

REUTELE, in *Ichthyology*, a name used by some for the *umbla minor*, or red charr, a fish common in the lakes of Germany, and of the northern parts of England and Wales. The name is originally German.

REUTLINGEN, in *Geography*, a town of Wurtemberg, on a small river, which runs into the Neckar. It has only one parochial church, together with one hospital, an orphan-house, and a grammar-school. The magistrates and burghers are Lutherans. Near it was discovered, in 1716, a sulphurous spring; 32 miles W. of Ulm. N. lat.  $48^{\circ} 30'$ . E. long.  $9^{\circ} 8'$ .

REUTO, a town of Saxony, in the Vogtland; 6 miles W.S.W. of Plauen.

REUTTE, a town of Germany, in the county of Bregentz; 9 miles S.S.E. of Bregentz.

REUTTEN, or REITA, a town of the Tyrol, on the borders of Swabia; 32 miles N.W. of Inspruck.

REVULSION, in *Medicine*, the derivation of the fluids of the body, from a part in which they are morbidly accumulated, to another part, whether near or distant.

This principle is much acted upon in the practice of medicine, although considerably less than by the advocates of the humoral pathology. These practitioners carried the principle so far as to make their evacuations generally at some point opposite and distant to the part diseased: thus, to relieve the head, they would bleed from the foot, or from the hæmorrhoidal veins about the anus; and if a pleurisy occurred in the left side, they would open a vein in the right arm; and so forth. These were mere hypothetical refinements, and have fallen into disuse in this country. Much of the practice of medicine, however, in acute and in some local chronic diseases, hinges upon the principle of revulsion. Thus, for the removal of inflammatory congestion in any internal organ, as in the lungs or brain, a counter-inflammation is excited externally in the skin of a contiguous part, by applying a blister, or a stimulating liniment, to the surface of the chest, to the neck, or on the scalp: and thus by bringing an afflux of the fluids to these external parts, which are of less importance to life, the congestion in the vessels of the more important and vital organs is diminished, and the inflammation cured. In a similar manner, the derivation of the fluids to the intestines by cathartic medicines, to the kidneys by diuretics, and to the skin by sudorifics, tends to diminish the congestion of the circulating system at large, and consequently of particular organs. Blood-letting, whether by directly opening the veins and small arteries, or by the application of leeches, or of cupping-glasses after scarification, likewise operates upon the principle of revulsion.

Considerable errors, however, have been committed, especially by the humoral pathologists, by carrying this doctrine too far. For in their attempts to procure evacuations of the fluids, especially from the skin, they have employed heat, and ammoniacal, spirituous, and other stimulant medicines, which, by the excitement and irritation which they

occasioned in the nervous and vascular system, produced much more inflammatory action, than the revulsion, resulting from the evacuation, could possibly subdue. See *HUMORAL Pathology*.

REVULSION is also used for a spontaneous turn or reflux of humours in the body. Sudden diseases are occasioned by great revulsions of humours, which fall all at once on certain parts.

REWANH, in *Geography*, a town of Hindoostan, in the country of Allahabad; 57 mil-s S.S.W. of Allahabad. N. lat. 24° 35'. E. long. 81° 36'.

REWARDS. Military rewards, among the Athenians, consisted sometimes in crowns presented to those that had merited them: on which their names and noble actions were inscribed. Some had leave granted them to erect pillars or statues in honour of some god, with inscriptions setting forth their victories. This was a favour that was seldom granted; Cimon indeed was honoured with it, but Themistocles could never obtain the like. Another honour conferred at Athens on the valiant, was to have their arms placed in the citadel, and to be called *Cecropidae*, or citizens of the true old blood. Others were presented with a *πανοπλια*, or complete suit of armour. Songs of triumph were honorary compliments paid to some. The children of those who were killed in battle were maintained at the public expence, till they came to maturity; at which time they were presented before the assembly of the Athenian people with a complete suit of armour, one of the public ministers proclaiming before them, "that hitherto, in remembrance of their fathers' merits, the commonwealth had educated these young men, but now dismissed them so armed, to go forth and thank their country by imitating their fathers' examples."

Solon made a farther provision for the parents of those that died in the wars, it being extremely reasonable that they should be maintained at the public expence, who had lost their children, the comfort and support of their declining age, in the service of the public.

As for those who were any wife disabled, they had an allowance from the public towards their maintenance. Potter, vol. ii.

Triumphal honours were reckoned among the military rewards which the ancients voted to their best generals. Fabius Maximus, Paul Emilius, Camillus, and the Scipios, were satisfied with this recompence for their services. With respect to old infirm soldiers, who were invalided, they were provided for by receiving, each, a lot of ground, which they cultivated and improved. Lands, thus appropriated, formed part of the republican or national domains, or were divided amongst them in the conquered countries.

The Roman officer was rewarded for his services, or for particular acts of bravery, in three ways: 1st. By marks of honour or distinction, which consisted of two sorts, *viz.* of that which was merely ornamental to their own persons, or limited to the investiture for life; and of that which may be called *rememorative*, such as statues, &c. The latter descended to their posterity, and gave their families a certain rank in the republic. 2dly. By pensions or allowances. And 3dly. By a grant of lands which exceeded the lots given to private soldiers.

The French, who got possession of the country which was formerly occupied by the Gauls, had, at first, no other method of recompensing their generals than by giving them a certain proportion of land. This grant did not exceed their natural lives, and sometimes it was limited to the time they remained in the service.

These usages insensibly changed, and by degrees it became customary for the children of such men as had received

grants of national territory, to continue to enjoy them; upon condition, however, that the actual possessors of such lands should be liable to military service. Hence the origin of siefs in France, and the consequent appellation of *milice des siefs*, or militia, composed of men who held their lands on condition of bearing arms when called upon. The French armies were for many years constituted in this manner; and the custom of rendering military service in consideration of land tenure, only ceased under Charles VII.

In process of time, those lands which had been originally bestowed upon men of military merit, descended to their children, and were gradually lost in the aggregate lots of inheritable property. Other means were consequently to be resorted to by the state, in order to satisfy the just claims of deserving officers and soldiers. The French, therefore, returned to the ancient custom of the Romans, and rewarded those, who distinguished themselves in war, by honorary marks of distinction.

Honorary rewards and compensations for service were not confined to individual officers and soldiers. Whole corps were frequently distinguished in the same manner. When several corps acted together, and one amongst them gave signal proofs of gallantry and good conduct, that one frequently took precedence of the others in rank, or was selected by the sovereign to be his personal guard. Sometimes, indeed, the king placed himself at the head of such a corps on the day of battle, thereby testifying his approbation of their conduct, and giving a proof of his confidence in their bravery.

It is now usual, in most countries, to confer marks of distinction on those corps that have formed part of any army that has signalized itself. Thus the kettle-drums, under the appellation of *macaires*, were given to some regiments, as proofs of their having behaved gallantly on trying occasions.

The military order of St. Louis, which was created by Louis XIV. in 1693, and that of Maria Theresa, as well as many other orders in different countries, were only instituted for the purpose of rewarding military merit. The establishment of hospitals for invalids, such as Chelsea, &c. owes its origin and continuance to the same just sense of what is due to deserving officers and soldiers. Hence, likewise, our invalid companies and retired lists.

Philip Augustus, king of France, first formed the design of building a college for soldiers who had been rendered infirm, or were grown old in the service. Louis, furnished the Great, not only adopted the idea, but completed the plan in a grand and magnificent style. Charles II. on his restoration to the crown of Great Britain, established Chelsea, and James II. added considerable improvements to this royal institution. During the present reign, military merit has been rewarded by titles and pensions; but, what is still more creditable to the government, and reflects honour upon his royal highness the duke of York (for his co-operation with those who originally suggested the idea) old and meritorious soldiers are taught to expect a secure retreat in the decline of life; and every rank is provided for according to the claims and services of individuals.

REWARDS, in a *legal sense*. There are rewards given in many cases, by statute, for the apprehending of criminals, and bringing them to justice; as a reward of 40*l.* to those who apprehend robbers on the highway, and prosecute them to conviction, by 4 & 5 W. & M. c. 8, to be paid to them (or, if killed in the endeavour to take them, their executors) by the sheriff of the county; to which the statute 8 Geo. II. c. 16. superadds 10*l.* to be paid by the hundred indemnified by such taking. Also the like reward of 40*l.* for apprehending

hending and profecuting of burglars. Stat. 5 Ann. cap. 31. See LARCENY.

The fame reward for apprehending of money-coiners, or clippers, &c. 6 & 7 W. III. And the like reward for the apprehenfion of thief-takers, not profecuting felons; and of perfons refifting the officers of the customs, by force of arms, &c. 6 Geo. I. cap. 20. 22. See DISCOVERY of Accomplifhes.

REWARI, in *Geography*, a circar of Hindooftan, in the Subah of Delhi, between Ballogiftan on the N. and Mewat on the S.—Alfo, a town of Hindooftan, and capital of the forementioned circar; 48 miles S.W. of Delhi. N. lat. 28° 13'. E. long. 36° 52'.

REWEE, a term among *Clothiers*, fignifying cloth unevenly wrought, or full of *rewes*. 43 Eliz. cap. 10.

REX AMARORIS, in *Botany*, Rumph. Amboin. v. 2. 129. t. 41, a shrub or tree, fo called on account of its fupreme bitternefs, as well as its reputed medical virtues. The natives of Ternate, according to Rumphius, esteem it a perfect panacea. In cholera, pleurify, and various kinds of fevers, it is particularly recommended. The fruit, of a compressed heart-like fhape, and coriaceous texture, is cut into fmall pieces, and chewed with Betle-nut. Its exceffive bitternefs caufes a naufea, fuppofed to be beneficial to the patient. Linnæus cites the above chapter of Rumphius, in his *Syst. Veg.* under *Ophioxylon*, but incorrectly, *Rex amoris*. A fpecimen of the true plant is found in his herbarium, but it has no affinity to *Ophioxylon*. We have a more perfect fpecimen, gathered in the ifland of Honimoa, by the late Mr. Christopher Smith, in March 1797, by which the plant feems to belong to *Pentandria Digynia*. The leaves are elliptical, entire, a fpan long, alternate, on long ftalks; their under fides filky, efpecially when young; with one ftout midrib, and many ftraight parallel tranfverfe veins. Flowers very fmall, in numerous, fimple, filky, axillary, folitary clufters. Calyx minute, apparently of only two acute leaves. Petals five, larger than the calyx, uniform, oblong, concave, at length reflexed. Stamens awl-fhaped, fimple. Anthers roundifh, fimple, two-lobed. Germen fuperior, obovate, compressed, cloven at the top. Styles none. Stigmas obtufe, converging. The ripe fruit we have not feen. Rumphius fays it confifts of two cells, with a white feed, like that of a cucumber, in each. The foliage bears confiderable refemblance to fome of the *Contortæ*, but there is no character of that tribe in the fructification; as far, at leaft, as we can difcern. The germen and ftigmas are not unlike thofe of *Ulmus*. The half-formed fruit proves intenfely bitter, as foon as it is put into the mouth.

REX *Minftrellorum*, king of the minftrels. About the year 1330, the minftrels of Paris formed themfelves into a company, and obtained a charter. The police frequently repressed their licentioufnefs, and regulated their conduct. Philip Auguftus banifhed them the firft year of his reign; but they were recalled by his fucceffors, and united under the general name of *meneftraudie*, minftrelfy; having a chief appointed over them who was called king of the minftrels. Lewis IX. exempted them from a tariff or toll at the entrance into Paris, on condition that they would fing a fong, and make their monkies dance to the tollman, perhaps to prove their title to fuch indulgence; and hence arofe the well-known proverb, “Payer en gambades et en monnoie de finge.”

The affociated minftrels inhabited a particular ftreet, to which they gave the name, which it ftill retains, of St. Julien des Meneftriers. It was here that the public were provided with muficians for weddings, and parties of pleafure; but as a greater number of them ufually attended on fuch occafions

than were ordered, and all expected to be paid the fame price, William de Germont, provoft of Paris, in 1331 prohibited the jongleurs and jonglerelles from going to thofe who required their performance in greater numbers than had been ftipulated, upon a fevere penalty. In 1395 their libertinifm and immoralities again incurred the cenfure of government, by which it was ftremely enjoined that they fhould henceforth, neither in public nor private, fpeak, act, or fing any thing that was indecorous or unfit for modeft eyes and ears, upon pain of two months' imprifonment, and living on bread and water.

In the reign of Charles VI. they feem to have relinquifhed the juggling art, and to have confined themfelves more particularly to the practice of mufic. It was about this time that treble and bafe rebecs, or violis with three ftrings, began to be in ufe, either to play in octaves to each other, or perhaps in a coarfe kind of counterpoint, of which the laws were now forming; on this occafion the minftrels affumed the title of players on high and low inftruments (*joueurs des inftrumens tant haut comme bas*), which feems to imply treble and bafe inftruments. And the charter under this denomination was confirmed in 1401.

REX *Mullorum*, in *Ichthyology*, a name given by fome authors to a fpecies of mullet, diftinguifhed from all the others by its having a prominent belly, and having no beards under the mouth.

REX *Sacrificulus*, the *King-priest*, in *Mythology*, was inftituted, after the expulfion of the kings of Rome, to perpetuate the memory, according to Dionyfius Halicarnaffeus, of the great fervices fome of their kings had doue to Rome. A law was made, that the pontiffs and augurs fhould choofe one of the eldeft to have the charge of divine worfhip; but for fear that the name of king fhould again create jealousy, it was appointed at the fame time, that the rex sacrificulus fhould be fubject to the high priest. He had likewife the name of “Rex Sacrorum,” and his wife that of “Regina Sacrorum.” The firft perfon that was chofen under this appellation, after the expulfion of the Tarquins, was Maxim Papius, of Patrician extraction.

REX, in *Ornithology*, a fpecies of *Turdus*; which fee.

REX *Vulturum*. See VULTUR *Papa*.

REY, in *Geography*, a town of Perfia, in the province of Irak, called *Rae*; which fee.

REY, a river of England, in Wiltfhire, which runs into the Thames, near Cricklade.

REY *Ifle*, a fmall ifland in the bay of Panama. N. lat. 8°. W. long. 79° 46'.

REY *Grafts*, in *Agriculture*, a hardy early fort of grafts, much efteemed among farmers. See LOLIUM *Perenne*, and RAY *Grafts*.

REYES, in *Geography*, a town of New Navarre; 64 miles S. of Cafá Grande.—Alfo, a town of Peru, in the Audience of Lima; 12 miles N. of Tarma.

REYES, *Los*, a town of South America, in the province of St. Martha; 140 miles W. of Maracaybo. N. lat. 10° 15'. W. long. 73° 30'.—Alfo, a fmall ifland near the coaft of Patagonia, at the entrance of Port Desire. S. lat. 47° 50'.

REYES *Magos*, a town of Brazil; 40 miles N. of Spiritu Santo.

REYES *le Yapey*, *Los*, a town of South America, in the province of Buenos Ayres; 180 miles S.E. of Corrientes.

REYGADA, a town of Portugal, in the province of Beira; fix miles N.N.E. of Pinhel.

REYGATE, or REIGATE, a borough and market-town in the weft half hundred of Reygate, and county of Surrey, England, is fituated at the diftance of 19 miles eaft from Guilford,

## REYGATE.

Guilford, and 21 south by west from London. It is of great antiquity, and is mentioned in the General Survey by the appellation Chercchelle, or Chercchfield; but it soon afterwards became generally known by that of Ridge-gate, since corrupted into Reygate. The manor was formerly vested in the crown; and, previous to the Conquest, constituted part of the property settled by king Edward the Confessor on his queen, Edith. King William Rufus granted it to the illustrious family of the Warrens, earls of Warren and Surrey, several of whom obtained considerable privileges for the town. John, earl of Warren, in the reign of Edward II. procured for the inhabitants the charter, under which they now enjoy the right of holding a weekly market on Tuesday. Another, held on the first Wednesday of every month, was established by charter from Charles II.; it was for many years disused, but has lately been revived.

Reygate is a borough by prescription only. The government is vested in a bailiff, constable, tythingman, ale-taster, flesh-taster, fish-taster, and leather-seller, with a constable for the foreign division, and a tythingman for each of the forensic subdivisions, or tythings. This town originally sent members to parliament in the twenty-third year of Edward I. The electors are the freeholders of messuages or burgage tenements within the precincts of the borough, and the bailiff is the returning officer.

The parish of Reygate is divided into two capital precincts, which provide separately for the maintenance of their respective poor, *viz.* the borough and the forensec, or foreign, the latter including all that portion of the parish not comprehended in the former. Within the precinct of the borough stands the town itself, which is seated at the base of a steep hill of chalk. The buildings are principally disposed in two long and spacious streets, of which one, called the High-street, runs in a direction from west to east; and the other, called Bell-street, in a direction from north to south. The parish church, placed at a small distance from the town, although not distinguished for its antiquity or elegance of its architecture, is nevertheless one of the best ecclesiastical structures in the county. It is divided into a nave, two side aisles, and a chancel, with an embattled tower at the west end. The nave and chancel are separated from the aisles by seven pointed arches; five of which, on each side, are in the nave and two in the chancel; those of the former being supported by pillars, alternately round and octagonal; and those of the latter by clustered pillars of a more elegant form. Every portion of the interior is crowded with monuments and inscriptions to the memory of the Thurlands, of Thurland Castle in Nottinghamshire, the Jameses of Reygate, the Skinners of the same place, and others of less note. In a vault under the chancel, constructed by William, first baron Howard of Effingham, are deposited many leaden coffins, containing the remains of the founder, and of several of his descendants, earls of Nottingham, and their families. The most remarkable of these is that inscribed to the memory of Charles Howard, earl of Nottingham, who commanded the British fleet in the memorable contest with the Spanish armada, A. D. 1588.

The old market-house stood at the west end of the town, but it having gone to decay, the present house was erected, by sir Joseph Jekyll, near the site of the ancient priory, which formed one of the terminations of Bell-street. This religious establishment was founded by William de Warren, earl of Surrey, and Isabel his wife, about the year 1230. The inmates consisted of a prior, and a few canons regular, of the order of St. Augustine, whose clear annual revenue, at the time of the dissolution, amounted to 68*l.* 16*s.* 8*d.*

After that event the site of the priory, with its appurtenances, was granted by king Henry VIII. to William, lord Howard, in exchange for the rectory of Tottenham in Middlesex. The other religious buildings here were, two chapels, dedicated to St. Lawrence, and to Thomas à Becket, and the hospital of the Holy Cross, which seems to have been connected with the priory.

On a considerable eminence to the north of the town, stood the ancient castle of Reygate, the foundation and history of which are little known. Most of the very slender accounts of it which have reached our times, ascribe its origin to some of the more ancient earls of Warren and Surrey, but others assert, that the original structure was of much earlier date, and the work of our Saxon ancestors. Indeed, if the inhabitants of this part of the country were so active and successful in repelling the Danish invaders, as to give rise to the proverb attributed to them by Camden, "The Vale of Holmesdale,—never wonne, ne never shall," it seems not improbable, considering also the importance and advantage of the situation, that their leaders had a fortress here sufficient for the purposes of rendezvous and security. It is certain that there was a fortress at Reygate, of considerable note, under the earls of Warren, and which seems to have been for many years one, at least, of the capital seats of their barony. William, earl of Warren, who possessed it in king John's time, is the first of the family spoken of by Dugdale as the proprietor of it; and he acknowledges his title to be derived from his earliest ancestors. This earl, in the contest between that king and his barons, was one of the neutral lords who joined in the confederacy against the king with reluctance, and who, at the great council at Runnymede, were inclined to favour him; and by whose advice the great charter was eventually signed by him. This dubious policy of the earl occasioned the loss of his castle at Reygate, which, soon after the landing of Louis the dauphin, was surrendered to him. When it was first dismantled is uncertain, but it is mentioned as having been decayed and ruinous in the reign of James I. Even then, and for some time after, it must have been capable of defence, as in the time of the civil wars, A. D. 1648, the committee of the house of commons were ordered "to take care of it, and to put it into such a condition, that no use might be made to the endangering the peace of the kingdom." What the immediate result of these orders was we are not informed, but it was probably demolished soon afterwards, though a small part of the walls was standing within the last forty years. Now, however, every vestige of these is gone; but the vallum and ditch are still nearly entire on the south and west sides; and in the centre of the area is a descent, by a slight of steps, to a passage 235 feet long, which leads into a cave 123 long, 13 wide, and 11 high. This cave is conjectured to have served the double purpose of a repository for military stores, and a place of custody for prisoners: it might also be a place of safety in times of public commotion.

The park at Reygate is situated to the south of the town. It contains about 150 acres, and appears, by a survey made in 1622, to have been then well stored with timber trees, and with venison. It was deparked within twenty years from that period, and now retains few of its former characteristics, except the name. At East-Beechworth, to the westward of Reygate, is a seat of the late Hon. William Henry Bouverie, which was built by sir Ralph Freeman in the reign of James I.; and near it is Wontham, a mansion belonging to viscount Templetown; Gatton, to the northward, about two miles, affords an example of nominal borough representation, scarcely a house being left standing within its limits. In this parish, at a place called

Battle-bridge, tradition affirms that a great slaughter of the Danes took place. Aubrey states that a castle existed here, but no traces of such a building can now be discovered. See GATTON.

Merstham, to the east of Gatton, is noted for its stone quarries, which were anciently held in such high repute that the crown deemed it expedient to keep them in its own possession. A great part of Windsor castle, and the magnificent chapel of Henry VII. at Westminster, were constructed with stone from these quarries. The quality which renders it peculiarly valuable, is its effectual resistance against fire, whence it is denominated fire-stone. It is very soft when first raised from the quarry, but becomes indurated by exposure to the atmosphere. A rail-road has been formed here to facilitate the conveyance of stone and lime from the quarries to the metropolis. Merstham-place is a spacious mansion belonging to Hylton Jolliffe, esq. In the parish of Newdigate, about six miles south-west from Reigate, is Ewood, a mansion lately erected by the present duke of Norfolk. The house stands on the brow of an eminence, and is surrounded by a park containing about 600 acres of ground, and ornamented with a fine lake, covering sixty acres. At Nutfield, as well as at Reigate, are some fuller's-earth pits, which yield excellent earth. History and Antiquities of the County of Surrey, by the Rev. Owen Manning; edited, with additions, by W. Bray, esq. F.S.A.; vol. i. folio. Beauties of England and Wales, 8vo. vol. xiv. by I. Shorbel.

REYHER, SAMUEL, in *Biography*, an eminent German mathematician, was born at Schleusingen, in Saxony, in the year 1635. He received the early part of his education under his father, and then pursued his mathematical studies at the university of Leipzig. He next went to Leyden, and studied the algebra of Vieta under the celebrated James Golius, with whom he contracted an intimate friendship. On his return to Leipzig, he obtained so high a reputation in teaching the mathematics, that he was nominated preceptor to the young prince of Gotha, the eldest son of the duke of Saxe-Gotha. In 1665 he accepted an invitation to fill the mathematical chair at the university of Kiel, and having first paid a visit to Leyden, he was there admitted to the degree of doctor in civil law. In a few years afterwards he was appointed professor extraordinary of civil law, in 1683 professor in ordinary of the Institutes, and in 1692 professor of the code of Justinian. He died in 1714, in the 80th year of his age. He translated the works of Euclid into the German language, illustrating the geometrical with algebraical demonstrations, wherever they would admit of it; and he published, among many other works, a learned work entitled "Mathesis Biblica;" and a very curious "Dissertation concerning the Inscription on the Cross of Jesus Christ, and the Hour of his Crucifixion." Moreri.

REYN, JAN DE, or RHENI, called also *Lang Jan*, was an artist of very considerable merit, a disciple, and skilful imitator, of Vandyke; to whom he was so much attached that he followed him to London, and remained some time with him. He was born at Dunkirk in 1610; and he so effectually benefited by the instructions of Vandyke, that his pictures are frequently sold for those of that master. But as he, in general, painted history more than portrait, he has a freer line in composition, though not so correct a one as his master. His works are scarce, though he lived to the age of 68, but their apparent scarcity is possibly owing to so many of them being imputed to Vandyke. Among the works which are indisputably his, are mentioned the Baptism of Totila, which is in a church at Dunkirk; and a grand altar-piece in the parish church of St. Martin, at

Bergues, representing Herodias bringing the head of St. John to Herod. He died in 1678.

REYNA, CASSIODORUS DE, celebrated for being the first translator of the whole bible into the Spanish language, and on this account he is noticed, though we have no particulars concerning his life. To his translation he introduced notes explanatory and critical. The place where this version was printed is not mentioned in the title-page, though, from some typographical marks, it may be ascertained pretty correctly that it was at Basil; and as the author was probably a Protestant, he thought proper to conceal his name, that it might not prevent his work from being received among the Spanish Catholics, and it has only his initials R. C. to a Latin preface, recommending it to the kings, princes, and nobles of Europe, and particularly of the Roman empire. The date is 1569, and it is entitled "La Biblia, Que Es, Los Sacros Libros Del Vieio y Nuevo Testamento. Tradladada en Espagnol." The first edition of this version is now very scarce. Moreri.

REYNEAU, CHARLES RENÉ, an eminent French mathematician, was born at Brissac, in the province of Anjou, in the year 1656. At the age of twenty, he took up his residence in the house belonging to the congregation of the Oratory at Paris, without any intention of entering into the community. His object was to enjoy the advantages in study which that celebrated order afforded for improvement in literature. In a short time, however, a change took place in his mind, and he became a member of the house. He became strongly attached to the science of geometry, and in 1683 he was appointed to a mathematical professorship at Angers: this post he retained 22 years with extraordinary reputation. In this situation he undertook to reduce into one body, for the use of his scholars, the principal theories scattered through the writings of Descartes, Leibnitz, Bernouilli, the Leipzig Acts, the Memoirs of the Paris Academy of Sciences, and other works. The fruit of this undertaking, entitled "The Analysis demonstrated, &c." he published at Paris in the year 1708, in two vols. 4to. He assumed this title for his work because it contained demonstrations of several methods of analysis which had not been demonstrated by the authors of them, or, at least, not with sufficient perspicuity and exactness. By supplying what was left undone by other persons, he rendered so signal a service to mathematical students, that it became a maxim, at least in France, that to follow father Reyneau was the best way to make much progress in mathematics. Hence he was esteemed the Euclid of the sublime geometry. His great work was reprinted in 1738. In the year 1714 he drew up an elementary work on the subject, under the title of "The Science of Calculation, &c." which was most favourably received. This came out in one volume, and he had prepared materials for a second, which did not make its appearance till after the author's death. In 1716 the Royal Academy of Sciences at Paris admitted some new members, under the designation of "free associates:" father Reyneau was of that number, and he frequently assisted at their meetings. He died in 1723, at the age of 72. regretted as well for his many virtues, as for profound and extensive learning. The first men in France for talents deemed it an honour to count Reyneau among their friends. In this number was father Malebranche, of whom Reyneau was a zealous disciple. He left behind him a treatise on "Logic, or the Art of Reasoning," which was published in 1745. Moreri.

REYNEL, in *Geography*, a town of France, in the department of the Upper Marne; 12 miles W. of Bourmont.

REYNESBURCH, a town of Holland; three miles N.W. of Leyden.

REYNOLDS,

## REYNOLDS.

REYNOLDS, *Sir Joshua, Knt.*, in *Biography*, was the son of the Rev. Samuel Reynolds, rector of Plympton, near Plymouth, in Devonshire, and was born there, on July 16, 1723; the tenth of eleven children, five of whom died in their infancy. He was, for some time, instructed in the classics by his father, and was intended for the practice of physic; but he began, at a very early age, to display an inclination for the art in which he subsequently made so distinguished a figure. At eight years of age he made himself so far master of perspective, as to draw his father's bookcase according to rule, and, encouraged by his affectionate parent, amused himself by copying prints that he found in books, and particularly those in Jacob Kat's emblems. From these early labours the transition was easy to the attempt at drawing likenesses of his friends, and in these he obtained tolerable success. Richardson's Treatise on Painting was then put into his hands, and, according to his own report, he was, by that work, stimulated to the greatest degree of enthusiasm for the art of painting, and led to regard its professors, particularly Raphael, as among the greatest and most illustrious of men, either in ancient or modern time. After he had spent some time practising in the neighbouring country, his parents were induced, by the advice of a Mr. Cranch, to send him to London, as the place best calculated to improve talents such as he had so decidedly exhibited; and accordingly, in October 1741, he first visited the capital, and was immediately placed with Mr. Hudson, the most renowned portrait painter of that time, in order to acquire the first rudiments of this art.

Whatever was the cause, whether, as it is said, Hudson became jealous of the ability of his pupil, or, as is equally probable, the pupil became disgusted with the want of taste exhibited by his master, in little more than two years they disagreed, and young Reynolds returned to his father, and again employed himself in painting his friends. Many of these early productions of his pencil are still to be seen in the town and neighbourhood of Plymouth, and some of them possess very considerable merit, and indicate his future prowess. One of them, particularly, of a boy reading in reflected light, 30 years afterwards, excited surprise in his own mind, and an expression of regret that, in so many years, he should have made so little progress in his profession. He is said to have lamented having passed this period of his life in the way he had done; most probably, however, that regret alludes to his absence from London, where he would most undoubtedly have seen more of the art, and learnt more of its practice, than elsewhere. But perhaps it was a fortunate occurrence that he was removed to a station where he had to rely upon his own emotions, unbiassed by the gross and barbarous taste which then prevailed; since, guided by those emotions, he attempted to follow the dictates of nature, untrammelled by the pedantry of amateurs, and the low ignorance of the greater part of the professors of the day.

Finding his practice increasing, he took a house at Plymouth Dock, and there became known to the family of Mount Edgumbe, by whom he was warmly patronized, and recommended to captain (afterwards lord) Keppel, who carried him to Italy in 1749; and it would appear, from a letter of his to lord Mount Edgumbe, written when he was in Rome, that that noble lord defrayed the expence of his residence there. The course of his studies during the three years that he spent there, is not precisely known. He made some few copies of figures and heads from the works of Raphael, but that does not appear to have been a favourite mode of study with him, for in one of his lectures he has said, "the man of true genius, instead of spending

all his hours, as many artists do while they are at Rome, in measuring statues, and copying pictures, soon begins to think for himself, and endeavours to do something like what he sees. I consider general copying as a delusive kind of industry; the student satisfies himself with the appearance of doing something; he falls into the danger of imitating without selecting, and of labouring without any determinate object: as it requires no effort of the mind, he sleeps over his work; and those powers of invention and disposition, which ought particularly to be called out and put in action, lie torpid, and lose their energy for want of exercise. How incapable of producing any thing of their own, those are, who have spent most of their time in copying, is an observation well known to all who are conversant in our art." That he reflected deeply on the great works of the ancient and modern masters is evident, both from his pictures and writings; though the taste with which he subsequently applied the knowledge he had acquired, proves the originality of his mind, and the extent of his genius.

Mr. Reynolds returned through Paris to England in October 1752, and after a short time spent at his native place, to recruit his health, which had somewhat suffered by the journey, he fixed his settled residence in the metropolis; taking a house in St. Martin's-lane. He there painted, as his first essay, a head, from an Italian youth he had brought over with him, (Giuseppe Marchi). He dressed it in a rich turban, and its execution excited so much attention, that his old master, Hudson, was induced to go to see it, and carefully watched its progress: when, upon seeing at length no trace of his own manner left, and unable, or unwilling, to find any other merit in it, he exclaimed, "why Reynolds, you don't paint so well as you did when you left England!" Notwithstanding this augural declaration, the pupil became the superior favourite with the public; and Hudson retiring, left him without a competitor.

In 1753, or 4, he took a large house in Newport-street, where he resided for eight or nine years, and there he painted a whole length portrait of his friend commodore Keppel walking on the sea-shore, which drew upon him universal admiration, and fixed him completely in the public esteem. At this time his price was ten guineas for a head; in 1755 he raised it to twelve; and in 1758 to twenty guineas; and he afterwards, by degrees, advanced it to fifty; at which it remained till he declined practice; the price of a half length, during the latter period, being 100, and for a whole length 200 guineas.

To say that he was universally regarded as being at the head of the profession of portrait painting at the time adverted to, cannot indeed be considered as any great praise, such was its degraded condition; though Hudson had certainly advanced above his immediate predecessors. Reynolds however, deserved much more, for he united to a dignified characteristic resemblance of the head, an endless variety of spirited and graceful attitudes, picturesque back-grounds, novel and striking effects of light and shade, with a voluptuous richness and harmony of colour, which certainly had never before been seen united to so many other qualities in that branch of the art. It must not, however, be understood, that his performances at that time possessed those excellencies to the degree in which we find them in his latter works; for he was one of the few, whose efforts ended but with his life; who has been heard to say, that he never began a picture without a determination to make it his best; and whose unceasing progress almost justified the maxim he was so fond of repeating continually, "that nothing is denied to well directed industry." Besides his uncommon

affiduity, which was apparent to all, little information remains to us of the precise method of study by which such extraordinary excellence was attained, except what may be collected from the following extract, made from some papers left by him, and intended perhaps for insertion in another discourse; in which, as his biographer observes, he speaks of his merits and defects with singular modesty and candour. "Not having the advantage of an early academical education, I never had that facility of drawing the naked figure which an artist ought to have. It appeared to me too late when I went to Italy, and began to feel my deficiencies, to endeavour to acquire that readiness of invention which I observed others to possess. I consoled myself, however, by remarking, that those ready inventors are extremely apt to acquiesce in imperfection, and that if I had not their facility, I should, for this very reason, be more likely to avoid the defect which too often accompanied it,—a trite and common-place invention. How difficult it is for the artist who possesses this facility to guard against carelessness and common-place, is well known; and in a kindred art, Metastasio is an eminent instance, who always complained of the great difficulty he found in obtaining correctness, in consequence of his having been in his youth an *improvvisatore*. Having this defect constantly in my mind, I never was contented with common-place attitudes or inventions of any kind. I considered myself as playing a great game; and instead of saving money, I laid it out faster than I got it, in purchasing the best examples of the art that could be procured; for I even borrowed money for this purpose. The possessing portraits by Titian, Van-dyke, Rembrandt, &c. I considered as the best kind of wealth. By studying carefully the works of great masters, this advantage is obtained: we find that certain niceties of expression are capable of being executed, which otherwise we might suppose beyond the reach of art. This gives us a confidence in ourselves, and we are thus incited to endeavour at not only the same happiness of execution, but also at other congenial excellencies. Study, indeed, consists in learning to see nature, and may be called the art of using other men's minds. By this kind of contemplation and exercise, we are taught to think in their way, and sometimes to attain their excellence. Thus, for instance, if I had never seen any of the works of Correggio, I should never, perhaps, have remarked in nature the expression which I find in one of his pieces: or if I had remarked it, I might have thought it too difficult, or perhaps impossible, to be executed.

"My success and continual improvement in my art (if I may be allowed that expression), may be ascribed, in good measure, to a principle which I will boldly recommend to imitation; I mean a principle of honesty, which in this, as in all other instances, is, according to the vulgar proverb, certainly the best policy. I always endeavoured to do my best. Great or vulgar, good subjects or bad, all had nature; by the exact representation of which, or even by the endeavour to give such a representation, the painter cannot but improve in his art.

"My principal labour was employed on the whole together, and I was never weary of changing and trying different modes and effects. I had always some scheme in my mind, and a perpetual desire to advance. By constantly endeavouring to do my best, I acquired a power of doing that with spontaneous felicity, which at first was the effort of my whole mind, and my reward was three-fold; the satisfaction resulting from acting upon this just principle, improvement in my art, and the pleasure derived from a constant pursuit after excellence.

"I was always willing to believe that my uncertainty or proceeding in my works, that is, my never being sure of my hand, and my frequent alterations, arose from a refined taste, which could not acquiesce in any thing short of a high degree of excellence. I had not an opportunity of being early initiated in the principles of colouring; no man, indeed, could teach me. If I have never been settled with respect to colouring, let it at the same time be remembered, that my unsteadiness in this respect proceeded from an inordinate desire to possess every kind of excellence that I saw in the works of others: without considering that there are in colouring, as in style, excellencies which are incompatible with each other: however, this pursuit, or any similar one, prevents the artist from being tired of his art. We all know how often those masters who sought after colouring changed their manner, while others, merely from not seeing various modes, acquiesced all their lives in that in which they set out. On the contrary, I tried every effect of colour; and by leaving out every colour in its turn, shewed every colour that I could do without it. As I alternately left out every colour, I tried every new one; and often, as is well known, failed. The former practice, I am aware, may be compared by those whose first object is ridicule, to that of the poet mentioned in the Spectator, who in a poem of 24 books, contrived in each book to leave out a letter. But I was influenced by no such idle or foolish affectation; my fickleness in the mode of colouring, arose from an eager desire to attain the highest excellence. This is the only merit I can assume to myself from my conduct in this respect."

His assiduity and love of his profession left him little leisure for country excursions. Occasionally, however, he spent a few days at his villa on Richmond-hill, and visited, at different times, the seats of some of the noblemen and gentlemen of his acquaintance, from whence he was always glad to return to the practice of his profession, and the enjoyment of that intellectual society, of which, like his friend Johnson, he justly considered London as the headquarters. He, very soon after he became settled, perceived the advantage which one confined to the laborious duties of an arduous profession might derive from the society of literary men. Finding how little time he could spare from his profession, for the purpose of acquiring general knowledge from books, he resolved to partake as much as possible of the benefits which might be drawn from the conversation of the learned and ingenious men of his time. In consequence of this, and of his cheerful and convivial habits, his table, for above thirty years, exhibited an assemblage of all the talents of Great Britain and Ireland; there being, during that period, scarcely a person in the three kingdoms distinguished for his attainments in literature or the arts, or for his exertions at the bar, in the senate, or the field, who was not occasionally found there.

Soon after the return of Sir Joshua from Italy, he became acquainted with Dr. Johnson, to whose superior talents he was always proud to acknowledge his obligations; and in the paper we have before-mentioned, had expressed his sense of the benefit he had derived from his society. When speaking of the value of associating either personally or by study with the truly great, he adds, "May I presume to introduce myself as an instance of the truth of what I have remarked. Whatever merit the discourses which I have had the honour of delivering from this place may have, it may in great measure be imputed to the education which I may be said to have had under Dr. Johnson. I do not mean to say, though it certainly would be to the credit of these discourses, if I could say it with truth, that he

contributed even a single sentiment to them ; but he qualified my mind to think justly. No man had, like him, the faculty of teaching inferior minds the art of thinking."—"The observations which he made on poetry, on life, and on every thing about us, I applied to one art ; with what success others must judge." The great leviathan of literature found in the mind of Reynolds a congenial purity and strength, and became zealously attached to him ; who, with such a coadjutor, found but little difficulty in collecting around him a circle of the most able and useful members of society. Many illustrious foreigners were personally intimate with him ; and his friendship was sought by individuals of the highest quality ; who revered his genius as much as they respected the worth of his private character. From such connections, his mind, rich in its own stores, received an accession of most extensive information, and an inexhaustible treasure for conversation. He had a mind ever open to acquire useful knowledge ; a sound and penetrating judgment to select what he acquired, and great industry and application in rendering his acquisitions useful.

The variety of talent he exhibited, and the consequent eminence which he gained, qualified him to share the honours of the first scientific institutions. He was accordingly admitted to the Royal, the Antiquarian, and the Dilettanti Societies ; and when the late lord North was installed chancellor of the university of Oxford, in July 1773, sir Joshua was admitted to the honorary degree of doctor in civil law. He had previously, in 1769, been elected to the presidency of the Royal Academy, in the formation of which he had a principal share, and had, upon the occasion, been honoured by his majesty with the rank of knighthood. To this institution he was a most invaluable member, and repaid the honour and fame he acquired from his situation in it, by a zealous attention to its interests. Nor did the Academy derive less credit from the admirable works which he continued yearly to exhibit in it, consisting indeed chiefly of portraits, though he rarely suffered a season to pass in which he did not bring forwards one or more specimens of his powers in history. From the year 1769, when, as we have said, the academy was founded, till 1790, inclusive, it appears that he sent no less than 244 pictures to the exhibition.

The task of reading lectures was no part of the prescribed duty of his office : but imposed voluntarily upon himself for the following reasons, assigned by him in his fifteenth discourse. "If prizes were to be given, it appeared not only proper, but almost indispensably necessary, that something should be said by the president on the delivery of those prizes ; and the president, for his own credit, would wish to say something more than mere words of compliment : which, by being frequently repeated, would soon become flat and uninteresting ; and by being uttered to many, would at last become a distinction to none. I thought, therefore, if I were to preface this compliment with some instructive observations on the art, when we crowned merit in the artists whom we rewarded, I might do something to animate and guide them in their future attempts." To the exertions which this most judicious sense of propriety stimulated him to make, he is indebted, principally, for his renown as an author. In the course of twenty-one years, *viz.* from 1769 to 1790, inclusive, he composed fifteen discourses ; replete with the soundest principles, and the most useful information concerning the art he practised, that ever have been given to the world. In which, though it must be acknowledged that there are some few points not sufficiently explained, yet they are free from the affected rant of connoisseurship, and practically efficient to guide the young, whilst it confirms the more ad-

vanced, in pursuit of the just objects of the art of painting, and the surest means of obtaining success. Besides these, he wrote three papers for the *Idler*, in 1759 ; *viz.* Nos. 76, 79, and 82 ; in which is exhibited his original turn of thinking on the nature and properties of beauty and of art : and in 1783, his notes to Maſon's translation of Du Fresnoy's poem on Painting, gave to the world many practical observations and explanations of the rules laid down in the text, which convey instruction of the most useful kind, and tend to shew how carefully, and how systematically, his mind was made up on the subject.

It has been conjectured, and widely diffused in opinion, that sir Joshua did not compose his lectures himself. In support of what is due to him on that head, Mr. Northcote, who lived some years in his house, has said in his memoirs, "At the period when it was expected he should have composed them, I have heard him walking at intervals in his room till one or two o'clock in the morning, and I have on the following day, at an early hour, seen the papers on the subject of his art which had been written the preceding night. I have had the rude manuscript from himself, in his own handwriting, in order to make a fair copy from it for him to read in public : I have seen the manuscript also after it had been revised by Dr. Johnson, who has sometimes altered it to a wrong meaning, from his total ignorance of the subject and of art ; but never, to my knowledge, saw the marks of Burke's pen in any of the manuscripts.

"The bishop of Rochester, also, who examined the writings of Mr. Burke since his death, and lately edited a part of them, informed a friend that he could discover no reason to think that Mr. Burke had the least hand in the discourses of Reynolds." And Burke himself, in a letter to Mr. Malone, after the publication of sir Joshua's life and works, says, "I have read over some part of the discourses with an unusual sort of pleasure, partly because being faded a little in my memory, they have a sort of appearance of novelty ; partly by reviving recollections mixed with melancholy and satisfaction. The Flemish journal I had never seen before. You trace in that, every where, the spirit of the discourses, supported by new examples. He is always the same man ; the same philosophical, the same artist-like critic, the same sagacious observer, with the same minuteness, without the smallest degree of trifling." We may safely say, this is not the language of one who had himself contributed much to those discourses. And if neither Johnson nor Burke wrote for Reynolds, to whom else among his contemporaries shall the praise due to those invaluable compositions be given, if Reynolds is to be deprived of it !

It is much to be lamented, that the world was deprived of this great artist before he had put into execution a plan which his biographer, Mr. Malone, says appears, from some loose papers, to have been revolved in his mind. "I have found," says that author, "among sir Joshua's papers, some detached and unconnected thoughts, written occasionally, as hints for a discourse, on a new and singular plan, which he seems to have intended as a history of his mind, so far as concerned his art ; and of his progress, studies, and practice ; together with a view of the advantages he had enjoyed, and the disadvantages he had laboured under, in the course that he had run : a scheme, from which, however liable it might be to the ridicule of wits and scoffers, (of which, he says, he was perfectly aware,) he conceived the students might derive some useful documents for the regulation of their own conduct and practice." Such a composition, from such a man, written after he had spent a long life in successful practice, with none to guide him ; who had chosen a line of art for himself, stamped with originality ; and in which he had to  
develope

develope principles, and elucidate them by practice; and competent as he was to explain the operations of his own mind; could not fail of being interesting and useful in the highest degree. One of these detached ideas we have quoted above, and lament that any of them should be withheld from publication.

In 1781, during the summer, he made a tour through Holland and the Netherlands, with a view of examining critically the works of the celebrated masters of the Dutch and Flemish schools. An account of this journey, written by himself, containing much excellent criticism on the works of Rubens, Vandyke, Rembrandt, &c. in the churches and different collections at Antwerp, Brussels, Ghent, the Duffeldorf gallery, and at Amsterdam, was published after his death; it concludes with a masterly drawn character of Rubens.

In 1783, in consequence of the emperor's suppression of some religious houses, he again visited Flanders, purchased some pictures by Rubens, and devoted several more days to the contemplation and further investigation of the performances of that great man. On his return, he remarked that his own pictures wanted force and brilliancy, and appeared, by his subsequent practice, to have benefited by the observations he had made. This year, on the death of Ramsay, he was made principal painter in ordinary to his majesty, and continued so till his death.

For a very long period he had enjoyed an almost uninterrupted state of good health, except that in the year 1782 he was for a short time afflicted with a paralytic stroke. A few weeks, however, perfectly restored him, and he suffered no inconvenience from it afterwards. But in July 1789, whilst he was painting the portrait of lady Beauchamp, he found his sight so much affected, that it was with difficulty he could proceed with his work; and notwithstanding every assistance that could be procured, he was in a few months totally deprived of the use of his left eye. After some struggles, he determined, lest his remaining eye should also suffer, to paint no more: and though he was thus deprived of a constant employment and amusement, he retained his usual spirits, and partook of the society of his friends with apparently the same pleasure to which he had been accustomed; and was amused by reading, or hearing others read to him. In October 1791, however, his spirits began to fail him, and he became dejected, from an apprehension that an inflamed tumour, which took place over the eye that had perished, might occasion the destruction of the other also. Meanwhile he laboured under a more dangerous disease, which deprived him both of his spirits and his appetite. During this period of great affliction to all his friends, his malady was by many supposed to be imaginary, and it was erroneously conceived, that by exertion he might shake it off; for he was wholly unable to explain to the physicians the nature or seat of his disorder. It was only about a fortnight before his death that it was found to be in the liver; the inordinate growth of which, as it afterwards appeared, had incommoded all the functions of life. Of this disease, which he bore with great fortitude and patience, he died, after a confinement of three months, at his house in Leicester-square, on Thursday evening, February 23, 1792, at the age of 69.

In stature, sir Joshua Reynolds was rather under the middle size, of a florid complexion, roundish, blunt features, and a lively pleasing aspect; not corpulent, though somewhat inclined to it; and extremely active. With manners uncommonly polished and agreeable, he possessed a constant flow of spirits, which rendered him at all times a most desirable companion: always ready to be amused, and to contribute to the amusement of others, and anxious to receive

information on every subject that presented itself: and though he had been deaf almost from the time of his return from Italy; yet, by the aid of an ear trumpet, he was enabled to partake of the conversation of his friends with great facility and convenience. On the 3d of March his remains were interred in the crypt of St. Paul's, near the tomb of sir Christopher Wren, with every honour that could be shewn to worth and genius by an enlightened nation; a great number of the most distinguished persons attending the funeral ceremony, and his pall being supported by three dukes, two marquises, and five other noblemen.

In many respects, both as a man and a painter, sir Joshua Reynolds cannot be too much studied, praised, and imitated by every one who wishes to attain the like eminence. His incessant industry was never wearied into despondency by miscarriage, nor elated into neglect by success. Either in his painting-room, or wherever else he passed his time, his mind was devoted to the charms of his profession. All nature, and all art, was his academy, and his reflection was ever on the wing, comprehensive, vigorous, discriminating, and retentive. With taste to perceive all the varieties of the picturesque, judgment to select, and skill to combine what would serve his purpose, few have ever been empowered by nature to do more from the fund of his own genius: and none ever endeavoured more to take advantage of the labours of others. He made a splendid and useful collection, in which no expence was spared. His house was filled, to the remotest corners, with casts from the antique statues, pictures, drawings, and prints, by various masters of all the different schools. Those he looked upon as his library, at once objects of amusement, of study, and competition. After his death they were sold by auction, with his unclaimed and unfinished works, and, together, produced the sum of 16,947*l.* 7*s.* 6*d.* The substance of his whole property, accumulated entirely by his pencil, and left behind after a life in which he freely parted with his wealth, amounted to about 80,000*l.*

It remains to speak of his style as an artist, which is precisely that, denominated in his lectures the ornamental style; but which, beautiful and seducing as it undoubtedly is, cannot be recommended in so unreserved a degree as his industry both in study and practice: that which he characteristically terms his own uncertainty, both in design and in execution, operates too frequently and too powerfully against its entire adoption. In the higher attainments of the art, colouring and chiaro-scuro were undoubtedly elements which he favoured, and in which he moved uncontrolled. Drawing, as he himself candidly confessed, was the part of the art in which he was most defective; and from a desire perhaps to hide this defect, with an over-solicitude to produce a superabundant richness of effect, he was sometimes tempted to fritter his lights, and break up his composition, particularly if it happened to be large, into too many parts: yet, in general, his taste in lines and forms was at the same time grand and graceful; and the taste and skill with which he drew and set together the features of the human face, has never been surpassed by any artist. We would be understood to speak of his finest productions; of the ordinary class among them, we must allow, that the marking favours of manner, and the substance is not always characteristic of flesh.

In execution, though he wanted the firmness and breadth which appertain to the highest style of art, yet the spirit and sweetness of his touch were admirable, and would have been more remarkable, had he been more a master of drawing: but not being able readily to determine his forms, he was obliged to go over and over the same part, till some of the vivacity of his handling was frequently lost; his labour,

bour, however, was never wholly so, for he added to the force and harmony of his pictures by these repetitions; and frequently attained graces by them which would otherwise perhaps have remained unknown.

The numberless instances in which he is known to have borrowed thoughts, both in actions of figures, and effect of colour, seem to impeach his power of invention. But surely it could not proceed from want of a sufficient portion of that high and necessary quality, that he, who produced so many novel combinations, adopted that short-hand path to composition. We see it exemplified in a superior degree in most of his principal productions; and particularly in his whole length and half length portraits; the arrangements of which are no less beautiful and interesting, than new, and entirely his own. These are composed in a taste far surpassing all that had ever been done by his predecessors; uniting the grandeur, simplicity, and fulness of Titian, and the grace and nature of Vandyke, with the artful and attractive effects of Rembrandt.

Most probably he adopted that line of conduct from necessity; driven to it by the immense source of employment which his talents for portraiture showered upon him. He had scarcely time to invent new actions or effects in all cases, or to bestow that study upon them which would have been requisite, and therefore he satisfied himself by endeavouring to infuse into those he borrowed more elegance, more feeling, or more sentiment. How effectually he did this, needs not here be mentioned. One quality he had, which no other painter that ever breathed shares with him in an equal degree, fascination. The effect of his best pictures acts like a charm, and arrests the tasteful beholder with irresistible power. On the works of others we look with approbation, and sometimes with feelings of admiration and delight, or even with a sensation of awe; but in those of Reynolds there is generally an indescribable unity and amenity, which act upon us with most fascinating power, and rivet the attention with superior gratification. No real connoisseur can deny the existence of this quality in his pictures, but wherein it specifically dwells, it is not easy to discover or define. They are not laboured to perfect imitation, indeed they stop very far short of that; yet they present a full image, with a degree of life and animation, that has rarely been displayed upon canvas. It is a dangerous doctrine to advance, and may be abused; but, perhaps, this power may be in great measure owing to his having painted less upon system, than from feeling; and the latter governing the exercise of his pencil, not to the neglect of, but in a superior degree to the influence of the former, necessarily imbued his works with a glow of nature; which, it will be allowed, attracts beyond the power of art. Whencesoever this fascination, of which we speak, proceeds, it must be acknowledged, that no painter ever possessed it like Reynolds.

His historical works are but few. Those, however, exhibit a power, of which it is fair to say, that if it had been early cultivated, and kept in employment, he would most probably have rivalled the great names of antiquity. His poetic and fancy subjects are treated with originality, variety, taste, and sentiment.

The sense of his extraordinary talents was revived and strengthened to its proper medium, by a most just and pleasing tribute paid to his memory in the course of the year 1813: viz. a public exhibition of a selection of his works at the gallery of the British Institution, Pall Mall. About 150 pictures, productions of his easel, collected from various possessors, were arranged for the inspection of the public; and presented an assemblage of taste and

genius, such as we conceive no other country in the world could boast. At least in an equal number of any other artist's productions, so pleasing a combination of the beauties of the art of painting could no where be found; and these were but a small proportion, indeed, of the number of pictures which he painted. There are engravings from upwards of 700 of his works, and a vast number of others have evidently never been under the engraver's hands. The idea of this token of respect to our great artist originated in conversation at the annual dinner of the Royal Academy, in 1812; when, upon its being proposed to his royal highness the prince of Wales, who was present, he entered most cordially into it, and professed his readiness to lend his own pictures for the purpose. The exhibition being prepared, it was opened on Saturday, the 11th of May, when the members of the institution gave a grand dinner to a large portion of the nobility and the members of the Royal Academy, which was honoured by the presence of the prince regent. After the dinner the rooms were illuminated by lamps, and the company increased and adorned by the admission of ladies, many of whom had been the happy subjects of his ingenious pencil: for he is said to have preferred to posterity the features of three generations of the beauty and fashion of the country.

The pleasure afforded to the country at large by this exhibition was testified by the immense concourse of people that flocked to behold and admire, during the whole time of its remaining open. So that the funds of this excellent institution were well replenished, its object of exalting the honour of the artist and his profession most amply effected, and the country itself exalted in the estimation of the world, by this effective display of native power in an art, the neglect of which had been the source of obloquy upon our climate, as it continues, notwithstanding and more justly, still to be upon our government.

We shall conclude our account of this great and valuable man, by quoting part of an eulogium written by his friend Mr. E. Burke a few hours after the melancholy event, which it commemorates, had taken place. "He possessed," said that clear investigator of character, "the theory, as perfectly as the practice, of his art. To be such a painter, he was a profound and penetrating philosopher.

"In full affluence of foreign and domestic fame, admired by the expert in art, and by the learned in science, courted by the great, caressed by sovereign powers, and celebrated by distinguished poets, his native humility, modesty, and candour, never forsook him, even on surprize or provocation; nor was the least degree of arrogance or assumption visible to the most scrutinizing eye, in any part of his conduct or discourse.

"His talents of every kind, powerful from nature, and not meanly cultivated by letters, his social virtues in all the relations and all the habitudes of life, rendered him the centre of a very great and unparalleled variety of agreeable societies, which will be dissipated by his death. He had too much merit, not to excite some jealousy; too much innocence, to provoke any enmity. The loss of no man of his time can be felt with more sincere, general, and unmixed sorrow.

"Hail! and Farewell!"

REYNOLDS' *Island*, in *Geography*, a small island in the Florida Stream. N. lat. 24°. W. long. 81° 30'.

REYNOSA, a town of Spain, in Old Castile; 35 miles N.W. of Frias.

REYOOR, a town of Hindoostan, in the circar of Condapilly; 15 miles S.E. of Condapilly.

REZ, a river of Russia, which runs into the Irbit. N. lat. 57° 50'. E. long. 62° 34'.

REZEMICO, a town of Italy, in the department of the Lario; 20 miles N. of Como.

REZITZA, a town of Russia, in the government of Polotsk; 72 miles N.N.W. of Polotsk. N. lat. 56° 25'. E. long. 27° 4'.

REZZATO, a town of Italy, in the department of the Mela; 4 miles E. of Brescia.

REZZLE, a term provincially signifying the weezle.

RHA, in *Botany*,  $\rho\alpha$ , or  $\rho\alpha$ , of Dioscorides, "which some," says he, "call  $\rho\alpha$ ," is described by that ancient writer as the produce of the countries above the Bosphorus, from whence it was brought to Greece. "The root is black externally, like the Greater Centaury, but smaller, and internally of a more reddish hue, destitute of odour, loose, fungous, and rather light." He proceeds to describe its flavour and virtues. The plant of Dioscorides has generally been supposed one of the rhubarbs of the shops, which acquired, subsequently to his time, the name of *Rha-barbarum*, because it was procured from countries deemed barbarous by the Greeks and Romans. What precise species of RHEUM (see that article) it might be, we presume not to determine. Sometimes it has been termed *Rhaponticum*; though the latter appellation has also been bestowed on a species of *Centaurea*, which Dodonæus and others have thought to be the true ancient *Rha*, or *Rheum*, and which Linnæus, therefore, names *Centaurea Rhabontica*.

RHAAD, in *Ornithology*, a species of *Otis*; which see.

RHABBARBARUM, in *Botany*. See RHA.

RHABDOIDES,  $\rho\alpha\delta\delta\omega\iota\delta\eta\varsigma$ , formed from  $\rho\alpha\delta\delta\omega\iota\varsigma$ , *rod*, or *staff*, and  $\iota\delta\omega\iota\varsigma$ , *form*, in *Anatomy*, a name given the second true future of the skull, called also the *sagittal future*.

RHABDOLOGY, or RABDOLOGY, in *Arithmetic*, a name sometimes given to the method of performing the two most difficult and operose rules, *viz.* multiplication and division, by the two easiest, *viz.* addition and subtraction, by means of two little rods or laminæ, on which are inscribed the simple numbers, and which are to be shifted according to certain rules.

These rods are what we popularly call *Niçper's bones*, from their inventor, a Scottish baron, who likewise invented logarithms. For their description and use, see *NIEPER'S BONES*.

RHABDOMANCY, an ancient method of divination, performed by means of rods or staves.

Whence its name, from the Greek  $\rho\alpha\delta\delta\omega\iota\varsigma$ , *rod*, and  $\muαν\tau\iota\varsigma$ , *divination*.

St. Jerom makes mention of this kind of divination, in his commentary on Hosea, ch. iv. 12. The same he finds again in Ezekiel, xxi. 21, 22.

If it be the same kind of divination that is mentioned in the two passages, rhabdromancy must have been also the same superstition with belomancy.

In effect, the two are ordinarily confounded. The Seventy themselves translate the  $\rho\alpha\delta\delta\omega\iota\varsigma$  of Ezekiel, by  $\rho\alpha\delta\delta\omega\iota\varsigma$ , *a rod*; though in strictness it signifies an *arrow*.

This however is certain; the instruments of divination mentioned by Hosea are different from those of Ezekiel.

In the former it is  $\rho\alpha\delta\delta\omega\iota\varsigma$ , *etso*,  $\mu\alpha\kappa\lambda\omega$ , *maklo*, his *wood*, his *staff*; in the latter,  $\rho\alpha\delta\delta\omega\iota\varsigma$ , *bbiism*, *arrows*. Though it is possible they might use rods or arrows indifferently; or the military men might use arrows, and the rest rods. It appears by the laws of the Frisones, that the ancient inhabitants of Germany practised rhabdromancy. The Scy-

thians were likewise acquainted with the use of it; and Herodotus observes (lib. iv.) that the women among the Alani fought and gathered together fine straight rods or wands, and used them in the like superstition.

RHABDONALEPSIS,  $\rho\alpha\delta\delta\omega\iota\varsigma \text{ } \text{Αναληψις}$ , among the Greeks, the Reception or Elevation of the Rod, a festival kept every year in the island of Cos, at which the priests carried a cypress-tree.

RHABDOPHORI,  $\rho\alpha\delta\delta\omega\iota\varsigma \text{ } \text{Φοροι}$ , among the Greeks, officers appointed to preserve peace and good order, and to correct the unruly at their public games.

RHABDUS,  $\rho\alpha\delta\delta\omega\iota\varsigma$ , among the *Ancients*, the iron rod with which the boys rolled the trochus.

RHACHITIS, in *Surgery*. See RACHITIS and RICKETS.

RHACOMA, in *Botany*, a name adopted by Linnæus from Pliny, and applied to the genus called by Browne *Crossopetalum*, but which proves not distinct from *MYGINDA*; see that article. The real *Rhacoma* of Pliny appears, by his copious account of its characters and qualities, to be some kind of rhubarb (see RHA and RHEUM); nor do we pretend to account for the Linnæan application of the name.

RHACOSIS, from  $\rho\alpha\chi\omega\varsigma$ , *a rag*, in *Surgery*, a ragged, excoriated, and relaxed state of the scrotum.

RHADAMANTHUS, in *Mythology*, one of the three judges or sovereigns of Hades, or the invisible world, to whom was assigned Tartarus, as Erebus was to Minos, and Elysium to Æacus. He was the brother of Minos, and the son of Jupiter and Europa; and is said to have been preferred to the honour of presiding over Tartarus, on account of the distinguished wisdom and justice of his administration.

According to Plato, Æacus judged the Europeans; and Rhadamanthus, who had left Crete, and fixed his residence in Asia, had the Asiatics for his lot, among whom were also comprehended the Africans. The stern Rhadamanthus superintends in Tartarus the execution of the sentences which his brother Minos pronounces, after shaking the fatal urn in which are contained the destinies of all mortals. The office of Rhadamanthus is described by Virgil, *Æneid*, lib. iv.

"Gnosius hæc Rhadamanthus habet durissima regna  
Calligatque auditque dolos, subigitque fateri,  
Quæ quisque apud superos, furto latatus inani  
Distulit in feram commissa piacula mortem."

RHADAMISTUS, in *Entomology*, a species of *Scarabæus*; which see. It inhabits Tranquebar.

RHADEN, in *Geography*, a town of Westphalia, in the principality of Minden; 15 miles N.W. of Minden.

RHADES, a town of Africa, in the kingdom of Tunis, anciently called "Ades;" six miles S.E. of Tunis.

RHÆTEUM, or RHETEUM, in *Ancient Geography*, a promontory in the vicinity of Troy, on which was erected a tomb to Ajax, mentioned by Strabo (l. 13.) and other ancient writers. Horace indeed says (Sat. l. 2.) that this hero remained without burial; but he deviates from the truth, in allusion to that incident in the tragedy of Ajax, where Sophocles feigns that Agamemnon was unwilling to allow the honours of burial to be conferred upon him, but that he yielded at length to the importunate intreaties of Teucer.

RHÆTIA, a country of Europe, which occupied part of the Alps, and was situated to the north of Italy, and to the east of Helvetia. It is not easy to ascertain its limits to the north, but we may say that it was bounded in that quarter by Vindelicia; and, in general, that it corresponded to the country

country of the Grisons, and to the cantons of Uri, Glaris, &c. as far as the "Brigantinus lacus," or lake of Constance: it extended also over the Tyrol. This country was called Western Illyricum, and was divided into Rætia Prima or Propria, and Secunda, extending towards Swabia, Bavaria, and Austria. This district was subjected to the Romans by Drusus, under the reign of Augustus. Soon afterwards Vindelicia took up arms in their favour, and Tiberius was sent against them, and reduced their country, so that the possessions of the Romans extended as far as the Danube. The whole of this extensive territory had borne the name of Rætia; but under Dioclesian it was divided, as we have said, into Rætia Prima and Secunda, the latter of which divisions was Vindelicia. Rætia, Noricum, and some other territories, became a Roman province, and belonged to the kingdom of the Ostrogoths in Italy; but upon the declension of it, they fell under the dominion of the Franks, about which time the name of Bavarians first became celebrated in history. The principal rivers of Rætia were the Rhenus or Rhine, the Athesis or Adige, the Oenus or Inn, the Ticinus or Tofin, and Addua. The most considerable places were Curia or Coira, at a small distance east of the Rhenus, and Tridentum or Trent, on the Athesis. Ptolemy, in his geography of Rætia, reckons upon the Danube the following towns, *viz.* Bragodurum, Dracumna, Viana, and Phæniana; and towards the source of the Rhine, Tagahum, Brigantium, Ebodunum, Drusomagus, and Ectodurum.

**RHAGADES**, *ῥαγάδες*, in *Surgery*, a Greek term used for the chaps or clefts in the lips, hands, anus, and other soft parts of the body.

Rhagades are a sort of fissures, and little chapped ulcers of the œdematous kind; formed of a sharp saline humor, and occasioning a great contraction and straightening of the part, which is by this means shrivelled up like a wet parchment, when held to the fire.

They are chiefly found on the fundament, the neck of the womb, the præputium, lips, &c. sometimes even in the mouth; in which case the patient is not able to speak, chew, or the like.

They are sometimes moist, and of a cancerous nature, eating deep, and difficult of cure; but they are more commonly of a less malignant tendency, being often in the anus the consequence of a diarrhœa, dysentery, or the like.

**RHAGADIOLUS**, in *Botany*, see **LAPSANA**; under the fourth species of which its etymology is given.

**RHAGAURA**, in *Ancient Geography*, a town of Asia, in Aria, between Siphara and Zamuchana. Ptolemy.

**RHAGE**, a word used by medical writers for a fissure or chap in any part. The stones of grapes are also by some called *rhages*; and by others the same word is made to express the extremities of the fingers or toes.

**RHAGEA**, in *Ancient Geography*, a town of Asia, in Parthia, near Appha, according to Ptolemy.

**RHAGES**, a town of Macedonia, on the banks of the river Peneus, about ten miles from Larissa, according to Livy.

**RHAGIA**, a town of Asia, in Babylonia, towards Arabia Felix, between Jamba and Chiriphe, according to Ptolemy.

**RHAGIANA**, a town of Gedrosia, near the "Portus Mulierum;" so called in the translation of Ptolemy; but in the text of Ptolemy it is called "Rapava."

**RHAGODIA**, in *Botany*, from *ραξ*, a berry, because its little pulpy fruit affords a principal mark of distinction between this genus and several others, to which it is nearly related.—Brown Prodr. Nov. Holl. v. 1. 408. Ait. Hort.

Kew. v. 5. 440.—Class and order, *Polygamia Monoecia*, Brown; but we should rather say *Pentandria Digynia*, though some of the flowers are defective as to the stamens or the pistil. Nat. Ord. *Holeracea*, Linn. *Atriplices*, Just. *Chenopodeæ*, Decandolle and Brown.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, concave, permanent, in five deep ovate segments. *Cor.* none. *Stam.* Filaments five, awl-shaped, opposite to the segments of the calyx, and about as long; anthers roundish, two-lobed. *Pist.* Germen orbicular, depressed; styles two, divaricated, short; stigmas simple. *Peric.* Berry orbicular, depressed, encompassed underneath by the calyx. *Seed* solitary, the shape of the berry, "furnished with albumen, and a double coat." Brown.

Obs. Labillardiere and Brown describe some flowers as wanting the stamens, others the pistil, though the rest have both. In this polygamous character, but especially in the nature of the fruit, which is a true *bacca*, this genus differs from **CHENOPodium**, as well as from **КОЧИА**, and other neighbouring genera, of Mr. Brown; see those articles. The stamens are sometimes fewer than five. Brown.

Ess. Ch. Calyx inferior, in five deep segments. Corolla none. Berry depressed, encompassed with the permanent calyx. Seed solitary, orbicular, depressed. Some male or female flowers are interspersed.

The species, all natives of New Holland, are generally shrubby, rarely herbaceous. Leaves almost always alternate, simple, often clothed with mealy powder. Flowers either spiked or conglomerated, destitute of bractæas.

1. **R. Billardieri**. (*Chenopodium baccatum*; Labill. Nov. Holl. v. 1. 71. t. 96.)—Shrubby, erect, without thorns. Leaves entire, linear-oblong or lanceolate, flat; powdery beneath. Spikes branched. Native of New South Wales, as well as of the southern coast of New Holland. Stem shrubby, branched, five feet or more in height, with round, leafy branches, striated when dry. Leaves stalked, spreading, an inch and a half, or two inches, long, and one-third of an inch broad, sharpish; tapering at the base. Flowers small, greenish, in terminal, much compounded, or panicled, spikes. Berries red, about the size of mustard-seed.

2. **R. crassifolia**.—Shrubby, erect, without thorns. Leaves entire, oval, or linear-oblong, fleshy, convex and powdery beneath. Spikes branched.—Gathered by Mr. Brown, on the south coast of New Holland.

3. **R. linifolia**.—Somewhat shrubby, decumbent. Leaves entire, linear-lanceolate, flat, stamens one or two. Found by the same botanist, in the tropical part of New Holland.

4. **R. hofstata**. Ait. n. 1.—Somewhat shrubby, erect. Branches diffuse. Leaves nearly opposite, hastate, somewhat rhomboid, entire, very smooth. Spikes terminal, leafless.—Native of New South Wales, from whence it was sent to Kew by Mr. Peter Good, in 1803. This is a hardy shrub, flowering with us in June and July, and appears to be the only species of the genus before us, that has, as yet, been cultivated in England.

5. **R. parabolica**.—Shrubby, erect, without spines. Leaves triangular, obtuse, powdery. Spike branched.—Observed by Mr. Brown, on the south coast of New Holland, but without fruit.

6. **R. spinefcens**.—Shrubby, erect; the young branches becoming spines. Leaves partly opposite, hastate, somewhat rhomboid, entire; powdery and hoary on both sides. Spikes simple.—From the south coast.

7. **R. nutans**.—Herbaceous, prostrate. Branches ascending when in fruit, drooping at the extremity. Leaves opposite, linear-lanceolate-hastate, acute.—Gathered by Mr. Brown,

on the south coast of New Holland, as well as in Van Diemen's island.

**RHAGOIDES**, *ῥαγοειδής*, in *Anatomy*, the second coat or tunic of the eye; more usually called uvea.

It has its name rhagoides, as resembling a grape-stone.

In the tunica rhagoides is the hole called the pupil.

**RHAHAANS**, in *History*, a name given to the priests of the Birman empire, to whom are assigned kioums, or convents; which are different in their structure from common houses, and much resemble the architecture of the Chinese. These buildings are constructed of wood; the roof is composed of different stages, supported by strong pillars; the inside comprehends one large hall; the whole house is open at the sides; some are curiously carved with various symbolic representations of the divinity. There are no apartments for the private recreation of the Rhahaans; publicity being the prevailing system of conduct among the Birmans, who admit of no secrets either in church or state. From the number of convents in the neighbourhood of Rangoon, the Rhahaans and Phonghis, who are an inferior order of priests called Tallapoints, are presumed by colonel Symes to exceed 1500; including in this estimate those in their novitiate. The age of induction into these convents, is generally from eight to twelve years, and young persons are introduced into them with great formality and ceremony. Parents vie with each other in obtaining this honour for their children, and spare no cost on the occasion of their admission; the principal charge consisting in entertainments, and the customary presents to the Rhahaans. When a boy is to be introduced into a convent, either as a temporary resident, or with a view to future consecration, his friends prepare their offerings of cloth, rice, preserves, fruit, fans, cushions, mats, and household utensils. On an appointed day he parades the streets, dressed in yellow, and mounted on a horse richly caparisoned, led by two servants: a band of music goes before, and a party of Rhahaans encircle him: his male friends follow in a troop, and the females of their families bring up the rear, the latter carrying on their heads the offerings meant for the Rhahaans. Thus they proceed to the convent of which the novice is to become a member, where he is presented in form to the senior of the brotherhood. This ceremony is repeated three times, and at each perambulation, fresh presents are to be provided.

The Rhahaans, like the Carmelites, go barefooted, and have their heads close shaven, on which they never wear any covering. Yellow is the only colour worn by the priesthood; they have a long loose cloak, which they wrap round them, so as to cover most part of the body; they profess celibacy, and to abstain from every sensual indulgence. The prescribed punishment for a Rhahaan detected in an act of incontinence is, expulsion and public disgrace; the delinquent is seated on an ass, and his face daubed with black paint interspersed with spots of white; he is thus led through the streets, with a drum beating before him, and afterwards turned out of the city: but such instances of degradation are very rare. The juniors are restricted from wandering about licentiously, either by day or night. There is a prior in every convent, who has a discretionary power to grant permission to go abroad.

The Rhahaans never dress their own victuals, holding it an abuse of time to perform any of the common functions of life, which, so long as they occupy, must divert them from the abstract contemplation of the divine essence. They receive the contributions of the laity ready cooked, and prefer cold food to hot. At the dawn of the morning they begin to perambulate the town, to collect supplies for the day: each convent sends forth a certain number of its members,

who walk at a quick pace through the streets, supporting with the right arm a blue lackered box, in which the donations are deposited; these usually consist of boiled rice mixed with oil, dried and pickled fish, sweetmeats, fruit, &c. During their walk, they never cast their eyes to the right nor to the left, but keep them fixed on the ground; they do not stop to solicit, and seldom even look at the donors, who appear more desirous to bestow, than the others to receive. The Rhahaans eat but once a day, at the hour of noon. A much larger quantity of provision being commonly procured than suffices for the members of the convent, the surplus is disposed of, as charitably as it was given, to the needy stranger, or the poor scholars who daily attend them to be instructed in letters, and taught their moral and religious duties.

In the various commotions of the empire, colonel Symes says, that the Rhahaans take no active share, nor do they publicly interfere in politics, or engage in war: by this prudent conduct they excite no resentment: the Birmans and Peguers professing the same religion, the conquerors, to whichever party they belonged, equally respected the ministers of their faith. The head of the Rhahaans at Rangoon, called Seredaw, is treated with great veneration. He lives in a very handsome monastery half a mile from the town, on the road leading to Shoedagon, or temple. He is in no respect distinguished, as to his outward appearance, from the common Rhahaans. He goes every day, at the same hour, to the temple, to offer his devotions, and performs the journey, which is about four miles, on foot. In his conversation with Symes he betrayed a worldly pride inconsistent with his years (being about seventy-five) and sacred function: he announced, with much pomp, that he was the head of the church at Rangoon, and ostentatiously displayed, engraven on iron plates, his sacerdotal titles, which had been conferred on him by the present and the late king. Formerly there were nunneries of virgin priestesses, who, like the Rhahaans, wore yellow garments, cut off their hair, and devoted themselves to chastity and religion; but these were not long ago abolished, as being injurious to the population of the state. At present there are a few old women, who shave their heads, wear a white dress, follow funerals, and carry water to the convents; and these venerable dames are treated with some portion of respect. Symes's *Ava*, vol. ii.

**RHAIADAR**, or **RHAYADER**, in *Geography*, a borough and market-town in the cwmwd of Glynn-Jeithon, cantref of Maclenydd (now called the hundred of Rhayader), county of Radnor, South Wales, is situated on the banks of the river Wye, at the distance of 20 miles N.W. from New Radnor, and 176 W.N.W. from London. This place is a borough by prescription, and lays claim to a very high antiquity. It is governed by a bailiff, who is annually elected at a court-leet, held in the town-hall, at which also the burgesses are chosen by a town jury. Rhayader is one of the five contributory boroughs to return a representative to serve in parliament for the town of New Radnor. This place was formerly of much greater consequence and extent than at present. On Cefn-Ceido, about half a mile to the north-east, is a tract of land, called Pant-yr-Eglwys, where, according to tradition, a church anciently stood, which was included within the precincts of the borough. The great sessions for the county were at one time held here; and the county-court alternately met at New Radnor and Rhayader, till removed from the latter place to the town of Presteigne, in the reign of Henry VIII. The gaol for the security of criminals then stood on a spot of ground now occupied by a Presbyterian meeting-house; and the place of execution was at

at the north end of the town, near a house known by the appellation of Pen-y-Maes. At present Rhayader consists of four streets which intersect each other at right angles, and lie nearly parallel to the four cardinal points. In the wide space formed by the intersection of these streets stands the town-hall, which is a handsome building, rebuilt by subscription in 1762. The church is a plain structure, ornamented with a tower at one end; besides which there is a place of worship for Presbyterians and another for Methodists. The grammar-school was erected A.D. 1793, and has an endowment for the education of a limited number of poor children. The borough of Rhayader is a distinct parish of itself, and is exempt from the payment of county rates. The market-day here is Wednesday, weekly; and there are fairs on the 6th and 27th of August, 26th September, 14th October, and 3d December, for horses, sheep, and cattle; besides three great markets in May. The chief support of this town arises from the manufacture of woollens, principally flannel. According to the population returns of 1811, the parish contained 97 houses and 446 inhabitants.

On an eminence to the N.W. of the town stood the ancient castle of Rhayader, which was erected, in the year 1178, by Rhys-ap-Gruffydd, prince of South Wales, in order to check the incursions of the Normans, who, at that period, made great irruptions in the marches of Wales. In 1194, prince Rhys having been surprized and taken prisoner by his own sons, this castle was besieged and compelled to surrender to the sons of Cadwalhon-ap-Madawc of Maelienydd, by whom it was fortified for their own use. In the year 1231, after Llywelyn, prince of North Wales, had taken and destroyed the castle of Montgomery, he marched hither, and visited the castle of Rhayader with a similar fate. It was rebuilt, however, and continued to be a place of defence till the civil wars in the seventeenth century, when it was dismantled and totally destroyed; the fosse by which it was surrounded being the only vestige of it remaining at the present day. The tower, or citadel, stood in a direct line between the castle and the gaol, overlooking the river. The mount adjacent is still denominated Tower-hill. Near this place a stone bridge is thrown over the Wye, which the Welsh call Rhaiadr-Gwy, in allusion to the rumbling noise its impetuous waters make amidst the rocks. The only religious house, recorded to have been situated at Rhayader, was a convent of Dominican, or Black friars, founded soon after their first arrival in England, A. D. 1221. This house was suppressed in the 31st year of king Henry VIII.

In the immediate vicinity of Rhayader, the scenery of the Wye is peculiarly grand. Raging in its rocky bed, this river is seen through the light foliage of impendent trees, sometimes precipitating its waters over a bold ledge of rock, and sometimes searching its way among protruding crags, in a contracted sheet of glistening foam. The mountains by which the vale of Rhayader is environed, display a wild and rugged character, and are noted, according to local tradition, as being the place of shelter in which king Vortigern eluded the search of Hengist, after his alleged murder of the British nobles at Stonehenge. These hills abound with various kinds of minerals, particularly lead and copper. There are several cairns in this neighbourhood, the most remarkable of which is that of Tommen Sant Ffraid, on the S.W. side of the town, in the parish of Cwm-y-dan-Ddwr, supposed to be the cemetery of Saint Ffraid, the Popish tutelary saint of that parish. Carlisle's Topographical Dictionary of Wales, 4to. 1811. A Tour throughout South Wales and Monmouthshire, by J. T. Barber, F.S.A. 8vo. 1803.

RHAIDR, a river which rises in the E. part of Merio-

nethshire, North Wales, and runs into the Severn on the borders of Shropshire.

RHAIR, a considerable river of Hindoostan, which runs by the south side of Shawpour. The stream, which is about 100 yards wide and four feet in depth, dashes with great rapidity over a bed of rock; which prevents its being navigable for large boats. This river rises in the hills and forests of Surgooja, and after being joined by the Bijool and Gutain, falls into the Soane near Agowry.

RHAMNÆ, or RHANNÆ, in *Ancient Geography*, a people of India, in the mountains near the river Namadus. Ptolemy.

RHAMNI, in *Botany*, a natural order of plants in Jussieu, being the 95th in his series, or the 13th of his 14th class, and owing its name to the principal genus. See RHAMNUS.

See the character of the class under FICOIDÆÆ. The order is thus defined.

*Calyx* inferior, of one leaf, with a definite number of segments in the limb. *Petals* five, rarely four or six, and very rarely wanting, inserted into the upper part of the calyx, or into its disk, either opposite to, or alternate with, its segments, and equal to them in number; sometimes resembling little scales, and furnished with claws; sometimes united by their broad bases. *Stamens* of the same number as the petals, and inserted into the same part, either alternate with them, or opposite to them. *Germen* superior, encompassed below with the disk of the calyx. *Styles* either solitary, or of some definite number. *Stigmas* one or more. *Fruit* superior; in some instances pulpy, either with many cells, or many nuts, the cells, or nuts, single-seeded; in other cases capsular, of many cells and many valves, the partitions from the middle of each valve, and the cells containing either one or two seeds. *Coraculum* flat and straight, surrounded with a fleshy albumen. *Stem* arboreous or shrubby. *Leaves* either alternate or opposite, accompanied by *stipulas*, that are often very minute.

Section 1. *Stamens alternate with the petals. Fruit capsular. Staphylea; Euonymus; and Celastrus* of Linnæus; with *Polycardia* of Lamarck.

SECT. 2. *Stamens alternate with the petals. Fruit a drupe or berry.* Some genera of this section have the petals connected by their broad base.

*Myginda; Goupia* of Aublet, which is *Glossopetalum* of Schreber; *Rubentia* of Commerçon, certainly the same genus with Jacquin's *Elæodendrum*, as Jussieu indeed suspected; *Cassine; Schrebera* of Linnæus, a genus founded altogether in error, as we shall explain in its proper place; *Ilex; and Prinos.*

SECT. 3. *Stamens opposite to the petals. Fruit drupaceous.* *Mayepa* of Aublet, erroneously placed here, as belonging really to the *Jasmineæ* (see MAYEFEA); *Samara; Rhamnus; Ziziphus; Paliurus;* the two last separated from the Linnæan *Rhamnus*, by Jussieu. See PALIURUS.

SECT. 4. *Stamens opposite to the petals. Fruit three-lobed.* *Colletia* of Commerçon, Lamarck Illustr. t. 129; *Ceanothus; Hovenia; and Phyllia;* to which is to be added LASIOPETALUM; see that article.

SECT. 5. *Genera akin to Rhamni, their germen mostly superior.*

*Brunia* of Linnæus, some of whose reputed species have the germen superior, others inferior; and *Bumalda* of Thunberg.

SECT. 6. *Genera akin to Rhamni, but differing in having an inferior germen.*

*Gonania; Plethronia,* dubiously admissible here, as we have observed in its proper place; *Carpodetus* of Forster; *Aucubo*

*Aucuba* of Thunberg; and *Glossoma* of Schreber, which is Aublet's *Potomita*.

RHAMNOATZ, in *Geography*, a town of Sweden, in Wettmannland; 20 miles N. of Stroemholm.

RHAMNOIDES, in *Botany*, a name given by Tournefort, and others, to a genus of plants, called by Linnæus *bippophae*; which see.

RHAMNUS, in *Ancient Geography*, a borough of Attica, belonging to the Ajantide tribe, 60 stadia from Marathon, in a northerly direction from the Ægean sea, in a place where the land formed a small peninsula or Chersonesus. The houses were on the sea-coast; and upon an eminence was the temple of Nemesis, in which was a fine statue of the goddess, made by Phidias, of marble, which the Persians had brought from Paros for the purpose of forming a trophy, and which had been found in their camp after the battle of Marathon: the pedestal was adorned with four basso-relievos, representing different subjects of Grecian history. Leda is also exhibited presenting Helena to her mother Nemesis. See NEMESIS.

RHAMNUS, in *Botany*, so called by the ancient Romans, and by the Greeks *ῥαμνος*; words derived, according to De Theis, from the Celtic *Ram*, a head or tuft of branches, which is the origin of the Latin *ramus*, &c. and of the French *Rame*, *ramier*, &c.—Linn. *Gen.* 105. Schreb. 142. addend. 823. Willd. *Sp. Pl.* v. 1. 1092. Mart. Mill. *Dict.* v. 4. Sm. *Fl. Brit.* 261. Prodr. *Fl. Græc.* Sibth. v. 1. 157. Ait. *Hort. Kew.* v. 2. 14. Juss. 380. Lamarck *Illustr. t.* 128. Gært. *t.* 106.—Class and order, *Pentandria Monogynia*. Nat. Ord. *Dumose*, Linn. *Rhamnii*, Juss.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, urceolate; its limb in five spreading, acute, equal, coloured segments; the base permanent. *Cor.* Petals five, minute, between the segments of the calyx, opposite to the stamens, converging. *Stam.* Filaments as many as the petals, awl-shaped; anthers small. *Pist.* Germen roundish; style thread-shaped, equal to the stamens; stigma in various divisions. *Peric.* Berry roundish, naked, divided into fewer cells than there are segments of the calyx. Seeds solitary, roundish, gibbous on one side, compressed on the other.

Obs. We follow Jussieu and Schreber (in his addenda) in our denomination of the different parts of the flower, instead of taking the calyx for a corolla, with Linnæus. The genera of PALIURUS and ZIZIPHUS, separated from the original Linnæan *Rhamnus*, will be found in their proper places. *Fragula* and *Alaternus* of Tournefort have no just pretensions to be removed from the present genus.

Ess. Ch. Calyx urceolate. Petals five, opposite to the stamens. Berry superior.

We shall briefly define the species which authors have retained in *Rhamnus*, adding some new ones. The whole are shrubby, sometimes climbing. *Leaves* simple, undivided, stalked, veiny; mostly alternate. *Flowers* lateral, small, green or yellowish; sometimes with only four segments, petals and stamens, and in that case often dioecious, or polygamous, as in the first section.

Section 1. *Branches armed with terminal thorns.*

1. *R. catharticus*. Purging Buckthorn. Linn. *Sp. Pl.* 279. Willd. n. 1. *Fl. Brit.* n. 1. *Engl. Bot.* t. 1629. Woodv. *Med. Bot.* t. 114. *Fl. Dan.* t. 850. (*R. solutivus*; Ger. Em. 1337, with Clusius's figure of the following species. *Spina infectoria*; Matth. Valgr. v. 1. 143.)—Flowers four-cleft, polygamous. Leaves ovate. Stem erect. Berry with four seeds.—Native of woods and hedges throughout Europe, especially in moist situations. This is the white-thorn of the modern Greeks. A rigid bushy shrub, nearly smooth in every part; its branches terminating in strong thorns. *Leaves*

ferrated, with several lateral ribs. *Flowers* from the same buds as the leaves, yellowish-green, mostly, but not altogether, dioecious. *Stigma* four-cleft. *Berry* round, black, very purgative, when unripe affording a yellow dye.

2. *R. infectorius*. Turkey-berry Buckthorn, or Grain d'Avignon. Linn. *Mant.* 49. Willd. n. 2. Ait. n. 2. (*R. catharticus minor*; Arduin. *Mem.* 78. t. 14. *R. solutivus minor*; Ger. Em. 1337. *Spina infectoria pumila prima*; Clus. *Hist.* v. 1. 111.)—Flowers four-cleft, dioecious. Stem procumbent.—Native of the south of Europe. Frequent in rough stony places in Greece, and rightly considered by Dr. Sibthorp as the *Λυκων*, *Lycium*, of Dioscorides. The unripe berries are much used for dyeing, and imported in great quantities into England. They are what give the yellow colour to Turkey leather, or yellow morocco. This shrub is very nearly related to the first species, but grows procumbent, not erect, and the leaves are smaller and narrower. Gerard observes, that the segments of the calyx are but the length of the tube; not longer, as in *catharticus*; and that the stigmas are two, reflexed. *Fl. Gallopr.* 462. The stipulas are linear; not awl-shaped, as in the former; but we dare not rely on that circumstance, without further examination.

3. *R. lycioides*. Box-thorn Rhamnus. Linn. *Sp. Pl.* 279. Willd. n. 3. Ait. n. 3. Cavan.  *Ic.* v. 2. 66. t. 182. (*R. tertius*, forte niger Theophrasti; Clus. *Hist.* v. 1. 110. *R. tertius* Clusii; Ger. Em. 1334.)—Leaves nearly linear, obtuse, entire.—Native of Spain; frequent on the limestone hills of Valentia. Cavan. Differs widely from both the former in the narrow and entire leaves, tapering down into their slender footstalks.

4. *R. erythroxyton*. Red-wood Buckthorn. Pall. *Ross.* v. 1. p. 2. 26. t. 62, and t. 100. f. 8. Willd. n. 4.—Leaves linear-lanceolate, ferrated, rather acute.—Native of dry rocky places in Siberia.—The strongly ferrated and acute leaves distinguish this from the last. A variety with smaller, more finely ferrated, leaves, is Pallas's *R. lycioides*, t. 63.

5. *R. oleoides*. Olive-leaved Buckthorn. Linn. *Sp. Pl.* 279. Willd. n. 5. Ait. n. 4. (*R. secundus*; Clus. *Hist.* v. 1. 110. Ger. Em. 1334.)—Leaves obovate, entire; reticulated with veins beneath.—Native of Spain, *Afstroemer*; of Barbary, *Desfontaines*; of the southern part of Greece, and the island of Milo, *Sibthorp*. The shorter obovate leaves, copiously reticulated with veins, especially at the back, differ materially from those of *lycioides*. The fruit moreover has a much shorter stalk, though it is not so perfectly sessile as in Clusius's figure, which nevertheless we cannot hesitate to refer to this species.

6. *R. prunifolius*. Plum-leaved Buckthorn. Sm. *Prodr.* *Fl. Græc.* Sibth. n. 549. (*R. creticus*, amygdali folio minori; Tourn. *Cor.* 41.)—Stem procumbent. Flowers flat-tish, four-cleft, dioecious. Leaves obovate, obtuse, crenate, naked.—Found on the higher mountains of Crete.—Like the last in habit, but distinguished by its crenate, or somewhat ferrated, leaves. Stem depressed, or procumbent, with many entangled branches. The female flowers have occasional rudiments of stamens. Style cloven half way down. We find no figures referrible to this or the following.

7. *R. crenulatus*. Teneriffe Buckthorn. Ait. n. 5. Willd. n. 6.—Stem erect. Flowers three or four-cleft, dioecious. Leaves elliptic-oblong, bluntly ferrated, permanent.—Native of the Canary islands; *Maffon*. Brought in 1778 to Kew, where it blossoms in the greenhouse in March. A stout, erect, much-branched shrub. The leaves are finely reticulated beneath.

8. *R. saxatilis*. Rock Buckthorn. Jacq. *Austr.* t. 53. Linn. *Sp. Pl.* 1671. Willd. n. 7. Ait. n. 6. (*R. solu-*

tivus pumilus; Ger. Em. 1337. Spina infectoria pumila fecunda; Cluf. Hist. v. 1. 112.)—Stem spreading. Flowers four-cleft, dioecious. Leaves obovate, acute, serrated, deciduous.—Native of Auitria, Switzerland, Italy, and Greece. The rigid branched stems are more spreading or diffuse than those of *R. crenulatus*; the leaves deciduous, much less evidently reticulated. The flowers are pale yellow. Stigma in two deep acute divisions. Berries black.

9. *R. theezans*. Tea Buckthorn. Linn. Mant. 207. Willd. n. 8. (R. Thea; Osbeck's Travels, v. 1. 375.)—Leaves ovate, finely serrated; paler beneath. Flowers in terminal spikes, five-cleft.—Native of China.—A shrub six feet high, with long, roundish, downy, spreading branches; the lateral ones bearing hairy terminal spikes of flowers, and subsequently becoming spinous. Leaves an inch long, somewhat heart-shaped, beset with fine sharp serratures; shining and reticulated above; paler, opaque, and more even beneath. The poor people in China are said to use the leaves as a substitute for tea.

Sect. 2. Without thorns, or prickles.

10. *R. Sarcomphalus*. Timber Buckthorn. Linn. Sp. Pl. 280. Willd. n. 9. (Sarcomphalus; Browne Jam. 179.)—Leaves oval, coriaceous, emarginate, entire. Flowers in dense, corymbose, silky tufts.—Native of Jamaica. Browne says it is one of the best timber-woods in the island, and rises generally to a very considerable height. The trunk is often above two feet and a half in diameter, covered with a thick scaly bark. Wood hard, dark-coloured, close-grained. Leaves about three inches long, and two broad, smooth, with a strong mid-rib, and many interbranching veins. Browne's generic name applies to the thick, fleshy, umbilicated nectary, or receptacle of the flower. He describes no petals. The style is cloven, with two acute stigmas. Berry of two cells.

11. *R. ferreus*. Iron-wood Buckthorn. Vahl. Symb. v. 3. 41. t. 58. Willd. n. 10. Mart. n. 10.—“Leaves oblong-ovate, emarginate, membranous, smooth, entire. Flowers in axillary umbels.”—Native of the island of Santa Cruz; Von Rehr and West. Branches round, smooth, ash-coloured. Leaves an inch or more in length, very finely ribbed and veined. Umbels on short stalks. Vahl.

12. *R. levigatus*. Polished Buckthorn. Vahl. ibid. Willd. n. 11. Mart. n. 11.—“Leaves oblong, entire, coriaceous, smooth. Flowers axillary, about two together.”—Found in the same island. West. Branches round, smooth, ash-coloured. Leaves an inch and half long, paler and yellowish at the edges, especially the younger ones; scarcely veiny on the upper side; not at all so underneath. Flowers two or three together, on very short, simple, smooth stalks. Calyx smooth. Stigmas two. Vahl.

13. *R. tetragonus*. Square-branched Cape Buckthorn. Linn. Suppl. 153. Willd. n. 12. Thunb. Prodr. 44.—“Leaves ovate, entire, smooth, sessile. Branches square.”—Gathered by Thunberg, at the Cape of Good Hope. We have seen no specimen, nor is there any figure of this species.

14. *R. polifolius*. Poley-leaved Buckthorn. Vahl. Symb. v. 3. 41. Willd. n. 13.—Leaves lanceolate, entire; snow-white and downy beneath. Flowers axillary, nearly sessile, mostly solitary.—Supposed to be a native of New Zealand. Branches slender, hoary; downy when young. Leaves hardly an inch long, pointed; smooth and somewhat wrinkled above. Footstalks very short, downy.

15. *R. valentinus*. Valencia Buckthorn. Willd. n. 14. (R. pumilus; Cavan. Ic. v. 2. 65. t. 181.)—Leaves roundish-elliptical, minutely crenate, nearly sessile. Flowers four-cleft. Style deeply three-cleft. Berry dry.—Gathered

by Cavanilles, on the mountains of Meca and Palomera, in the kingdom of Valentia, flowering in May. If he be correct as to the nature of the fruit, this is a very distinct species; otherwise its habit is very like *pumilus* hereafter described. The stems are short and depressed. Leaves on very short stalks, and obscurely crenate. Flowers hermaphrodite, four-cleft. Style divided to the base into three parts. Capsule, or dry berry, of three cells.

16. *R. cubensis*. Cuba Buckthorn. Linn. Sp. Pl. 281. Willd. n. 15. Jacq. Hort. Vind. v. 3. 28. t. 49.—“Leaves rugose, entire, downy. Flowers hermaphrodite. Capsule of three cells.”—Native of bushy places near the sea, in the island of Cuba. We have not examined any specimen, but by Jacquin's account, this appears rather to have the fruit of a *Ceanothus*. The petals indeed are opposite to the stamens, which is an important character of *Rhamnus*. The fruit however is not a dry berry, but a true capsule, with elastic valves.

17. *R. colubrinus*. Bahama Red-wood Buckthorn. Linn. Sp. Pl. 280. Willd. n. 16. Ait. n. 7. Jacq. Hort. Vind. v. 3. 28. t. 50. (Arbor baccifera indica, foliis majoribus splendentibus, flore pentapetalo; Comm. Hort. v. 1. 175. t. 90.)—Leaves ovate, entire, with rusty footstalks. Flowers monogynous, erect. Capsules three-lobed.—Native of the Bahama islands; introduced into our stores by Cateby, in 1726. This has also the fruit of *Ceanothus*, to which genus Miller refers it.

18. *R. dauricus*. Daurian Buckthorn. Pall. Rofs. v. 1. p. 2. 25. t. 61, catharticus. Willd. n. 17. (Cornus foliis citri angustioribus; Amman. Ruth. 200. t. 33.)—Leaves ovate, serrated, veiny; tapering at the base. Flowers four-cleft, dioecious.—Found by Gmelin and Pallas on the banks of the river Argunus in Dauria. The wood is red, and called Sandal-wood by the Russians. The aspect of the shrub is much like *R. catharticus*, but there are no thorns. Pallas's names, pages, and references are wonderfully confused in this, and too many other, parts of his pompous book.

19. *R. alpinus*. Alpine Buckthorn. Linn. Sp. Pl. 280. Willd. n. 18. Ait. n. 8. (R. n. 823; Hall. Hist. v. 1. 366. t. 40. Frangula ora folii serrata; Hall. Enum. 164. Alnus nigra baccifera, rugosiore folio, seu major; Baul. Hist. v. 1. 562. Creutzbeer; Lonc. Kreuterb. 59?)—Stem erect. Leaves elliptic-oblong, with glandular crenatures; somewhat heart-shaped at the base; veins hairy at the back. Flowers dioecious. Stigma four-cleft.—Native of the alps of Switzerland, Dauphiny, Austria, Carniola, &c. Gathered probably by Dr. Sibthorp on mount Parnassus; see n. 21. A shrub, eight or ten feet high, erect, with a smooth grey bark. Leaves two inches or more in length, broadly elliptical, occasionally obtuse or acute; more or less heart-shaped at the base: finely and regularly crenate throughout, with rounded glandular teeth; smooth, except that the numerous straight parallel veins are hairy beneath, especially at their origin. Flowers copious, axillary, stalked, four-cleft, dioecious. Stigma in four narrow deep segments. Berry black, of three cells, with mostly a seed in each. The female flowers have the rudiment of a style, according to Wulfen in Jacq. Coll. v. 3. 16, but the shrub is nevertheless perfectly dioecious.

20. *R. pumilus*. Dwarf Rock Buckthorn. Linn. Mant. 49. Willd. n. 19. Ait. n. 9. Jacq. Coll. v. 2. 141. t. 11. (R. rupestris; Scop. Carn. v. 1. 164. t. 5, bad. Villars Dauph. v. 2. 538.)—Stem prostrate. Leaves somewhat obovate, crenate, smooth on both sides. Stigma three-cleft.—Native of mount Baldus, and the alps of Dauphiny and Carniola. We have gathered it on mount Cenis. This is a small depressed shrub, creeping close to the rocks. The

leaves

leaves are smaller than the last, with broader less numerous crenatures, and we find them also tapering constantly at the base, not inclined to be heart-shaped, as Scopoli and Wulfen (in Jacquin), both represent them. The latter erroneously describes and delineates a simple capitate stigma; in our specimens, and those of Villars, that part is deeply three-cleft. We see no reason to believe the *pumilus* of this last author distinct from his *rupestris*. The flowers of our *pumilus* are described, by most writers, as having all perfect stamens and pistils, but Villars says they appeared to him dioecious.

21. *R. pubescens*. Downy Mountain Buckthorn. Sm. Prodr. Fl. Græc. Sibth. n. 552. Fl. Græc. t. 239, unpublished.—Leaves obovate-rhomboid, villous, nearly entire. Flowers dioecious. Style deeply divided.—Gathered by Dr. Sibthorp on mount Parnassus. This is a knotty, zigzag, spreading, not very upright, shrub, vying in magnitude with *R. alpinus*, for which possibly Dr. Sibthorp might at one time have taken it, when he made a memorandum of *alpinus* being found on Parnassus; as we observe no specimen in his collection to confirm such memorandum. It is, nevertheless, extremely probable that both species may grow there. The present is very distinct from *alpinus* in having downy, and nearly entire leaves. The flower-stalks and calyx are also downy. Petals roundish, concave, found in the male flowers only. Female flowers on a separate plant. Style divided nearly to the base, with only two stigmas. This species is more akin to the following than to any of the foregoing.

22. *R. Frangula*. Alder Buckthorn, or Berry-bearing Alder. Linn. Sp. Pl. 280. Willd. n. 20. Fl. Brit. n. 2. Engl. Bot. t. 250. Fl. Dan. t. 278. (*Frangula*; Camer. Epit. 978. Matth. Valgr. v. 2. 609. *Alnus nigra*, five *Frangula*; Ger. Em. 1470.)—Leaves obovate, entire, smooth. Style simple, very short. Stigma cloven.—Native of bushy places in the north of Europe more especially, though Dr. Sibthorp observed it about Constantinople. It flowers, like most of the species of *Rhamnus*, in the spring. The stem is shrubby, about four feet high. Leaves two or three inches long and about one broad, somewhat pointed. Flowers whitish, with very minute petals and stamens, in the same individuals with the pistils. Style very short, with two small segments to the stigma. Berry black, roundish, with seldom more than two seeds, though we have seen three, in which case, we presume, there must have been a three-cleft stigma. These berries are sometimes mixed, by herb gatherers, with those of the true Buckthorn, n. 1, or substituted for those berries; but the smaller number of seeds betrays the deception. Their qualities perhaps differ very little.

23. *R. latifolius*. Broad-leaved Azorian Buckthorn. L'Herit. Sert. Angl. 5. t. 8. Willd. n. 21. Ait. n. 11.—Leaves elliptical, pointed, entire. Calyx hairy. Style simple.—Gathered by Mr. Masson in the Azores. He sent it to Kew in 1778, and it blossoms there in July, being kept in winter under cover. This is a tall upright shrub, with round, straight, smooth branches. Leaves four or five inches long, and two broad; smooth above; paler with hairy ribs, beneath. Flowers hairy, axillary, many together, on hairy rusty stalks. Petals broad at the base. Stigma slightly three-cleft.

24. *R. glandulosus*. Madeira Buckthorn. Ait. n. 12. Willd. n. 22. Venten. Malmaif. t. 34.—Leaves ovate, bluntly serrated, smooth; glandular at the base. Stem erect. Flowers racemose. Style in three deep segments.—Native of Madeira, and the Canary islands. Introduced at Kew, by Mr. Masson, in 1785. This has the habit of an *Ilex* or *Phillyrea*. The leaves are dark green, smooth, two inches long, more or less, ovate, pointed, rather distantly

serrated, marked on the upper side, near the base, with two or three glandular spots. Flowers yellowish, numerous, on smooth, racemose axillary stalks. Stamens twice as long as the petals. Style deeply three-cleft. Stigmas simple. We know nothing of the fruit.

25. *R. ellipticus*. Oval-leaved Jamaica Buckthorn. Ait. n. 13. Willd. n. 23. Swartz Ind. Occ. v. 1. 497. (R. n. 1; Browne Jam. 172. t. 29. f. 2. *Ceanothus reclinatus*; L'Herit. Sert. Angl. 6.)—Leaves elliptical, acute, entire; rather villous beneath. Flowers axillary, somewhat umbellate. Style in three deep segments. Berry dry.—Native of bushy places on the mountains of Jamaica. Miller cultivated it in the stove at Chelsea in 1758. Aiton. Stem forming a small tree, with spreading or dependent branches. Leaves two or three inches long, thin, downy on the veins beneath. Flowers greenish-white. The fruit seems, by Swartz's description, a dry berry, like that of some other species of *Rhamnus*, and not the valvular capsule of a *Ceanothus*, though, when quite ripe and dried, it splits into six parts, as we find it in Browne's specimen. The petals however are opposite to the stamens.

26. *R. prinoides*. Winter-berry-leaved Buckthorn. L'Herit. Sert. Angl. 6. t. 9. Willd. n. 24. Ait. n. 14. (R. celtifolius; Thunb. Prodr. 44. *Celtis foliis subrotundis dentatis, flore viridi, fructu luteo*; Burm. Afr. 242. t. 88.)—Leaves ovate, serrated, smooth. Stem erect. Flower-stalks simple. Style slightly three-cleft. Flowers polygamous.—Native of woods at the Cape of Good Hope, where it blossoms in September; as is the case in England, where this shrub was first cultivated by Robert Edward, lord Petre. Its habit is that of a *Prinos*, or *Phillyrea*. The leaves are from one to two inches long, pointed; shining above; paler beneath; smooth, except occasional hairiness at the origin of each vein. Flowers on simple, slender, axillary stalks, several together. Petals narrow. This species, except in its inflorescence, and the want of glands on the leaves, bears a considerable resemblance to the *glandulosus*.

27. *R. mystacinus*. Wiry Buckthorn. Ait. n. 15. Willd. n. 25.—Leaves heart-shaped, entire. Stem climbing with tendrils. Flowers in axillary umbels. Stigma three-cleft.—Said to be a native of Abyssinia; at least it was brought to Kew, in 1775, by the celebrated traveller Mr. Bruce. It is kept in the stove, and blooms in November. The stem is weak, climbing to a considerable extent, by means of simple solitary axillary tendrils from the upper part of the branches. Leaves an inch long, rather downy beneath, obtuse with a small point, on very short footstalks. Flowers greenish-white. Germs immersed in a snow-white glandular receptacle, filling the tube of the calyx. As nothing is known of the fruit, this plant may possibly prove of the genus *Zizyphus*, to which it seems most akin in habit.

28. *R. alnifolius*. Alder-leaved American Buckthorn. L'Herit. Sert. Angl. 5. Willd. n. 26. Ait. n. 16.—Leaves obovate, pointed, serrated, smoothish, opaque; reticulated beneath. Flowers hermaphrodite. Stem erect.—Native of Pennsylvania, from whence we have a specimen, communicated by the Rev. Dr. Muhlenberg. It has much the aspect of *R. alpinus*, but the leaves, as L'Heritier observes, are less shining, and more reticulated; they seem to us more tapering at the base, and not at all heart-shaped.

29. *R. sphaerospermus*. Clear-berried Buckthorn. Swartz Ind. Occ. v. 1. 499. Willd. n. 27.—Leaves oblong, serrated, smooth. Stem erect. Flowers in axillary clusters. Style three-cleft. Berry nearly globular, pellucid.—Native of bushy hills in the more temperate parts of Jamaica, flowering in August.—A small tree, ten to fifteen feet high, with

## RHAMNUS.

spreading branches. Leaves pointed, finely veined. Clusters many-flowered, the length of the footstalks. Flowers small, yellowish-green. Style very short. Berry the size of a small pepper-corn, either quite globular, or obscurely three-lobed, pellucid, pale green, with one or three seeds. It ripens in October.

30. *R. hybridus*. Mule Buckthorn. L'Herit. Sert. Angl. 5. Willd. n. 28.—“Leaves oblong, pointed, serrated, scarcely perennial. Stem erect. Flowers male and female on the same tree.”—L'Heritier describes this as having sprung up in a garden, from seeds of *R. alpinus* impregnated by *R. alaternus*, and partaking of the nature of both parents.

31. *R. Alaternus*. Common Alaternus. Linn. Sp. Pl. 281. Willd. n. 29. Ait. n. 17. (Alaternus 1 et 2; Clu. Hist. v. 1. 50. Ger. Em. 1398.)—Leaves ovate, serrated, coriaceous, smooth. Stem erect. Flowers dioecious, in axillary, somewhat compound, bracteated clusters. Stigma in three deep segments.—Native of the south of Europe. A hardy evergreen shrub in our gardens, flowering in the spring. The leaves are about an inch long, of a shining yellowish-green, and of a thick rigid texture. Flowers copious, yellowish. Berries dark purple, with two or three seeds.

The 30th species of Willdenow, *R. carpinifolius*, adopted from Pallas's Fl. Ross. t. 60, is, we believe, the same tree with *Ulmus nemoralis*, Willd. Sp. Pl. v. 1. 1326, or at least of the same genus. See ULMUS.

SECT. 3. Branches armed with prickles.

32. *R. capensis*. Prickly Cape Buckthorn. Thunb. Prodr. 44. Willd. n. 31.—“Prickles solitary. Leaves ovate, notched or entire, smooth. Umbels axillary.”—Found by Thunberg, at the Cape.

33. *R. circumscissus*. Prickly East-Indian Buckthorn. Linn. Suppl. 152. Willd. n. 32.—Prickles solitary, hooked. Leaves obovate, abrupt, emarginate, entire, smooth. Umbels axillary.—Found by Koenig, in the East Indies. Branches angular. Prickles numerous, strong. Leaves almost an inch long, and nearly as broad. Umbels many-flowered. Style simple, short, permanent. Base of the calyx cup-like after the limb is fallen.

RHAMNUS, in Gardening, furnishes plants of the tree and shrub kinds, of which the species cultivated are; the purging buckthorn (*R. catharticus*); the pubescent rhamnus, or buckthorn redwood (*R. colubrinus*); the alder buckthorn, or berry-bearing alder (*R. frangula*); the common Christ's-thorn (*R. paliurus*); the common alaternus (*R. alaternus*); the blunt-leaved buckthorn (*R. jujuba*); the pointed-leaved buckthorn (*R. œnoplia*); the shining-leaved buckthorn, or common jujube (*R. zizyphus*); and the Syrian Christ's-thorn (*R. spina Christi*).

It is found that the juice of the unripe berries, in the first sort, has the colour of saffron, and is used for staining maps or paper, being sold under the name of French berries: the juice of the ripe berries, mixed with alum, is the sap-green of the painters; but if the berries be gathered late in the autumn, the juice is purple. The bark affords a beautiful yellow dye.

In the third sort, the berries gathered before they are ripe, dye wool green and yellow; when ripe, blue-grey, blue, and green. The bark dyes yellow, and with preparations of iron, black.

There are two varieties of this sort, the broad-leaved, which has larger and rougher leaves; it grows naturally on the Alps: and the dwarf or round-leaved, which is of humble growth, seldom rising above two feet high; it grows on the Pyrenees.

The fifth is a native of the south of Europe, and of Bar-

bary. The fresh branches or young shoots, with the leaves, will dye wool a fine yellow. It flowers about April. And there are varieties with variegated leaves, commonly called bloated phillyrea by the nurserymen; and with the leaves striped with white and with yellow, called silver and gold-striped alaternus. The latter has the leaves much longer and narrower, and the serratures on the edges much deeper: this shoots its branches more erect, forms a handfomer bush, and is equally hardy. It is likewise observed, that the phillyrea is sometimes different; and according to some, there are also the large-growing, the small-growing, the broad-leaved, the narrow-jagged-leaved, the yellow-striped jagged-leaved, the white-striped jagged-leaved: all which are confounded with the alaternus, by such persons as are not botanists; but they may easily be distinguished by the position of their leaves, which are alternate in this, but placed opposite by pairs in that. And it is supposed, that the alaternus was much more in request formerly than at present, having been planted against walls in court-yards to cover them, as also to form evergreen hedges in gardens; for which purpose it is very improper, as the branches shoot very vigorously, and being pliant, are frequently displaced by the wind; in winter, when much snow falls in still weather, the weight of it often breaks the branches; these hedges must also be clipped three times in a season to keep them in order, which is both expensive and occasions a great litter in a garden.

The fruit, in the eighth sort, is sold in the market at Canton during the autumn. In Italy and Spain it is served up at the table in deserts during the winter season, as a dry sweetmeat.

And the common or cultivated jujube, according to Miller, has a woody stalk, dividing into many crooked irregular branches, armed with strong straight thorns, set by pairs at each joint; the leaves are two inches long and one broad, slightly serrate, on short footstalks; the flowers are produced on the side of the branches, two or three from the same place, sessile, small and yellow: the fruit oval, the size of a middling plum, sweetish and clammy, including a hard oblong stone, pointed at both ends.

The wild jujube has slender woody stalks, which send out many weak branches, covered with a greyish bark, and armed with spines in pairs, one longer and straight, the other short and recurved; the leaves small, oval, veined, half an inch in length and breadth, and sessile. It is found about Tunis in Africa.

*Method of Culture.*—The first, third, and fourth sorts may be increased by seeds, layers, and sometimes by cuttings; the seeds should be sown in autumn as soon as ripe, on a bed of light earth, and slightly raked in: the plants mostly appear in the following spring, and when they have had a year or two's growth, they should be planted out in nursery-rows, to have two or three years more growth, when they may be finally set out where they are to stand.

It may be noticed that the layers should always be made from the young shoots, and be laid down in the autumn, in the usual way, giving a little twist or nick at the time in the bark, at a joint. They mostly become well rooted in twelve months afterwards.

Cuttings of the first and third sorts may be made from the young twigs, and be planted in rows in the autumn, in a bed of good earth, when most of them will succeed and grow well.

And all the evergreen or alaternus kinds may be raised from seeds and by layers. The plain sorts succeed in both methods, but the variegated sorts only with certainty by layers, well laid down.

And

And the seeds should be put into the ground in the early autumn in the same manner as above; and the layers laid down in the autumn as in the other kinds of plants.

All the other species may be raised by sowing the stones of the fruit in pots in spring, plunging them in a moderate hot-bed. When the plants have attained some growth they should be removed into separate pots, and be managed as other tender plants. They also succeed by suckers from the roots and layers, as in the above sorts. And the sixth and eighth sorts may be placed in the greenhouse, and the others in the stove.

These are all ornamental plants; the hardy sorts for the pleasure-ground, and the more tender sorts for the greenhouse and stove, among other potted plants of these departments.

*RHAMNUS catharticus*, or *spina cervina*, purging buckthorn, in the *Materia Medica*. The fruit or berries of this shrub, which have been long received into the materia medica, are about the size of a small pea, and, when ripe, of a shining black colour; they contain a pulpy deep green juice, called by the French "verd de vessie," or *Sap-green* (which see), which has a faint unpleasant smell, and a bitterish, acrid, nauseous taste; they operate briskly by stool, and hence the plant derives the trivial name "catharticus;" their purgative effects are constantly accompanied with considerable thirst, and dryness of the mouth and throat, and frequently with severe griping of the bowels, especially unless some diluting liquor be plentifully drunk immediately after taking them. The dose is said to be about 20 of the fresh berries in substance; twice or thrice that number in decoction; a drachm or a drachm and a half of the dried berries; an ounce of the expressed juice; or half an ounce of the rob or extract, obtained by inspissating the juice. The juice made into a syrup is the officinal preparation, and in this state it has been generally preferred by physicians, who found that in doses of one ounce or two it proved a very powerful purgative; and was therefore much employed as a hydragogue. Few patients, however, are able to bear a frequent repetition of this medicine; and even Sydenham, who was partial to the purgative treatment of hydropical diseases, found that other cathartics more effectually answered this purpose. At present it is rarely preferred, except in conjunction with other medicines of this class. Lewis's Mat. Med. Woodville's Med. Bot.

*RHAMNUSIA*, in *Mythology*, an appellation given to Nemesis, on account of her celebrated statue at Rhamnus, in Attica, which has been generally ascribed to Phidias. Pliny, however, gives the honour of it to Ageracritus, a scholar of Phidias, who, as he says, had designed it for a Venus; but seeing one preferred to it, which was executed by Alcamenes, another scholar of the same matter, sold his to the Rhamnusians, on condition that they would only take it for a statue of Nemesis, whence she gained the name of Rhamnusia. See *NEMESIS* and *RHAMNUS*.

*RHANDÆ*, in *Ancient Geography*, a people of Asia, in Drangiana, on the confines of Asia. Ptolemy.

*RHANTERIUM*, in *Botany*, so named by Desfontaines, from *ῥαντινόν*, a kind of brush for sprinkling water, like that used in Catholic churches; the down, or crown, of the seed having a similar form.—Desfont. Atlant. v. 2. 291. Willd. Sp. Pl. v. 3. 2105.—Class and order, *Syn-genesia Polygamia-superflua*. Nat. Ord. *Compositæ discoidæa*, Linn. *Corymbifera*, Juss.

Gen. Ch. *Common Calyx* imbricated, nearly cylindrical; scales lax, recurved. *Cor.* compound, radiated; florets of the disk numerous, equal, funnel-shaped, five-cleft, erect, all perfect; those of the radius few, ligulate, three-toothed, recurved, female. *Stam.* in the perfect florets five, awl-

shaped, short; anthers simple, united into a five-toothed cylinder. *Pist.* Germen in all the florets inversely conical, furrowed; style thread-shaped, the length of the stamens; stigmas two, club-shaped. *Peric.* none, except the permanent calyx. *Seeds* of all the florets the shape of the germen; those of the disk crowned with from four to six bristles, thickened and feathery at the top; those of the radius naked. *Recept.* flat, chaffy; scales acute, hollowed on one side.

Eff. Ch. Receptacle chaffy. Seed-down of about five bristles, feathery at the top. Calyx cylindrical, imbricated. Seeds of the radius naked.

1. *R. sarsureolens*. Desfont. Atlant. v. 2. 291. t. 240.—Found by Desfontaines on the sandy sea-coast, near Sfax, in the kingdom of Tunis. *Root* perennial. *Stem* erect, much branched, round, leafy, one or two feet high. *Branches* slender, downy, striated, often entangled together. *Leaves* scattered, sessile, three quarters of an inch long, lanceolate, acute, strongly serrated, either smooth or downy; the upper ones smaller, linear and entire. *Flowers* terminal, solitary, resembling those of several of the smaller-flowered American Asters, except in being entirely yellow. This plant flowers in summer. The bruised leaves have a fragrant smell.

*RHAPHANÆ*, in *Ancient Geography*, a town of Asia, in Syria, placed by Ptolemy between Epiphania and Anteradus.

*RHAPHIS*, in *Botany*, so called from *ῥαπίς*, a needle, or awl, because of the long needle-like awn of the female flowers.—Lour. Cochinch. 552.—Class and order, *Monocæcia Triandria*. Nat. Ord. *Gramina*.

Gen. Ch. Male flowers two, stalked, in one common involucre. *Cal.* Glume single-flowered, of two awl-shaped, coloured, beardless, nearly equal valves. *Cor.* Glume of two lanceolate, membranous, fringed, beardless valves, shorter than the calyx. *Stam.* Filaments three, short; anthers oblong.

Female flower solitary, in the same sort, one-leaved, hairy involucre, sessile, below the male flowers. *Cal.* as in the male, but shorter. *Cor.* Glume of two valves, nearly equal to the calyx; one of them furnished with a longish, very sharp awn. *Pist.* Germen ovate; styles two, short; stigmas feathery. *Peric.* none, except the permanent glumes. *Seed* solitary, oblong, compressed.

Eff. Ch. Involucre of one leaf, three-flowered. Male, Calyx of two valves, coloured. Corolla of two fringed valves.

Female, Calyx like the male. Corolla of two valves: one of them awned. Styles two. Seed one, oblong.

1. *R. trivialis*. (*Gramen aciculatum*, Cusu Cusu; Rumph. Amboin. v. 6. book 10. chap. 8. t. 5. f. 1. Co may of the Cochinchinese.)—A very common grass in China and Cochinchina, growing by road sides, and proving very troublesome on account of its seeds, which stick into the clothes of passengers, and cannot be shaken out. Rumphius speaks of it as equally common in the islands of the East Indies. The root is annual, creeping. *Stem* a foot high, erect, round, slender, smooth, scarcely branched, almost leafless, except at the base. *Leaves* nearly all radical, sessile, short, lanceolate, clasping the lower part of the stem. *Panicle* simple, solitary, terminal, conical, lax; its branches long, straight, ascending. Linnæus erroneously cites the above synonym of Rumphius, under his *Panicum colonum*, a widely different plant.

Mr. Brown, in Prodr. Nov. Holl. v. 1. 199, suggests that the above plant of Lourcuro and Rumphius ought to be referred

referred to the genus *Holcus*, along with all the paniced species of *Andropogon*; and he remarks, on the authority of a specimen from the author, in Sir J. Banks's collection, that it seems scarcely distinct from *Andropogon acicularis* of Retzius, Willd. Sp. Pl. v. 4. 906, for which indeed the same synonymy of Rumphius is quoted.

RHAPIS, so called by the younger Linnæus, from  $\rho\acute{\alpha}\pi\iota\varsigma$ , a rod, probably in allusion to the name it has obtained from Europeans in China, of Ground Ratan; but we know not precisely how that name applies to the plant.—Ait. Hort. Kew. ed. 1. v. 3. 473. ed. 2. v. 5. 473. Schreb. 772. Willd. Sp. Pl. v. 4. 1093. Mart. Mill Dict. v. 4.—Class and order, *Polygamia Monocia*; rather *Hexandria Monogynia*. Nat. Ord. *Palma*.

Gen. Ch. Cal. Perianth inferior, minute, rigid, of one leaf, in three deep, broad, concave, permanent segments. Cor. of one petal, larger than the calyx, in three deep, erect, concave, equal segments, deciduous. Stam. Filaments six, awl-shaped, nearly as long as the corolla; anthers roundish, two-lobed. Pist. Germen superior, three-lobed; style short, awl-shaped; stigma obtuse. Peric. Berry roundish-ovate. Seed solitary, roundish, bony.

Obf. The flowers are often polygamous or dioecious.

Ess. Ch. Calyx three-cleft. Corolla of one petal, three-cleft. Berry with one large, roundish, bony seed.

1. *R. flabelliformis*. Creeping-rooted Palmetto, or Ground Ratan. Ait. n. 1. Willd. n. 1. Sm. Tour, v. 1. 12. and 279. Jacq. Hort. Schœnbr. v. 3. 36. t. 316. Curt. Mag. t. 1371. (*Chamærops excelsa*; Thunb. Jap. 130.)—Leaves palmate, plaited; their plaits and margins sharply toothed.—Native of China and Japan. Root creeping, with numerous long straight fibres. Stem rising to a great height in its native country; in our stoves it has not yet reached above six or eight feet; it is clothed with a loose network, formed of the bases of the decayed leaf-stalks. Leaves stalked, divided almost to the base into many plaited oblong lobes, a span long, rough at the ribs and edges with prickly teeth. Flowers mostly dioecious, yellow, in paniced cylindrical spikes. Berry small, dark purple, sweet with a bitterish flavour, barely eatable.

2. *R. aculis*. Swamp Palmetto. Willd. n. 2. Ait. n. 2. (*Corypha minor*; Jacq. Hort. Vind. v. 3. 8. t. 8. Sabal Adanioni; Gawl. in Curt. Mag. t. 1434. Pursh v. 1. 239.)—Leaves palmate, striated, entire, smooth.—Native of the sea-coast of Carolina and Georgia, flowering in August. Of humble growth, having no leafy stem. The leaves are longer and narrower than in the foregoing, quite smooth and entire. Flowers numerous, greenish-white, in numerous, cylindrical, lax, paniced spikes, supported by a straight, round common stalk, taller than the foliage. Berry the size of a small pea, black, sweetish. Jacq.

3. *R. arundinacea*. Simple-leaved Palmetto. Ait. n. 3. Willd. n. 3.—Leaves in two deep, acute, plaited lobes; roughish at the edges.—Native of Carolina. A green-house plant at Kew, flowering in September.

The orthography of the generic name in Curt. Mag. 1434, is remarkably confused, and seems to have misled Mr. Pursh to print it *Raphis*, citing Willdenow without examination.

RHAPONTICUM. See RHIA.

RHAPONTICUM, a medicinal root, in form resembling rhubarb, and nearly of the same virtues.

It was called *rhaponticum*, q. d. *root of Pontus*; because chiefly produced in the country of Pontus in Asia.

It is the root of a plant, which is a species of the *rheum*, with smooth roundish leaves, and somewhat channelled pedicles. It grows wild on the mountain Rhodope in Thrace,

from whence it was brought into Europe by Alpinus about the year 1610; it bears the hardest winters of this climate. The root of this plant, says Dr. Lewis, which appears to have been the true rhubarb of the ancients, is confounded by some with the modern rhubarb, though considerably different from that root in appearance, as well as in quality. The rhapontic is of a dusky colour on the surface, and of a loose spongy texture; more astringent than rhubarb, and less purgative: in this last intention, two or three drachms are required for a dose. Lewis's Mat. Med.

It has, however, been much controverted, whether the rhaponticum of the ancients, and the rhubarb of the moderns, be one and the same plant: the reasoning on both sides may be seen in the appendix to the second volume of John Bauhin's History of Plants. See RHUBARB.

RHAPPHA, in *Ancient Geography*, a town of India, on the other side of the Ganges, among the people called Gangani. Ptolemy.

RHAPSA, a town of Asia, in the interior of Media.

RHAPSODI,  $\rho\acute{\alpha}\psi\omicron\delta\omicron\iota$ , RHAPSODISTS, in *Antiquity*, persons who made a business of singing or reciting pieces of Homer's poems.

Cuper informs us, that the rhapsodi were clothed in red, when they sung the Iliad; and in blue, when they sung the Odyssey.

They performed on the theatres; and sometimes strove for prizes, in contests of poetry, singing, &c.

After the two antagonists had finished their parts, the two pieces, or papers they were written in, were joined together again; whence the name, *viz.* from  $\rho\acute{\alpha}\psi\tau\alpha$ , *suo*, I join together, and  $\omega\delta\omicron\varsigma$ , *ode*, song.

But there seem to have been other rhapsodi of higher antiquity than these; people who composed heroic poems, or songs in praise of heroes and great men, and sung their own compositions from town to town, for a livelihood; of which profession, it is said, was Homer himself.

Hence, some critics, instead of the former origin, derive the word rhapsodist from  $\rho\acute{\alpha}\psi\delta\omicron\upsilon$   $\alpha\delta\omicron\upsilon\varsigma$ , to sing with a laurel-rod in the hand, which, it seems, was the badge of the primitive rhapsodi.

Philochorus, again, derives the word from  $\rho\acute{\alpha}\psi\tau\epsilon\upsilon$   $\tau\alpha\varsigma$   $\omega\delta\omicron\alpha\varsigma$ , q. d. *συνθέσειν*, to compose songs or poems; as if they were the authors of the poems they sung. This opinion, to which Scaliger inclines, reduces these rhapsodi to the second kind.

In effect, it is probable, that they were all of the same class, whatever distinction some authors may imagine among them; and that their business was to sing or rehearse poems, either of their own, or other people's composition, as might best serve their purpose, which was gaining a pecuniary advantage by them. So that we do not apprehend it any injury to them, to set them on the foot of our ballad-singers; some of whom may probably pen their own ditties. After Homer's time, it is no wonder they confined themselves altogether to his pieces, for which the people had the utmost veneration; nor is it surprising, that they should erect stages, &c. and dispute the point of recitation in fairs and markets.

The import of the word rhapsodist underwent several changes in antiquity: it was first appropriated to bards, who sung their own verses from town to town, or at the tables of the great; in this sense Homer was called a rhapsodist. It was next bestowed on those who sung the verses of Homer on the stage, usually for a prize, allotted to the best performer of them; and, lastly, to such singers of centos, as have been just described. A rhapsody, in modern language, conveys no other meaning than that of an incoherent

incoherent jumble of ideas. This sense of the word undoubtedly took its rise from the notorious folly and absurdity of the rhapsodists, in their rapturous comments upon their favourite poets; for they undertook to explain, as well as to recite. Hence it is that in Suidas, the word *ῥαψωδία* is defined by *ἄλογος, nonsense*.

**RHAPSODOMANCY**, *ῥαψωδομαντεία*, an ancient kind of divination performed by fixing on a passage of a poet at hazard, and reckoning on it as a prediction of what was to come to pass.

There were various methods of practising this rhapsodomancy. Sometimes they wrote several verses or sentences of a poet on so many pieces of wood, paper, or the like; shook them together in an urn; and drew out one, which was accounted the lot.

Sometimes they call dice on a table, on which verses were written; and that on which the die lodged, contained the prediction.

A third manner was by opening a book, and pitching on some verse, at first sight. This method they particularly called the *sortes Prænestinae*, and afterwards, according to the poet thus made use of, *sortes Homericae*, *sortes Virgiliana*, &c.

**RHAPSODY**, *ῥαψωδία*, in *Antiquity*, a discourse in verse, sung or rehearsed by a rhapsodist.

Others will have rhapsody properly to signify a collection of verses, especially those of Homer; which, having been a long time dispersed in pieces and fragments, were at length, by Pisistratus's order, digested into books, called rhapsodies; from the Greek *ῥαπίζω*, *scio*, *I scaw*, and *ᾠδή*, *song*.

Hence, among the moderns, rhapsody is also used for an assemblage of passages, thoughts, and authorities, raked together from divers authors, to compose some new piece. Lipsius's Politics make such a rhapsody, in which there is nothing of the author's own but conjunction and particles.

**RHAPTE**, in *Ancient Geography*, the metropolis of the Ethiopians, near the river Raptus. Steph. Byz.

**RHATOSTATHIBIUS**, or, as Baxter thinks it was originally written, *Retostaubius*, a river of the isle of Albion, (England,) on the western side, the mouth of which is placed by Ptolemy between that of the Tobius and the estuary of Sabrina. This is the river Wye, and its ancient name is derived from "Rot in Tat;" the course of a river.

**RHATTA**, a town of Asia, in Babylonia, in the vicinity of Chiriphe. Ptolemy.

**RHAUCUS**, a town of the island of Crete. Steph. Byz.

**RHAVENA**, a prefecture of Asia, along the Euphrates. Ptolemy places in it six towns on the banks of the Euphrates, and four in the interior of the country.

**RHAVIUM**, a river of Hibernia, the mouth of which is placed by Ptolemy between the promontory "Boreum" and the town "Magnata."

**RHAUNEM**, in *Geography*, a town of France, in the department of the Seine, and chief place of a canton, in the district of Birkenfeld. The place contains 547, and the canton 5886 inhabitants, in 35 communes.

**RHAUNETI**, in *Ancient Geography*, a town of Arabia Felix, on the Arabian gulf, between the town "Phœnicum" and the extremity of this Chersonesus. Ptolemy.

**RHAURARIS**, a river of Gallia Narbonensis, according to Strabo. This river is called "Araurius" by Ptolemy, and "Arauraris" by Pomponius Mela.

**RHAUZIUM**, the metropolis of Dalmatia, according to Cedrenus and Curopalata.

**RHAW, GEORGE**, in *Biography*, a learned bookseller and musician of Wittemberg, born in 1494. In 1531 appeared an "Enchiridion utriusque Musicae Practicæ, ex variis Musicorum Libris congestum," in 8vo. And in 1538 he not only published "Select Harmony for four Voices," consisting of two Latin Passiones, the one by John Galliculus, and the other by Jacob Otrecht, with masses, lamentations of Jeremiah, and motets by John Walther, Lewis Senfels, Simon Cellarius, Benedict Dux, Eekel, Lemlin, Stoel, and Henry Isaac, to which Melancthon furnished him with a Latin preface; but in 1544 published, in oblong quarto, 123 German sacred songs, of four and five parts, for the use of schools. Prefixed to the second part of this publication, containing ecclesiastical hymns, set by sixteen different German composers, there is a print of the editor, Geo. Rhaw, Typographus, Wittemb. anno ætatis suæ LIV.

**RHAZES**, one of the oldest and most distinguished of the Arabian physicians, was born at Rei, in the province of Chorasan, about the year 852. There was a school in his native town, at which he received his early education; but he is said not to have commenced the study of medicine till somewhat late in life, having given up his time much to the cultivation of music. After he was thirty years of age, he removed to Bagdad, and then he turned his attention to philosophy, and afterwards to physic. He became, however, indefatigable in his application, and was continually occupied in observing, reading, and writing, until he obtained the highest reputation; and he was selected out of a hundred eminent physicians, who were then resident at Bagdad, to superintend the celebrated hospital of that city. The historians considered him as the Galen of the Arabians; and from his long life and constant practice, during which he paid the most assiduous attention to the varieties of disease, he obtained the appellation of the experimenter, or the experienced. He was said also to be profoundly skilled in all the sciences, especially in philosophy, astronomy, and music. He travelled much in pursuit of knowledge, and made frequent journeys into Persia, his native country, and was much consulted by several princes, particularly by Almanzor, the chief of Chorasan, with whom he frequently corresponded, and to whom he dedicated several of his writings. Abi Osbaia enumerated two hundred and twenty-six treatises composed by Rhazes, among which the *ten* books, addressed to his patron Almanzor, are mentioned, and therefore are doubtless genuine, although Haly Abbas, who has given an account of him and his works, has not noticed them. This work Rhazes designed as a complete body of physic, and it may be deemed the great magazine of all the Arabian medicine; the ninth book, indeed, which treats of the cure of diseases, was in such general estimation for several centuries, that it was the text-book of the public schools, and was commented upon by the most learned professors. Nevertheless, like the rest of the Arabian writings, it contains very little more than the substance of the works of the Greeks, from whom the Arabians borrowed almost all their medical knowledge. They have, indeed, and Rhazes in particular, given the first distinct account of the *small-pox*, a pestilential malady which the Greeks have no where accurately described, and which is, therefore, generally inferred to have been unknown among that people. This is questionable; but, at all events, the first specific account of the small-pox is to be found in the works of Rhazes. He was the author, also, of the first treatise ever composed respecting the diseases of children. His book on the affections of the joints is interesting, and contains an account of some remarkable cures, effected chiefly by copious blood-letting. He describes the symptoms of hydrophobia very well; and also

also some diseases peculiar to eastern countries, as the ignis pernicius, vena medicinis, &c.; and he first noticed the disease called spina ventosa. Rhazes had the reputation of being a skilful alchemist; the art of chemistry, in fact, originated with the Arabians, and Rhazes is the first, as Dr. Freind has shewn, who mentions the use of chemical preparations in medicine. He has a chapter on the qualifications of a physician; and a singular tract on quacks and impostors, in which he has pourtrayed that class of pretenders to the life; and his detail of their pretensions shews that they were at least as numerous, and ingenious in their contrivances of cheater, as in more recent times.

Rhazes lived to the age of eighty, and lost his sight: he died in the year 932. His works that have come down to us, through the medium of translations in Latin, are, 1. A sort of common-place book, entitled "Continens," or "Libri Continentes." 2. A much more perfect work, the "Libri Decem, ad Almanforem," published at Venice, 1510. 3. Six books of aphorisms, published under the title of "Liber de Secretis, qui Aphorismorum appellatur," Bononiæ, 1489. 4. A tract on the small-pox, often translated, and printed with the title of "De Pestilentia;" the best translation is by Channing, London, 1766. Freind's Hist. of Physic. Eloy Dict. Hist. de la Med.

RHAZUNDA, in *Ancient Geography*, a town of Asia, in the interior of Media, between "Sanais" and "Veneca," according to Ptolemy.

RHEA, a town of Asia, in Margiana, according to Ptolemy.

RHEA, in *Mythology*, one of the titles of Cybele, derived from *ρῆω*, *I flow*, on account of that abundance of benefits which she dispenses.

Rhea was, according to Diodorus Siculus, one of the eight great divinities of Egypt; the other seven being the Sun, Saturn or Chronos, Jupiter, Juno, Vulcan, Vesta, and Mercury. Chronos, says this historian, having married Rhea, became, according to some, the father of Osiris and Isis, and, according to others, of Jupiter and Juno. The children of Rhea, by Saturn, were, according to fabulous history, Vesta, Ceres, Juno, Pluto, Neptune, and Jupiter, the father of gods and men; but that god learning from an oracle delivered by Cælus and Terra, that one of his children should dethrone him, devoured them as Rhea brought them forth, which threw her into extreme distress. So that when she was near her time of being delivered of Jupiter, she consulted her parents to know in what manner she might rescue him from the cruelty of his father, and by their advice she secretly withdrew into Crete, where she was delivered, and presented Saturn with a stone wrapped about with swaddling clothes, which he swallowed. Jupiter being grown up, rescued Cælus from the chains with which Saturn had loaded him; and Cælus, in return for his service, gave him thunder, by which he became the sovereign of gods and men. Rhea was one of the names under which the earth was worshipped.

RHEA *Sylvia*, was the mother of Remus and Romulus; and in order to give dignity to their origin, the fable reports that her uncle Amulius got into her cell, and her father Numitor propagated the story that the twins she brought forth had been begotten by the god of war.

RHEA, in *Ornithology*, a species of the struthio or ostrich, the same bird with the *nhan-duguacu* of the Brasils. See STRUTHIO.

RHEBAN, in *Ancient Geography*, a river of Asia, in Bithynia. According to Arrian, the source of this river was on mount Olympus, and its mouth in the Euxine sea, near that of Phillis.

RHECHIUS, a river of Greece, which discharged itself into the sea near Thessalonica. At the mouth of this river Justinian erected a fort called "Artemisa."

RHEDA, in *Geography*, a town of Germany, the capital of a lordship, in the county of Linggen; 10 miles N. of Lippertadt. N. lat. 51° 47'. E. long. 7° 50'.

RHEDA, a town of Holland, in Guelderland, on the Issel; seven miles N. of Arnheim.

RHEDONES, in *Ancient Geography*, a people of Gaul, in Armorica, according to Cæsar and Ptolemy.

RHEEDIA, in *Botany*, called Vanrheedia by Plumier, in honour of a most illustrious promoter of the study of East Indian plants, Henry Van-Rheede Van-Draakenstein, to whose judgment and munificence, while governor of Malabar towards the latter part of the 17th century, the publication of that splendid work the *Hortus Malabaricus*, in 12 folio volumes, is owing.—Linn. Gen. 260. Schreb. 348. Mart. Mill. Dict. v. 4. Juss. 258. Lamarck Illustr. t. 457. (Vanrheedia; Plum. Gen. 45. t. 18.) Class and order, *Polyandria Monogynia*. Nat. Ord. *Guttifera*, Juss.

Gen. Ch. Cal. none. Cor. Petals four, sessile, obovate, concave, spreading. Stam. Filaments numerous, thread-shaped, longer than the corolla; anthers oblong. Pist. Germen superior, ovate; style cylindrical, the length of the stamens; stigma funnel-shaped. Peric. Berry ovate, thin, of one cell. Seeds three, very large, ovate-oblong, marked with simple or branched lines.

Ess. Ch. Petals four. Calyx none. Berry superior, with three feeds.

1. *R. lateriflora*. Linn. Sp. Pl. 719. (Vanrheedia folio subrotundo, fructu luteo; Plum. Ic. 255. t. 257.)—Native of South America. A tree known only to Plumier, whose figure represents it with large, opposite, stalked, ovate, entire leaves; axillary tufts of numerous, rather small, flowers; and ovate pendulous fruit, about two inches long. Jussieu doubts whether the calyx be really wanting.

Linnæus does not appear to have ever had a specimen of this plant; nor can we account for his striking out (in Mant. 401.) the observation in his Sp. Pl. for which he has substituted, in Syst. Veg., the following description, taken from some East Indian specimen, as his original manuscript shews, and certainly foreign to the true *Rheedia*. "A tree, with jointed, compressed, even, downy branches. Leaves opposite, stalked, lanceolate, entire, smooth. Footstalks short, downy. Flower-stalks axillary, about three together, three cleft, three-flowered."

Willdenow has omitted this genus, in its proper place, nor have we discovered what he has done with it.

RHEGADORA, in *Ancient Geography*, a town of Asia, in Cappadocia.

RHEGIANUM, a town of Lower Mæsia, on the bank of the Danube. Ptolemy.

RHEGIAS, a town of Asia, in Syria: according to Ptolemy it was in Cyrrhælica, between Ariferia and Ruba.

RHEGIUM, or REGIUM, (*Reggio*), a town of Italy, at the extremity of Brutium, in the Strait of Sicily. In the time of Dionysius the tyrant, the inhabitants of Rhegium formed a league against him, which terminated in a treaty in the year 354. A difference afterwards occurring between them, he besieged the town and took it, after about eleven months, in 365. The conduct of Dionysius during this siege was in the highest degree savage and brutal. Rhegium afterwards became subject to the Romans; but a legion, encouraged by the example of the Mamertins of Messina, revolted in 472, and took possession of the city. After ten years' possession, it was besieged by the Romans, and those who escaped the destruction of the siege, to the amount

amount of about 300, were carried to Rome, where they were scourged and beheaded. This city suffered much from the earthquake that ravaged Calabria; and even in the time of the Romans it was abandoned by its inhabitants, on account of the calamities which it had suffered; but Cæsar rebuilt it, after having driven Pompey from Sicily. Virgil (l. iii. v. 414, &c.) thus describes it:

“Hæc loca vi quondam, et vastâ convulsa ruina  
(Tantum Ævi longinqua valet mutare vetustas)  
Dissiluisse ferant, quam protenus utraque tellus  
Una foret; venit medio vi pontus, et undis  
Hesperium Siculo latus abscidit arvaque et urbes  
Littore diductas angusto interluit æstu.”

**RHEGMA**, a place of Asia, in Cilicia, at the mouth of the river Cydnus. Strabo.—Also, a town of Arabia Felix, on the coast of the Persian gulf, in the country of the Anarites. Ptolemy.

**RHEGMA**, formed of *ῥήγνυμι*, *I break*, a word used by the ancients to express any breaking or bursting of a soft part without a wound, but most frequently for abscesses breaking inwardly.

**RHEID**, in *Geography*, a town of France, in the department of the Roer; 2 miles E. of Gladbeck.

**RHEIMS**. See **REIMS**.

**RHEIN**, a town of Prussia, in the province of Natangen, on a lake which communicates with Spirding lake. It has a large fortified castle, and an inferior court of justice; 68 miles S.E. of Königsberg. N. lat. 53° 48'. E. long. 21° 42'.

**RHEINAU**, a town of France, in the department of the Lower Rhine, situated on the Rhine, and very much reduced by the inundations of the river; 5 miles S. of Straßburg.—Also, a town of Switzerland, in the Thurgau, situated on an island formed by the Rhine, with a convent; 5 miles S.S.W. of Schaffhausen.

**RHEINBACH**, a river of Saxony, which joins the Loderbach, near Bitterfeld.

**RHEINBACH**, a town of France, in the department of the Rhine and Moselle, and chief place of a canton, in the district of Bonn. The place contains 1119, and the canton 16,478 inhabitants, in 37 communes.

**RHEINBECK**, a town of the duchy of Holstein; 10 miles E. of Hamburg.

**RHEINBERG**, a town of France, in the department of the Roer, and chief place of a canton, in the district of Creveldt; 44 miles N.W. of Cologne. The place contains 1705, and the canton 7166 inhabitants, in 17 communes.

**RHEINE**, or **REINEN**, a town of Germany, in the bishopric of Münster, on the Embs, near which are some salt springs; 22 miles N. of Münster. N. lat. 52° 21'. E. long. 7° 25'.

**RHEINECK**, or **RHEINEGG**, a town of Switzerland, and capital of the Rheintal, situated on the Rhine, near its confluence with the lake of Constance, inhabited chiefly by Protestants; 26 miles S.E. of Constance.

**RHEINFELDEN**, a town of Germany, and lately one of the four forest towns of Austrian Swabia, on the S. side of the Rhine, on the opposite bank of which is a covered way, built like a horn-work, and communicating with the town by means of a bridge; 9 miles E. of Bâle. N. lat. 47° 35'. E. long. 7° 50'.

**RHEINFELS**. See **RHEINFELS**.

**RHEINHAUSEN**, a town of Baden, in the circle of the Upper Rhine, on the E. side of the Rhine; 3 miles S.E. of Spire.

**RHEINMAGEN**. See **REMAGEN**.

VOL. XXX.

**RHEINSDORF**. See **RONSDORF**.

**RHEINTHAL**, a bailiwick of Switzerland, between the canton of Appenzel and the Rhine, belonging to the nine cantons, about 30 miles long, and from three to eight broad. The country is fertile, and produces excellent wine. The number of inhabitants is about 13,000, who are partly Protestants and partly Roman Catholics.

**RHEINWALD**, a valley in the country of the Grisons, about 20 miles long, which takes its name from a branch of the Rhine that passes through it.

**RHEMAN**, or **REMAN**, in *Ancient Geography*, a fortified place of Asia, in Mesopotamia, which belonged to the Romans, according to Ammianus Marcellinus.

**RHEMBA**, in *Hindoo Mythology*, is a character corresponding in many parts to the popular Venus of the Greeks. Like her she sprang from the foam of the ocean, when churned by the gods and demons for the purpose of obtaining the amrita, or beverage of immortality, as noticed under the articles **KURMAVATARA** and **LAKSHMI**. She is sometimes said to be an incarnation of Lakshmi, consort of Vishnu. More correctly, however, she is stationed in the court of Indra, as the chief of his bands of celestial choristers, named Apsaras, Devangana, Gandharva, &c. The Apsaras, or Upfaras, are the Nereids of the Hindoo Pantheon: having sprung from water, they are called water nymphs, and assist Indra, the Jupiter Pluvius of India, in his regency over aqueous phenomena. (See **UPSARA**.) In the churning process above adverted to, these fair damsels were produced in extravagant numbers, according to the Ramayana, viz. 600 millions! “of resplendent and celestial form; adorned with glorious ornaments, and endowed with beauty, youth, sweetness, and every grace.” These interesting offspring of poetical imagination are proverbially elegant and graceful. The three wives of the mortal father of Ramachandra are said, in the work just quoted, to be queens, who, “in elegance of form, rivalled the Apsaras.” As the chief of these damsels of Paradise, the subject of this article is sometimes titled Rhemba-devi, or the goddess Rhemba.

In Hindoo writings, especially in amatory poetics, allusions frequently occur to the Upfaras, who correspond also with the fairies of the Persians. Many are mentioned by name, Rhemba the oftenest, Urvashi, Tilotamma, Menaka, &c. (See those articles.) Under the name of the last we have given an instance of the use made by Indra of these obsequious fulfillers of his will; for, as well as in the line of singing, dancing, &c. condescensions to the Indra-dikas, or the demi-gods, the Apsaras are the fascinating disturbers of holy men, when engaged in such fervent austerities as threaten the safety of Indra in his firmamental throne. In explanation of which, it requires to be noticed that Indra was originally a mere mortal; but learning that the throne of heaven was the reward of the man who should, with the prescribed ceremonies, perform one hundred atwamedhas, or sacrifices of a horse, he did so, and obtained his dominion, and the name of Slatkratu, or he who performs a hundred sacrifices. (See **INDRA**.) His throne he retains until another mortal shall equal or exceed him in this potent title of propitiation. He is, therefore, always on the watch; and being all eyes, never fails to discover austere saints while performing their rigid duties; when he either steals or desiles the horse intended and sanctified for the next sacrifice, or detaches Rhemba or Menaka, or some other of his damsels of “fascinating symmetry of form,” who always succeed in exciting emotions incompatible with the required purity of such as aspire to oust Indra from his ethereal throne. See **MENAKA**.

The name Apfara is sometimes written *Upfara*, under which latter word something farther concerning these damfels will be found.

RHENA, in *Geography*, a town of Germany, in the duchy of Mecklenburg; 22 miles W.S.W. of Wismar. N. lat.  $53^{\circ} 50'$ . E. long.  $11^{\circ} 10'$ .

RHENANUS, BEATUS, in *Biography*, a learned German, was born at Rheinau in 1485, and died at Strasburgh in 1547. He was corrector of the prefs for Frobenius, and by that means formed an intimacy with Erasmus. He wrote "A History of Germany," 4to.; "Illyrici Provinciarum utriusque Imperiorum Romano, tam Constantinopolitano Servientis, Descriptio," 8vo. He was also the editor of Velleius Paterculus, and other works.

RHENA, in *Ancient Geography*, an island of the Ægean sea, in the neighbourhood of that of Delos. Strabo says that it was deserted, but that it was the place of burial for the inhabitants of Delos; which being deemed sacred, it was forbidden to bury the dead in it. The two isles of Delos and Rhenea are called "Dili or Isdiles."

Rhenea retains its name, and is denominated also Great Delos; it is separated from the famous island of Delos by a strait of about 500 toises. In the middle of this narrow channel are two shoals, called the Great and the Little Ramateari: the ancient Greeks had consecrated the larger to Hecate or Diana, and called it the island of Hecate, or Pfanmite. Ships, even men of war, find good anchorage near this island. N. lat.  $37^{\circ} 10'$ . E. long.  $25^{\circ} 15'$ . See DELOS.

RHENEN, in *Geography*, a town of Holland, in the department of Utrecht, seated on the river Leck; 20 miles N.N.E. of Bois-le-Duc. N. lat.  $51^{\circ} 59'$ . E. long.  $5^{\circ} 30'$ .

RHENFERD, JAMES, in *Biography*, a celebrated oriental scholar, was born at Mulheim, in Westphalia, in the year 1654. He went through a course of academical studies at the college of Meurs, a city in the duchy of Cleves, and afterwards travelled for improvement into foreign countries. In 1678, when he was 24 years of age, he accepted an invitation to become rector of the Latin college in the city of Franeker; but upon the condition that, while he held that post, he should be at liberty to deliver lectures on the Oriental languages. He resigned his rectorship and removed to Amsterdam, where some of the most wealthy families in that city employed him in the capacity of tutor, and he enjoyed, at the same time, a favourable opportunity for conversing with learned Jews, and improving his knowledge of rabbinical learning. In the year 1683, a vacancy having taken place in the professorship of the Oriental languages and sacred philosophy at the university of Franeker, by the removal of the famous Vitringa to the theological chair, M. Rhenferd received an invitation to fill it; which he accepted. M. Rhenferd held this post nearly thirty years, during which he had the honour of being thrice chosen rector of the university. He died in 1712, when he was in the 59th year of his age. His learning was general and extensive; but he chiefly excelled in an acquaintance with the Hebrew, including the Rabbinical, the Chaldee, and Syriac. He was author of several learned works, among which the following may be mentioned; "De Antiquitate Characteris hodierni Judaici," 1696, 4to.; in which he endeavoured to establish the claim of the present Hebrew characters to the highest antiquity, and to prove that the Samaritan characters were borrowed from the Hebrews; "Comparatio Expiationis anniversariæ Pontificis maximi in Vet. Test. cum unica atque æterna Expiationis Christi Domini;" "Investigatio Practicorum et Ministrorum Synagogæ," 1700, 4to.; "Dissertationum

Theologico-philologicarum de Stylo Novi Testamenti Syn-tagma, quo continentur Olearii, Cocceii, &c. de hoc genere Libelli," &c. 1701, 4to.; "Arabarcha, feu, Ethnarcha Judæorum," 1702, 4to.; "De Statuis et Aris, falsis verisque Dei et Hominum Internunciis," in illustration of Exod. xx. 23, 24, 1705, 4to.; "Observationum selectarum ad Loca Hebræa Nov. Test. partes five Disput. Tres," 1705, 4to. &c. In 1706 he commenced the publication of a work, entitled "Rudimenta Grammaticæ Harmonicæ Linguarum Orientalium, Hebrææ, Chaldaicæ, Syriacæ, et Arabicæ," which he did not live to finish.

RHENONES, among the ancient Germans, a kind of garment covering the shoulders and breast down to the middle. It was either entirely made of skins, or covered over with them; the long hair of which being outward, proved a good defence against rain.

RHENUS, in *Geography*. See RHINE.

RHEO-STATICS, is used by some for the statics, or the science of the equilibrium of fluids.

RHERIGONEUS SIXUS, in *Ancient Geography*. See RERIGONIAN Bay.

RHESAPHĀ, a town of Syria, in the Palmyrene, near Cholle. Ptol.

RHESCIPIA, or RESCHIPHIA, a town of Asia, in Mesopotamia, upon the banks of the Euphrates, between Bithauna and Agamana. Ptol.

RHESINA, a town of Asia, partes Mesopotamia, on the river Aboras. Steph. Byz.

RHETICUS, GEORGE JOACHIM, in *Biography*, an excellent German astronomer and mathematician in the 16th century, and a native of Feldkirk, the chief town of one of the western counties of the Tyrolse, was born in the year 1514. Discovering early an inclination towards the study of the mathematics, he was initiated in the elements of that science at Zurich; whence he removed to the university of Wittenberg: here he took the degree of master of philosophy in 1535, and two years afterwards he was made joint professor of the mathematics and astronomy with the famous REINHOLD. (See his article.) While he was daily rising into reputation by his lectures, he was informed of the hypothesis of Copernicus concerning the revolution of the heavenly bodies; which appeared to him to be so reasonable, that he determined to resign his professorship, and study the doctrine under the instructions of its author. Accordingly, in 1539, he left Wittenberg, and went into Prussia, where he became a disciple of that great man. To the system of Copernicus he soon became an entire convert; and he afterwards assisted his master for some years in his astronomical labours. In vain did he for a long time urge Copernicus, in common with the other friends of that astronomer, to favour the world with his grand work, "De Revolutionibus Orbium Cœlestium." At length, the persuasions of his friends having prevailed upon Copernicus to permit the appearance of his work, the care of editing it was confided to Rheticus, who caused it to be printed at Nuremberg in 1543, in folio. He now began his very elaborate "Canon Doctrinæ Triangulorum," or canon of sines, tangents, and secants, to fifteen places of figures, and to every ten seconds of the quadrant: a design which he did not live to complete. The canon of sines, however, to the same radius, for every ten seconds, and for every single second in the first and last degree of the quadrant computed by him, was published at Francfort in 1613, folio. Upon the death of Copernicus, who lived only a few hours after he received a copy of his printed work, Rheticus returned to Wittenberg, and was again admitted to his post of mathematical and astronomical professor. For some time after

after this he taught the mathematics at Leipzig; and he afterwards left Saxony a second time, and went into Poland. In the year 1576, upon the invitation of a Hungarian nobleman, he went to Caffavia in Hungary, where, in consequence of sleeping in a room recently plaitered, he caught a disorder on his lungs, which proved fatal to him in the 63d year of his age. He composed and published "Ephemerides," according to the doctrine of Copernicus, till the year 1551; "Orationes de Astronomia, Geometria, et Physica," &c.

**RHETORIANS, RHETORII**, a sect, in the fourth century, in Egypt, so nominated from their leader Rhetorius.

His distinguishing doctrine, as represented by Philastrius, was, that he approved of all the heresies before him, and taught that they were all in the right. But what Philastrius mentions of him appears so absurd and ridiculous, that St. Augustine, Hæres. 7, could not persuade himself it was true.

**RHETORIC, RHETORICA**, formed from ῥητορικῆς, of ῥηω, I speak, whence ῥητωρ, speaker, orator, &c. the art of speaking copiously on any subject, with all the advantages of beauty and force.

Rhetoric is generally considered as the art of persuasion. It attempts to produce conviction concerning some particular object, that it may influence the will to a corresponding determination. It seeks either to arouse the mind to action, or to dissuade it from acting upon the resolutions already taken, or such as are in contemplation. Its immediate employment is not to search after truth, but to render acknowledged or supposed truths influential. It leaves to logic the province of cool investigation, and of drawing legitimate conclusions from admitted premises, without any regard to motives. The rhetorician is solicitous to effect some particular purpose, and calls in the art of reason merely as an auxiliary. He attempts to influence the will by reasoning with the affections; knowing that if they be gained over to the party espoused, the will is ready to follow. He, therefore, artfully conceals, or slightly passes over, every circumstance which is not favourable to his views, and brings forwards and largely expatiates upon those which are. He suggests motives of pleasure, utility, safety, honour, pity, &c. as the subject admits. He not only pre-supposes the object in view of the first importance, but he employs every method to implant this conviction in the minds of those whom he endeavours to persuade. These attempts become most successful by a close imitation of that train of ideas, and those modes of expression, which any particular passion or affection is prone to suggest. If the design be to excite *anger* and *resentment*, rhetoric imitates the language of anger. It places the supposed offence in the strongest point of view, and describes it in the most vivid colours. It assiduously collects and expatiates upon every circumstance which contributes to the aggravation of the crime. It is indignant against that spiritless tranquillity which can patiently endure such insults, and attributes reluctance to revenge to mean and cowardly motives. If its object be to excite *horror*, it assembles together every circumstance which has a tendency to alarm with a sense of danger. It stigmatizes courage with the epithet of rashness, and slight is dignified with the title of prudence, &c. If *compassion* be the object, it expatiates upon the wretched state of the sufferer; his fears, his apprehensions, his penitence. It palliates his faults, extols his good qualities, and thus collects, in one point of view, all his claims on commiseration. The species of argument, which persons under the influence of passions and strong affections perpetually adopt, is rendered more efficacious by appropriate language.

The rhetorician, therefore, studies and imitates the particular language of each passion, either in its energy, vivacity, or diffuseness. Hence he liberally employs all those tropes and figures of speech which nature suggests, and art has classified.

*Oratory* adds to rhetorical composition the advantages of *elocution*. It adapts the manner of delivery to the nature of the subject and the appropriate language. It takes the characteristic signs of each emotion for its model, as far as it dares to imitate, without the imputation of mimicry; it enters into the attitudes, gestures, tones of voice, accents, emphasis, expressions of countenance, inspired by the particular emotion, in such a manner, that not an idea is suffered to lose its proper effect, by any deficiency in kind or degree of energy communicated to it; and thus it enjoys every advantage to be derived from the power of sympathy.

*Eloquence*, according to the modern ideas of it, appears to be the medium between the impetuosity which oratory admits, and which was highly characteristic of ancient oratory, and the studied artifice of the professed rhetorician. The term is sometimes applied to *composition*, and sometimes to *delivery*. When applied to both, it comprehends a certain degree of elegance, both of diction and of manner. The want of that energy which approaches to violence, is compensated by pertinency of language, fluency of utterance, and guarded chastity of address. In a word, its excellency consists in a pleasing adaptation of language to the subject, and of manner to both. It refuses too close an imitation of the turbid emotions, but it delights in animated description. It seems rather partial to the pathetic; the elegance and graces which it loves, harmonize most easily and successfully with the softest and finest feelings of our nature. (Cogan on the Passions.) **RHEU, LA**, in *Geography*, a town of France, in the department of the Ille and Vilaine; five miles W.S.W. of Rennes.

**RHEUM**, in *Botany*, a name derived, as Linnaeus supposes, from ῥηω, to flow, on account of its active medicinal properties. The Ρῥῆζ, or Ρῥ, of Dioscorides is probably of this genus, and the origin of the name.—Linn. Gen. 201. Schreb. 271. Willd. Sp. Pl. v. 2. 488. Mart. Mill. Dict. v. 4. Ait. Hort. Kew. v. 2. 430. Juss. 82. Gærtn. t. 119. Lamarek Dict. v. 6. 192. Illustr. t. 324. (Rhubarbarum; Tournef. t. 18.) Rhubarb.—Class and order, *Euneandria Monogynia*. Nat. Ord. *Holeraceæ*, Linn. *Polygonææ*, Juss.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, narrowed at the base, withering, but permanent, cloven into six obtuse segments, alternately smaller. *Cor.* none, except the three inner segments of the calyx be considered such, as in *Rumex*. *Stam.* Filaments nine, capillary, equal in length with the calyx, and inserted into it; anthers twin, oblong, obtuse. *Pist.* Germen superior, short, triangular; styles scarcely any; stigmas three, reflexed, feathery. *Peric.* none. *Seed* solitary, large, triangular, acute, with membranaceous margins.

Ess. Ch. Calyx six-cleft, permanent. Seed one, triangular.

1. *R. Rhaponticum*. Rhapontic Rhubarb. Linn. Sp. Pl. 531. Alpin. Rhapont. 1. t. 1. — "Leaves obtuse,

U 2 smooth;

smooth; veins somewhat hairy beneath; the sinus dilated at the base: stalks furrowed on the upper side, rounded at the edge."—Native of Asia, and cultivated, like all the other species (except *Leucorrhizum*), at Kew, where they mostly flower in May and June.—*Root* large and thick, much divided, reddish-brown on the outside, yellow within. *Stems* from two to three feet high, jointed, purple. *Leaves* not expanded at first, but folded, smooth, roundish heart-shaped, on thick, reddish, channelled stalks, which have an acid flavour, and are used for making tarts. *Flowers* white, forming a thick, obtuse, dense tuft, which becomes a panicle of large, triangular, brown seeds.

2. *R. undulatum*. Waved-leaved or Chinese Rhubarb. Linn. Sp. Pl. 531. Amœn. Acad. v. 3. 230. t. 4.—“Leaves rather hairy, undulated; the sinus dilated at the base: stalks flat above, sharp at the edges.”—Native of China and Siberia.—*Root* composed of numerous thick fibres, running further into the ground, and of a deeper yellow than the foregoing. *Stem* upright, three or four feet in height, of a pale brownish colour. *Leaves* somewhat tapering, much waved at their edges, strongly veined beneath. *Flowers* white, in loose panicles or bunches. *Seeds* of a rusty brown.

3. *R. palmatum*. Official or Turkey Rhubarb. Linn. Sp. Pl. 531. Mill. Illustr. t. 30. Woodv. Med. Bot. 127. t. 46.—“Leaves palmate, pointed, roughish; the sinus dilated at the base: stalks obsolete furrowed above, rounded at the edge.”—Native of China and Tartary.—*Root* perennial, thick, oval, sending forth numerous tapering branches, externally brown, internally yellow. *Stem* erect, six or eight feet high, round, hollow, jointed, sheathed, slightly furrowed, branched towards the top. *Radical-leaves* numerous, large, rough, roundish, deeply lobed; *stem-leaves* one at each joint, from a membranous sheath, smaller upwards. *Flowers* of a greenish-white colour, surrounding the branches in numerous clusters, forming a kind of spike.

The roots of this and the last species constitute the drugs which in our shops are known by the names of Chinese and Turkey Rhubarb, although other species of *Rheum*, especially *compactum*, possess like medicinal properties, and their roots are of course sometimes substituted for the true ones. Professor Martyn and Dr. Woodville have taken great pains to illustrate this genus, so justly celebrated for its purgative qualities. Dr. Pulteney remarks, that if *R. undulatum* and *R. palmatum* are planted near each other, they produce a hybrid variety, more excellent in kind than the parent plants.

4. *R. compactum*. Thick-leaved Rhubarb. Linn. Sp. Pl. 531. Mill. Ic. v. 2. 145. t. 218.—Leaves somewhat lobed, very obtuse, lucid, sharply toothed, quite smooth.—Native of Tartary.—*Roots* large, much divided, yellow within. *Stems* five or six feet high, green, branched at the upper part. *Leaves* long, broad at the base, coriaceous and compact, rather waved, and having a sharp acid flavour. *Flowers* white, forming an erect panicle or spike. This is frequently substituted for the real rhubarb.

5. *R. tartaricum*. Tartarian Rhubarb. Linn. Suppl. 229. Willd. n. 5.—Leaves ovate, heart-shaped, undivided, flat, smooth, on roundish, angulated stalks. Panicle furrowed.—Native of Lesser Tartary. We know of neither specimen nor figure of this species. Linnæus described it from the Upsal garden as having large leaves, the radical ones procumbent, with dilated veins, on red stalks, which are convex beneath. *Inflorescence* scarcely higher than the leaves.

6. *R. Ribes*. Warty-leaved Rhubarb. Linn. Sp. Pl. 532. Desfont. in Ann. du Mus. v. 2. 261. t. 49. (La-

pathum orientale, aspero et verrucoso folio, Ribes Arabibus dictum; Dill. Elth. v. 1. 191. t. 158. f. 192.)—Leaves very obtuse, verrucose, with spinous veins beneath; stalks flat above, rounded at the margin.—Native of the Levant; on mount Libanus, and other mountainous parts of Syria.—*Root* thick and fleshy. *Stems* two feet high, hairy, green, tinged with purple towards the bottom. *Leaves* large, curled at the edges, veined, of a purplish-green colour, paler beneath, studded with warts. Linnæus, who had never seen the flower, referred this plant to *Rheum* from its habit.

7. *R. hybridum*. Bastard Rhubarb. Willd. n. 7. Murray in Comment. Gott. 1779, 7. t. 1. Leaves smooth above, rather hairy beneath, slightly lobed, acute; the sinus narrowed at the base; stalks obscurely furrowed above, rounded at the margin.—Native of the north of Asia.—Very similar in habit and appearance to *R. palmatum*, and we are much disposed to consider it, with professor Murray, as a hybrid plant produced between that and some other species. The leaves of this are not so much nor so deeply cut as those of *palmatum*.

8. *R. leucorrhizum*. White-rooted Rhubarb. Willd. n. 8. Pallas Nov. Act. Petrop. 1792, 381.—Leaves transversely oval, depressed. Panicle divaricated when in seed. Two segments of the calyx many times larger than the rest.—Native of desert places, on the mountains of Siberia.—Adopted by Willdenow, on the authority of Pallas, who describes it thus. “*Radical-leaves* usually three, procumbent, four or five inches wide, three-nerved, much veined, smooth, coriaceous, lengthened out at the base; rough at the edges, with very minute, cartilaginous, acute crowded teeth. *Stalks* compressed, smooth, solid, succulent. *Flowering-stem* a span high, furrowed, paniced.”

RHEUM, in Gardening, contains plants of the herbaceous, perennial, luxuriant kind, of which the species chiefly cultivated are; the rhapontic or common rhubarb (*R. rhaponticum*); the palmated-leaved (*R. palmatum*); the compact thick-leaved rhubarb (*R. compactum*); the waved-leaved Chinese rhubarb (*R. undulatum*); the warted-leaved Persian rhubarb (*R. Ribes*); and the Tartarian or heart-leaved rhubarb (*R. tartaricum*.)

It is stated, on the authority of several cultivators of the first species of this plant, by the editor of Miller's Dictionary, that by proper attention in the growth and preparation of the root, it may be obtained here nearly in equal goodness to the foreign.

*Method of Culture*.—These plants are all increased by seeds, which should be sown in autumn soon after they are ripe, where the plants are designed to remain, as their roots being large and fleshy when they are removed, they do not recover it soon; nor do the roots of such removed plants ever grow so large and fair as those which remain where they were sown. When the plants appear in the spring the ground should be well hoed over, to cut up the weeds; and where they are too close, some should be cut up, leaving them at the first hoeing six or eight inches asunder; but at the second, they may be separated to a foot and a half distance, and more. When any weeds appear, the ground should be scuffled over with a Dutch hoe in dry weather; but after the plants cover the ground with their broad leaves, they keep down the weeds without any further trouble. The ground should be cleaned in autumn when the leaves decay, and in the spring, before the plants begin to put up their new leaves, be dug well between them. In the second year, many of the strongest plants will produce flowers and seeds, and in the third year most of them. It is advised, that the seeds be carefully gathered when ripe, and

not permitted to scatter, lest they grow and injure the old plants.

The roots continue many years without decaying, and it is said that the old roots of the true rhubarb are much preferable to the young ones. The roots may be generally taken up after four years, but if they remain longer, it is so much the better.

These plants delight in a rich soil, which is not too dry nor over moist: and where there is a depth in such land for their roots to run down, they attain a great size, both in the leaves and roots.

Some cultivators think that the sowing is best performed in the later spring months; but in this way, as the seeds are slow in vegetating, there is much time lost. And a hot-bed has been sometimes employed, though it is not much advised.

The rhubarb plants may be also increased from offsets, separating some of the eyes or buds which shoot out on the upper parts of the root, together with a small part of the root itself, having some of the fibres to it. These offsets may be taken from roots of three or four years old, without any injury to the plant. By this method a year is saved, and the plants are not in such danger of being devoured by vermin as those from seed, nor so uncertain in growing; they are not so tender, and only require keeping clear of weeds. There is no difference in the size of the roots thus raised, from those which grow from seeds. This method was practised by Mr. Hays, and in Mr. Hayward's practice several offsets were slipped from the heads of large plants in the spring, and set with a dibble about a foot apart. Four years after, he took up the roots, and found them very large, and of excellent quality. On further experience, when he took up his roots, either in spring or autumn, he divided the head into many parts; these he planted directly, at two feet distance, if intended for future removal; but if to remain for a crop, at four feet and a half.

And in the culture of this root for medicinal uses, the nature of the aspect is said not to be very material, provided it be not shaded too much on the south or west. The indispensable points are the depth and good quality of the soil, which should be light, loamy, and rich, but not too much so, lest the roots be too fibrous: it can scarcely be too dry, for more evil is to be expected from a superabundance of moisture than from any actual want of it. If, with these advantages, the plantation can be placed on a gentle declivity, such a situation may be said to be the most desirable. Where a plantation does not possess the natural advantage of being on a declivity, narrower beds and deepened trenches are among the artificial means that should be adopted; but most situations will require some care to prevent the ill effects of water remaining on the crowns of the plants: therefore, when the seed-stalks are cut off, which ought always to be done immediately upon the withering of the radical leaves, they should be covered with mould, in form of a hillock. This process will answer two good purposes; that of throwing off the rain, and keeping open the trenches by taking the earth from them. And it is observed, that the injuries to which the young plants are most liable, are from slugs and other vermin, from inattention to the season and manner of planting, and from too great an exposure to frost. Little damage is to be feared from heat; and, in general, they are hardy and easy of cultivation when arrived beyond a certain term. It is advised to take great care of the nursery bed, as the pains bestowed by constant waterings, and protecting the young plants from the ravages of insects, will amply repay the planter. Roots that thrive well here, will in three years arrive at an equal size with

others, that have not succeeded so well at the end of five. When a plantation is to be formed, or a vacancy filled up, select the finest and most thrifty plants. No plant will come to any thing when it has lost its principal bud.

It is also observed, that there is a difference of opinion in respect to the age at which the roots ought to be taken up for use; but it is probably best done from four to eight years. They are the best when taken up in autumn, in a dry time, and should be immediately dried and prepared by cutting into pieces and cleaning, hanging them on proper strings in a dry airy place.

And some plants of each of the sorts may also be introduced in the dry borders and clumps, for the ornamental effect of the leaves and flowers.

**RHEUM**, in *Medicine*, *ῥευμα*, *defluſion*, a term which was in common use in the vocabulary of the humoral pathologists, to denote the fluid discharged from a part, as of mucus in coryza and catarrh, and also a supposed accumulation or congestion of fluid in a part. In their doctrine every inflammation and tumour was ascribed to a defluſion of some humour in the part affected; but modern observation has taught us, that the accumulation of fluid, in these cases, is generally the effect, and not the cause, of the disease; being the consequence of inflammatory action of the vessels, which produces an increased discharge and an altered condition of their secreted fluids. Although the term and the doctrine are both exploded, they have left a popular appellation attached to a disease, which is universally called *rheumatism*.

**RHEUMATISM**, from the preceding word, a painful disease usually affecting the joints, and sometimes the muscles. The appellation seems to have been first limited to this disorder by a celebrated French writer, Baillou, or, as he calls himself in Latin, Ballonius; and has since been adopted both by the erudite and the vulgar.

Rheumatism assumes two or three forms, remarkably different from each other, independently of the varieties which difference of seat occasions; a difference, indeed, which is rather nominal than real. Of the latter distinctions, we have *lumbago*, when the disease is seated in the loins (*lumbi*); *ischiatic*, or *sciatica*, when it occurs in the hip; and *pleurodyne*, when it attacks the sides, which are lined with the membrane called *pleura*, &c. The more remarkable species of the disease, however, to which we have alluded, are the *acute* and *chronic* forms which it exhibits. There is also a third form, partaking more of the acute than of the chronic species, which has been called, with some impropriety, *rheumatic gout*, or *arthritis rheumatica*. It will be necessary to speak of the acute and chronic rheumatism, as well as of the rheumatic gout, separately; since the treatment, which they respectively require, is considerably different.

**RHEUMATISM**, *Acute*, otherwise called *rheumatic fever*, begins, like most other febrile diseases, with fits of chilliness, which are succeeded by increased heat, frequent pulse, thirst, loss of appetite, and prostration of strength. Not unfrequently, however, the peculiar symptoms appear before any febrile symptom is observed; namely, pain and inflammation in the joints. The pain sometimes affects the joints alone, but often it affects also the muscular parts, shooting along the course of the muscles from one joint to another; and it is always increased by the action of the muscles, that is, by any attempt to move the joints that are diseased. Its usual seat is in the larger joints, such as the hips, knees, shoulders, and elbows: the ankles and wrists are also frequently attacked; but the smaller joints, such as those of the toes and fingers, suffer considerably less. Two, three, or more of these joints are commonly affected at the same time;

time; but the pain is constantly shifting its place, leaving some joint and going to another, and frequently returning again to each of them several times during the course of the disease; and in this manner the disease is often protracted for a considerable length of time. Soon after, and sometimes at the same moment with the commencement of the pain, the joint seized becomes swelled and somewhat red; and this swelling is extremely painful to the touch. The pain is sometimes relieved by the occurrence of swelling, but not always; neither is the joint thus rendered more secure from a return of the attack. The patient, thus unable to move the joints affected, which are irritated and acutely pained by external contact, sometimes even by the weight of the bed-clothes, and in a state of severe internal pain, unable to find any position of ease, lies sleepless and restless for several days and nights together. The fever accompanying the disease is most considerable during the night, at which time the pains also are most violent. The pulse is commonly from ninety to a hundred in a minute, and occasionally more frequent; often full, and sometimes hard and sharp, but most frequently soft. The heat of the skin is considerable, and the disease is commonly attended with sweating, even from an early period, which is often profuse and constant, but never either relieves the pains permanently, or proves a crisis to the fever. The urine, in acute rheumatism, is remarkably high-coloured from the beginning, and afterwards deposits most copiously a brownish-red sediment, like brick-dust. This sediment, however, is probably the result rather of the profuse sweating, than of any peculiarity belonging to the disease; since it is commonly seen after a dose of sudorific medicine, or any other variety of perspiration. Like the sweating, it does not occasion or betoken any favourable change in the fever. When blood is drawn in this disease, it always exhibits, and generally in a high degree, the buffy coat, as it is called, or a coriaceous covering of coagulable lymph, on its surface.

With the symptoms above detailed, the rheumatic fever often continues for several weeks: it seldom, however, proves fatal, and perhaps never, while the joints alone are the seat of the disease; the fever, indeed, usually becomes less violent after two or three weeks, and the pains less severe, and less disposed to change their place. But occasionally the inflammation of the joints has disappeared, and some vital organ, as the brain, lungs, or stomach, has been seized with inflammation, by which the patient has been carried off; or these organs have become simultaneously affected, and the same fatal event has ensued. We have had occasion to witness two instances of this kind, out of several hundreds of cases, in which a transition of the disease from the joints to the lungs took place, or, at least, in which, on the speedy cessation of rheumatism in the joints, a violent inflammation of the lungs supervened, and terminated fatally. We have also seen such a metastasis to the lungs, which was removed by vigorous treatment. The venerable Dr. Haygarth, however, has given a more unfavourable statement of this matter from his experience; for "out of 170 cases," (speaking of acute rheumatism,) he says, "I have found twelve which had a fatal termination, either by a transition of the inflammation to the brain, lungs, kidneys, stomach, or some other vital part, or as being found in combination with other diseases." (See Clinical Hist. of Acute Rheumatism, p. 61.) Dr. Cullen has not mentioned any such result of the disease. From the observations of our contemporaries, it has been found that the heart is peculiarly liable to be affected by a metastasis of rheumatic inflammation, or to be attacked with a slow disease, by which its bulk becomes increased, and its functions disturbed, after

the cessation of acute rheumatism. This fact was first mentioned by Dr. Baillie, on the authority of the late Dr. Pitcairn, and has since been more fully established by the records of several cases. See especially a paper by Mr. Ferjeant-furgeon Dundas, in the first volume of the Medico-Chirurgical Transactions; also Dr. Baillie's Morbid Anatomy.

It has been remarked by Dr. Cullen, as indicative of the peculiar nature of rheumatic inflammation, that "the acute rheumatism, though it has so much of the nature of the other phlegmasia, differs from all those hitherto mentioned in this, that it is not apt to terminate in suppuration. This almost never happens in rheumatism; but the disease sometimes produces effusions of a transparent gelatinous fluid into the sheaths of the tendons. If we may be allowed to suppose that such effusions are frequent, it must also happen that the effused fluid is commonly re-absorbed; for it has seldom happened, and never indeed to my observation, that considerable or permanent tumours have been produced, or such as required to be opened, and to have the contained fluid evacuated. Such tumours, however, have occurred to others, and the opening made in them has produced ulcers difficult to heal." (See Cullen, First Lines, par. 448.) The non-occurrence of suppuration in these violent rheumatic inflammations is of itself a striking characteristic of the disease; and the circumstance, that it is not productive, on the other hand, of what are called *chalk-stones*, or of that cretaceous-like secretion which is the result of the inflammation of gout, distinguishes it from the latter malady. In addition to this circumstance, however, there are other points of distinction between the *gouty* and *rheumatic* inflammation; namely, that the latter usually attacks the large joints; that it is not preceded by symptoms of indigestion; that it does not recur in regular paroxysms; and that it attacks younger people, and those not liable to gout from their modes of life; and, as we shall see immediately, is usually the effect of a specific cause, cold.

*Causes of Acute Rheumatism.*—The circumstances which constitute a predisposition to the attacks of acute rheumatism are various. Persons of an irritable, plethoric, or sanguineous habit, are most liable to be affected, when exposed to the action of the exciting causes; and a certain period of life, in which there is a considerable vigour in the sanguiferous system, also predisposes to it. It affects, indeed, persons of all ages, from five to above sixty years; but is much the most frequent between the time of puberty and the thirtieth year. Dr. Haygarth considers it as most common between fifteen and twenty. Some difference has been supposed to exist with respect to *sex*; since it is certain that males are much more subject to the disease, in this country, than females; Dr. Haygarth says, in the proportion of nearly four to three. But it is probable, as the same writer suggests, that this arises from the more constant exposure of men to cold and rain, by the nature of their occupations, than women; whence, he was informed, that, in Holland, the rheumatism is seldom found in women, though the air is very humid, because they are more domesticated than in this country, and their dress is warmer. Preceding attacks of the disease seem to afford a strong predisposition to future recurrences of it.

When these predispositions exist, the acute rheumatism is readily excited by the sudden application of cold or damp, when the body has been already much heated, and is perspiring after fatigue; or when one part of the body is exposed to cold, while the other parts are kept warm; or, lastly, by any long continued application of cold and moisture, under any circumstances, as by wearing wet or damp

## RHEUMATISM.

clothes. Whence the disease is almost exclusively observed in cold and changeable climates; and is most frequent in the most variable seasons, as in the spring and autumn, very seldom occurring during the steady heat of summer.

*Cure of Acute Rheumatism.*—With respect to the treatment, which is most successful in the removal of this distressing and painful malady, considerable difference of opinion, and some fluctuations of opinion, have taken place among professional men. The acute pain, the great heat, the quickness and fullness of the pulse, and the buffy or inflammatory appearance of the blood, when drawn, have led the majority to look upon it as a highly inflammatory disease, and to be cured almost exclusively (like the other organic inflammations) by copious blood-letting. Boerhaave maintained this doctrine; and Cullen followed him to the full extent. "The blood ought to be drawn in *large quantity*," says the latter, "and the bleeding is to be repeated in proportion to the frequency, fullness, and hardness of the pulse, and to the violence of the pain. For the most part, *large and repeated bleedings*, during the first days of the disease, seem to be necessary, and accordingly have been very much employed; but to this some bounds are to be set: for very profuse bleedings occasion a slow recovery, and, if not absolutely effectual, are ready to produce a chronic rheumatism." (First Lines, parag. 463. See Boerhaave, app. 1493.) The Cullenian doctrine is, we believe, even now taught in the school of Edinburgh, with scarcely any of the cautionary bounds mentioned by that sagacious practitioner. Sir John Pringle trusted much to the same practice. Sydenham began his career by ordering four bleedings for the cure of rheumatism; but he appears to have gradually declined in his attachment to that practice, and says, that he found it better to purge after the second bleeding. And again, in the last piece which he ever wrote, he says, "If we obstinately persist in these evacuations, till the symptoms entirely go off, the disease will often terminate fatally." (Sched. Monitor.) He also says, in his *Processus Integri*, which he composed for the use of his son, that in young persons, who live temperately, "the rheumatism may be as successfully cured by a very cooling and moderately nourishing diet, as by repeated bleedings, which they cannot so well bear." Van Swieten, who has traced out this progress of Sydenham's experience, admits that he has cured many cases of acute rheumatism without bleeding, if they were mild in the beginning.

Now this has been the progress of the general experience in our own times; and at present, few English physicians deem blood-letting the leading remedy for acute rheumatism. On the contrary, the most experienced have fully decided, that, in the great majority of cases, evacuation is entirely unnecessary; and that, if it is frequently repeated, it does a material injury, by sinking the patient into a long and tedious chronic disease, as Dr. Cullen stated, from which there is sometimes no recovery; and always occasions a lingering convalescence. Perhaps the only cases in which it is requisite are in persons of highly vigorous and inflammatory habits, in whom a single bleeding may diminish that diathesis; and in those cases in which metastasis threatens, or actually takes place. Where this translation has indeed already occurred to any vital organ, as the lungs or brain, then the most vigorous venesection must be resorted to, as for the most dangerous forms of pleurisy or phrenitis.

But, we repeat it, experience has legitimately proved, that blood-letting may be superseded altogether, in a great majority of cases of acute rheumatism, by other remedies. These other remedies, to which different practitioners have resorted, have been chiefly *purgatives*, *sudorifics*, *opiates*, and

the Peruvian *bark*, of each of which it will be necessary to take some notice; for they are all useful under certain conditions of the patient and the disease, and constitute the principal means of cure.

*Purgatives*, as they contribute, if properly selected, to reduce every species of febrile excitement, though they are alone incapable of effectually relieving this disease, are yet essentially beneficial as a part of the plan of cure. The saline purgatives, such as the sulphate of magnesia, are the best adapted to relieve the bowels and the system at large; or they may be assisted by moderate doses of calomel, which perhaps more effectually empties the upper bowels. They become also more particularly necessary, when the narcotic medicines, to be mentioned presently, are administered, with a view to obviate the constipation which the latter produce. But no practitioner would confide in cathartics alone for the cure of acute rheumatism.

With respect to *sudorifics*, there is a more general tendency to trust the cure to them; partly because the pains are often said to be easier, while perspiration is present; and partly with the view of assisting the apparent efforts of the constitution. It may be remarked, however, that although the most profuse sweats very frequently break out spontaneously, they seldom afford any essential relief; and they will continue day after day, without any apparent influence upon the disease. Accordingly, much direct benefit could not in reality be expected to arise from augmenting a discharge, already very profuse, and of considerable duration; and, in truth, we believe mere sweating is productive of no benefit. But the medicines given as sudorifics, especially antimonials and Dover's powder, operate beneficially perhaps by their other qualities. Thus the antimonials, and the ipecacuanha, and salt of this powder, are kindly and gentle laxatives, and thus produce an antiphlogistic effect as evacuants; but the principal operation of the powder of Dr. Dover is probably the result of the opium which it contains.

For *opiates* alone, that is, uncombined with antimony or ipecacuanha, have been relied upon by some practitioners, and with the most marked success. As opium, and other substances, possessing a similar narcotic power, have been known from ancient times to be highly stimulant, that is, to cause an increased activity and vigour in the circulation and nervous system, and therefore to be highly injurious in active inflammations; so all those physicians, who advocated venesection, shunned the use of opiates religiously; and even those, who found by experience that blood-letting was not required, questioned nevertheless the impunity with which opiates might be administered. Experience, however, has now fully determined this point also; that opium may be administered largely, not only with safety, but with most essential benefit, in the most severe cases of acute rheumatism. As far as our own observation has gone, indeed, (and we have had occasion to treat some hundreds of persons affected with this malady,) the combination of repeated doses of opium, with a daily saline laxative, with copious thin diluent drinks, and a light diet, in the beginning of the disease; a practice which, it is but justice to say, was introduced into St. George's hospital, many years ago, by the present senior physician, Dr. George Pearson. From half a grain to a grain, or more, of solid opium may be given three times a day, in the combination just mentioned, without affecting the head or the stomach, with great, speedy, and often permanent relief to the disease, and without leaving the tendency to a slow convalescence, or a chronic malady, like the violent depletory system.

## RHEUMATISM.

In favour of the treatment of this apparently acute inflammation by the still more opposite means of a powerful tonic, the *cinchona*, or *Peruvian bark*, the recorded testimony is still more considerable. Dr. Cullen affirmed of the bark, that he had "seldom found it useful, and in some cases hurtful," when employed before the phlogistic diathesis was abated, and something like remissions occurred in the fever. Other practitioners, however, have considered these previous changes unnecessary, except in a very partial degree, and contend, that the early use of the bark is the most efficacious mode of curing acute rheumatism. Dr. Haygarth is one of the most strenuous advocates for this practice; indeed, a conviction of its advantages is the avowed motive for the publication of his "Clinical History" of the disease, to which we have already referred. He was led to the adoption of the remedy early, on the recommendation of the celebrated Dr. Fothergill, who received it from Sir Edward Hulse. Dr. Haygarth has recorded eighty-four cases in which the cinchona was administered, in general, very early in the disease, after a moderate evacuation of the stomach and bowels, principally by means of antimonial medicines. On some occasions, however, Dr. Haygarth also preceded the use of this remedy by a bleeding, where the symptoms were very violent.

On the whole, the inference which we are disposed to draw from these authorities, aided by personal observation, is, that the most successful practice consists in a free purgative evacuation, and an occasional bleeding in particular habits, in the very onset of the disease, followed immediately by the free use of opiates, with copious drinks and saline laxatives, and this succeeded, without delay, when the pains and tumours have somewhat remitted, by a resort to the decoction of cinchona, or some gentle tonic.

All external applications to the parts which are swelled and painful, in acute rheumatism, are of little or no service. The warm bath and fomentations, especially in the beginning of the disease, rather aggravate than relieve the pains. Blistering, or the minor degree of superficial inflammation produced by rubefacients, if they diminish the pain in one part, generally only occasion it to shift to another, and do little towards the cure of the general affection. The same observation is applicable to refrigerant remedies, such as to washing with cold water or other lotions the tumid joints; the disease but changes its station, without any tendency to cease altogether; and the change of situation, though it is commonly from joint to joint, may nevertheless occasionally take place from the joints to a more important organ.

**RHEUMATISM, Chronic.** In many instances, this form of rheumatism is the direct consequence of an attack of the acute form of the disease. The febrile symptoms, the swelling, and particularly the redness of the joints, have disappeared, and the general functions have resumed their healthy condition; but still certain joints continue to be affected with pains and stiffness, which are particularly felt on motion, and are often accompanied by a spontaneous coldness, and a torpor, sometimes almost amounting to paralytic. These affections are much influenced by the changes in the temperature and humidity of the atmosphere, and are distinctly aggravated by external cold, and relieved by external warmth. The parts affected are not easily made to perspire, and when the other parts of the body are brought into a state of free and warm perspiration, that on the pained joints is only cold and clammy. The pains are also, like those of acute rheumatism, most severe in the night.

This chronic affection of the joints, however, is very often altogether independent of any previous inflammation and swelling, and occurs in many persons who have never been subject to an attack of acute rheumatism. It occurs, indeed, very frequently in persons somewhat advanced in life, and beyond the period when the acute form of the malady is usually seen. In these cases it is commonly ascribed to the action of cold; very often to partial exposures of the particular parts of the body in which it takes its seat; and it is apt to be produced again and again in those parts which have once suffered from exposure of other parts of the body to cold. Thus, getting the feet wet will induce an attack of lumbago, sciatica, or a crick in the neck, according to the predisposition induced in these respective regions by former attacks. Many cases of chronic rheumatism are ascribed, however, to violent strains of the muscles of particular parts, occurring on sudden and somewhat violent exertions, and even to fatigue from long continued exertions of particular muscles.

As the exact nature of the affection called chronic rheumatism is not very clearly understood, so the method of cure, which is usually pursued, is somewhat empirical; *i. e.* the mere result of the observation of the effects of different medicines which have been tried. Dr. Cullen, indeed, attempted to explain the nature of the disease, by saying, that it consisted in "an atony both of the blood-vessels and of the muscular fibres of the part affected, together with a degree of rigidity and contraction in the latter, such as frequently attend them in a state of atony;" and therefore concluded, that such remedies were required, as were suited "to restore the activity and vigour of the vital principle in the part." The explanation of Dr. Bardley, however, though not very different, is perhaps more consonant to the general opinion upon this subject. He considers the principle of cure as simple and uniform; namely, that "it consists in removing passive inflammation, and restoring the debilitated vessels and muscular fibres to their due tone and action." (See Dr. Bardley's Medical Reports, p. 4.) The remedies by which these objects are attained, may be included under two heads, internal and external.

The *internal* remedies which have been recommended for the cure of chronic rheumatism, though very numerous, have, on the whole, been found to possess a very uncertain power over the symptoms of that disease; and many which have been highly extolled, have been given up in total disappointment. Nevertheless, in many instances, these remedies are essentially beneficial, sometimes curing the disease alone, and generally aiding the operation of external applications. They may be described under the denomination of sudorifics and stimulants, or stimulant-diaphoretics, to which may be added mercurials, and some individual articles of peculiar operation.

These sudorifics appear to possess very little remedial power over the chronic rheumatism, and the less in proportion as the disease partakes less of the swelling and inflammation of the acute species, or as it is of longer standing. In the majority of cases they are even worse than useless. Dr. Bardley says, "in short, I can speak decidedly of the injurious effects of sudorifics, when pushed to any great extent, in every instance of severe local affection of the joints; and also in most other cases, where the disease has been long continued, and the patient's constitution much debilitated. In chronic lumbago and sciatica, I have never experienced any lasting benefit to result from this mode of practice." Dr. Bardley, indeed, speaks very lightly of the effects of all the internal remedies, not only of this, but of the stimulant

lant clafs. He admits that fmall dofes of antimonial powder, combined with calomel and opium, are certainly ufeful in allaying pain and irritation; but he believes that their efficacy confifts rather in palliating fymptoms, than in curing the difeafe, when it is confiderable in degree and obftinate in kind. "The fame obfervation," he fays, "will nearly apply to the ufe of ftimulant remedies, fuch as refin of guaiacum, the clafs of terebinthines, and of effential oils. In the moft aggravated inflances of general chronic rheumatifm, where great torpor and debility prevailed, guaiacum, in fuch large dofes as the ftomach and bowels would bear, was found to be a powerful auxiliary; and certainly the moft generally efficacious of all the internal remedies that were employed. But I have feen no inflance of its complete fuccefs, when unaided by topical applications, in any fpecies of the difeafe where much local injury of the joints had taken place. It acted moft beneficially when exhibited in fubftance, well triturated with mucilage; to which was occasionally added gum kino, or tincture of opium, to prevent its effects on the bowels. In many obftinate cafes, the ammoniated tincture of guaiacum, incorporated with mucilage, and joined to a ftrong decoction of bark, proved of great fervice, where the conftitution was broken down by the violence and length of the difeafe. There were but few protracted cafes in which the Peruvian bark was not prefcribed with advantage as a tonic, efpecially at the clofe of the difeafe. It was, however, never adminiftered with any other defign than as an auxiliary." (Loc. cit. p. 16.) We have quoted this paragraph, as containing the refult of the deductions from a large number of cafes, treated in a public hofpital, by a careful and intelligent obferver; and, therefore, as affording a probable approximation to the general fact of the operation of thefe medicines. The fame obfervations, we believe, are applicable to fome of the other remedies, of a ftimulant and diaphoretic quality, which are often reforted to; fuch as the preparations of ammonia, infufion of horfe-radifh, decoctions of mezereon and rhododendron, muftard-feed, and all the terebinthinate fubftances and hot gums. The oil of turpentine itfelf has been much employed, and perhaps conftitutes a part of the celebrated noftrum called the effence of muftard; but our experience of its effects accords with that of Dr. Bardfley, who fays, that, in every form, turpentine was found to be an ungrateful medicine to the ftomach: often impairing the appetite, and not producing, when even duly perfifted in, effects as falutary as the guaiacum and other remedies already mentioned. Nevertheless, we muft remark, that in different individual inflances, one of thefe remedies will fometimes fucceed when the others have failed, and that therefore none of them fhould be excluded from the catalogue of ufeful expedients.

Some other fubftances have been employed, with occasional fuccefs, in the cure of different cafes of chronic rheumatifm, which do not appear to poffefs any quality in common, and the operation of which, therefore, cannot be fatisfactorily explained. Among thefe we may mention *fulphur*, which has long poffeffed a fort of popular reputation for the cure of lumbago, and fome other varieties of the difeafe. Taken nightly in a confiderable dofe, fo as to act gently upon the bowels, it has fucceeded, in fome inflances, in affording a very fpeedy and marked alleviation of the fymptoms; but, on the other hand, it has very often failed to produce any effect whatever; and under what circumftances thefe refpective variations in its operation occur, we have not been able to afcertain. Another remedy has enjoyed a very high reputation in fome parts of the country, efpecially in Lancafhire; we mean the *cod-liver oil*, or *ling-liver oil*; for it appears that the oil obtained from the liver of either of thefe fifh is equally effica-

cious. Of this remedy many teftimonies might be adduced in proof of its occasional efficacy in the moft unyielding cafes of chronic rheumatifm. From long and repeated experience, Dr. Bardfley affirms that he is enabled to fpeak of it as a medicine of confiderable but limited powers: in fome inflances, where every other means had proved unfuccefsful, it has operated in a manner fo decidedly beneficial, as to excite aftonifhment; but, on the other hand, he found it to fail often in the more mild and common rheumatic affections. He believes it to be moft beneficial in the chronic rheumatifm of perfons advanced in age, which is accompanied with extreme rigidity of the mufcles, and inflexibility of the joints, in confequence of much exposure to cold and moifture, with hard fare and much fatigue. It was commonly taken in warm table-beer by the hofpital patients, in dofes of half an ounce, or from that to an ounce and a half twice or thrice a day, according to its effects, or to its agreement with the patient's ftomach. Its operation is various, fometimes upon the kidneys, and fometimes upon the bowels; and occasionally it produced an eruption on the fkin: but thefe effects occurred only at the firft taking; for after a fhort continuance, it ceafed to produce any fenfible operation. When it produced relief, this was obvious by the end of a fortnight, and continued flowly to increafe; and in thefe cafes the patients generally began to increafe at the fame time in bulk and fatnefs. Nevertheless, the objections to the general ufe of this medicine, from its extremely naufeous fmell and tafte, which render it abfolutely intolerable to many ftomachs, however difguifed, and the admiffion of Dr. Bardfley, that it is only to be deemed an auxiliary, and in many refpects inferior to guaiacum, do not lead us to expect that it will ever be generally adopted, notwithstanding its reputation and extenfive employment in the Manchester Infirmary, where the annual confumption has been nearly fixty gallons for about forty years. Bardfley, loc. cit. p. 22.

As another expedient for the cure of chronic rheumatifm, the *arfenical folution* of Dr. Fowler has been recommended by Mr. Jenkinson and others. For our own part we have not been fo fortunate as to difcover any remedial properties of this fort in that folution; but from the evidence of two or three cafes adduced by Dr. Bardfley, it appears probable that this medicine is capable of producing very beneficial effects in protracted chronic rheumatifm, where the vital powers are much diminiſhed, and the ends of the bones, periosteum, capſules, or ligaments of the joints, are likewife partially affected; though in the milder cafes, where the mufcles and their inveſting membranes are the feat of the complaint, it appears to be ufelefs.

*External Remedies.*—Among the remedies which are ufually employed externally for the cure of chronic rheumatifm, and which, when aided by the adminiftration of medicines internally, have been found moft fuccefsful, are principally the *warm and vapour bath*, and various *epiſpafmic, rubefacient and ftimulant* plafters, liniments, and embrocations, employed with or without confiderable *friction*.

The *warm or tepid bath*, from the temperature of 85° to 95° of Fahrenheit's thermometer, is very ufeful in foothering pain, and in relaxing the ftiffened joints and rigid fibres of the mufcles, efpecially in elderly patients, whofe ftrength is confiderably reduced by the length and violence of the diforder. But the ufe of a warmer bath, fo as to excite fweating, is apt to induce both local and general debility in protracted cafes, and affords but a temporary relief to the difeafe. But on the whole, the application of the *vapour* of hot water to the furface is a more efficacious remedy. Dr. Bardfley fays, "whenever the joints were found fo rigid as to be nearly immoveable, and the pains upon motion ex-

quifitely fevere, or when the mufcles had become contracted and almoft paralytic,—and indeed in every protracted cafe of the difeafe of the hip-joint, *lumbago*, or *ſciatica*, the vapour of hot water, locally and properly applied, afforded (eſpecially in conjunction with other topical applications) a ſafe and often ſucceſſful remedy.” It may be neceſſary to deſcribe the mode of employing this vapour. It conſiſts in conveying the ſteam, from a boiler, through tubes of different diameter, ſo as to apply it to the different parts of the body. In all obſtinate affections of the joints, the author juſt quoted obſerves, a pipe of nearly half an inch in diameter is to be preferred, and a quarter of an hour is the ſhorteſt period for its application. In the commencement, however, it is better, as a general rule, to uſe a pipe of ſmaller ſize, and only to permit the vapour to ſtrike upon the affected part at ſome diſtance from its aperture; for by theſe means an inconvenience will be avoided, which has ſometimes prevented the ſteady application of the remedy; namely, a conſiderable irritation of the ſkin from an exceſs of heat. By degrees the parts become able to bear a large column of vapour, at a very ſmall diſtance from the extremity of the pipe; and thus the remedy will be moſt likely to produce its full effect. This effect, however, is generally only to be deemed auxiliary, at leaſt in obſtinate caſes; for it will ſeldom alone accompliſh the cure.

Among the epifpaſtic applications, *bliftering* is commonly reſorted to, and often with conſiderable benefit, eſpecially when the pains appear to be ſeated only in the fascia and ſuperficial fibres of the mufcles. A repetition of blifters is preferable on the whole, both as productive of leſs diſtreſs to the patient, and more benefit to the diſeaſe, to the practice of keeping the blifter open by a ſtimulating ointment. Some authors have recommended *iſſues* in preference to blifters, where they could be applied without inconvenience. The excitement of an external inflammation, by the application of the ointment of *emetic tartar*, has been alſo employed inſtead of bliftering; and in ſome caſes its effects have been highly beneficial.

*Rubefacients*, or thoſe ſubſtances which ſtimulate the cutaneous veſſels, and excite a redneſs of the ſurface by cauſing them to be diſtended with blood, have been found by the experience of all ages to be capable of removing ſlight inſtances of chronic rheumatism, and of alleviating the more ſevere, eſpecially when their operation was aided by *friction*, and by warm or ſtimulant plaiſters. Where the pains are local and permanent, that is, not liable to ſhift about from joint to joint, great advantages reſult from ſtimulating the ſkin with an active liniment, and ſupporting the excitement by means of a warm plaiſter. The liniments may be compoſed of any ſtimulant, oleaginous, ſpirituſous, or ſaponeaceous liquids: as the common liniment of ammonia and oil, the ſoap liniment, with camphor, ammonia, tincture of cantharides, or turpentine; and the plaiſters may be compoſed of the gum reſins, eſpecially ammoniacum, with the acetic acid, or vinegar of ſquills, turpentine, plaiſter of cantharides, &c. Dr. Ferriar’s formula, which is borrowed from Dr. Home, and conſiſts of two drachms of camphor, with an ounce of baſilicon, and half an ounce of black ſoap, is ſaid by him to have been very efficacious in the relief of *lumbago*. Theſe liniments ſhould be diligently rubbed upon the parts affected, after the ſkin has been warmed and irritated by the friction of hot, dry, and coarſe cloths, or the application of the fleſh-bruſh; or, eſpecially in *ſciatica* and *lumbago*, during the expoſure of the part to the vapour-pipe. By theſe methods the ſtimulating effects of the liniments are much increaſed, the pain is more effectually relieved, and the cure much accelerated; eſpecially

when a warm plaiſter is added to keep up theſe effects. (See Bardeſley, loc. cit; and Ferriar’s Med. Hiſt. and Reflections, vol. i. p. 186.) The liniment originally employed by Dr. Home was ſpread upon leather, and applied over the diſeaſed part; he ſpeaks, not only from his own experience, but from that of others who had adopted it, of the efficacy of the preſcription. (See Medical Facts and Experiments, part i. ſect. 4; and again in his Clinical Experiments and Hiſtories, ſect. 14.) His formula is perhaps more active than that of Dr. Ferriar, containing cumin ſeed and ammonia in addition to the camphor, oil of turpentine, and common black ſoap. But the diſpenſatories abound with formulas for the compoſition of ſtimulating liniments and plaiſters of ſimilar powers.

Among other ſtimulants which have been employed for the cure of chronic rheumatism, eſpecially in thoſe caſes which are obſtinate and of long duration, or are accompanied by conſiderable torpor and rigidity, and a diminution of the vital heat, the influence of the *electric* and *galvanic* fluids has been referred to; and many teſtimonies might be adduced in proof of the beneficial operations of both theſe agents. Dr. Bardeſley affirms, that the application of electricity by ſparks and ſhocks, eſpecially the former, was manifeſtly advantageous; at the ſame time he acknowledges, that it was chiefly in conjunction with the local application of vapour, and with tonics and anodynes, adminiſtered internally, that the moſt marked advantages were produced. For our own part, we have witneſſed ſo little decided effect from the operation of electricity in any diſeaſe whatever, that, after a long and frequent uſe of that agent, we have given it up in deſpair. Where it produces any effect at all, it is probably by its operation upon the mind of the patient, upon the ſame principle as the *metallic traſtors* occaſionally alleviated pain, (ſee IMAGINATION, *Influence of, on the Body*;) and not from any ſpecific operation upon the diſeaſed mufcles.

The operation of mere *friction* aſſiduouſly employed, either by means of flannel or rough cloths, of the fleſh-bruſh, or ſimply of the hands, or that ſort of rubbing or kneading of the body which is called *champoing*, have been often reſorted to with conſiderable benefit, eſpecially in the caſes connected with a paralytic torpor and rigidity of the parts affected. Perhaps, indeed, it is the ſtimulus of the friction, to which much of the benefit of liniments and embrocations ought to be aſcribed; but as the patient’s faith is chiefly fixed upon *medicated* frictions, ſo it is generally neceſſary to preſcribe them, in order to enſure his perfeverance in the rubbing.

The preceding obſervations have been applied to rheumatism generally, with only occaſional references to the particular forms under which it occurs, ſuch as *lumbago*, *ſciatica*, *pleurodyne*, rheumatic head-ache, &c. becauſe the treatment is generally applicable to the different ſituations of the body in which the diſeaſe ſeats itſelf. The principal attention that is requiſite to theſe varieties ariſes from the reſemblance of the ſymptoms to thoſe of ſome other diſeaſes. Thus the *pleurodyne*, or rheumatism affecting the mufcles of the cheſt, and the diaphragm, being accompanied with acute pain and difficult reſpiration, might be confounded with pleuriſy, and erroneouſly treated: but in this rheumatic affection of the cheſt there is ſeldom any cough, and no fever, two ſymptoms which are neceſſarily preſent in the caſe of pleuriſy. Again, the *lumbago* is apt to be miſtaken for *nephralgia*, or pain in the kidneys, connected with inflammation in theſe organs, or with the preſence of gravel in them or in the ureters: it may be diſtinguiſhed, however, from the diſeaſes of the kidneys, by the circumſtances, that the pain does not follow the courſe of the ureters, but ſtretches

stretches rather down the thighs to the toes; that it is chiefly severe on assuming the erect posture; and that it is not accompanied by sickness or vomiting; and that the urine is not changed in quantity or quality. Dr. Home, and some others, have believed that the sciatica is seated in the great sciatic nerve, or in its sheath, and the lumbago in the lumbar nerves.

*Of Arthritis rheumatica, or rheumatic gout.* This term, though improper, and calculated to mislead us in our notions respecting the nature of the disease, is retained in consequence of the want of a more correct appellation. The disease, in fact, is not a compound of gout and rheumatism, but probably rheumatism resembling, in some respects, the gout in its appearances. It has been called, by an able teacher at a large hospital in Southwark, the *rheumatagra*, or *acuto-chronic* rheumatism. In some cases, the disease is merely a partial degree of acute rheumatism, affecting only one or two of the smaller joints, as the wrist or even the knuckles, with swelling, redness, and acute pain. This is often called gout; but as it occurs under circumstances which differ materially from those under which gout appears, is not preceded by indigestion, and does not terminate in the formation of chalkstones, it is obviously a different disease. In many cases, however, it is the consequence of acute rheumatism, in which the joints last occupied by that disease, especially the ankles and wrists, remain swelled, stiff, and painful, and sometimes œdematous, for many weeks. The pain, in these cases, is generally aggravated at night, or by external heat; but it is accompanied by very little or no feverishness.

The more acute cases require nearly the same treatment as is employed for the cure of acute rheumatism. But when they assume more of a chronic form, when the ligaments and membranes of the joints are the peculiar seat of the disease, or an enlargement of the extremities of the bones appears to have taken place, especially in young or vigorous subjects, the first attempts to relieve should be made by means of *local bleeding*, either by the application of leeches, or, what is perhaps preferable, by the operation of cupping and scarifying. These local evacuations should be repeated, if the pain and irritation are not materially relieved; and the good effects may be aided by the application of *blisters* over the affected joints. Dr. Bardley strongly recommends the opening of a drain from the parts by means of *issues*, made by caustic; and affirms that, in obstinate cases, which have resisted all other means, he has found the happiest effects from issues. The *tepid bath* will often aid the operation of these remedies, together with the use of mild diaphoretics, followed by tonic bitters, such as the Peruvian bark, chalybeates, the myrrh mixture with steel, and the occasional use of antimonials with calomel.

*Nodes of the Joints.*—Before we conclude the subject of rheumatism, it seems necessary to notice a state of the joints which is generally deemed rheumatic. Dr. Haygarth, however, observes, that it is nearly allied to gout in its character, and in the persons whom it attacks. These *nodes*, which occur most commonly about the fingers, hands, and wrists, but occasionally also on the knees, ankles, feet, elbows, shoulders, and other joints, produce strange distortions of the parts, twisting the fingers, &c. in various directions, and rendering the joints almost immovable. They are not separate tumours, but feel as if they were an enlargement of the bones themselves. Dr. Haygarth, indeed, is of opinion, that the ends of the bones, the periosteum, and the capsules or ligaments which form the joints, are the seat of this disease; though he does not appear to have ever examined the matter anatomically. In bad inveterate cases, he believes

that the joints are not merely distorted, but dislocated. The swellings are generally painful, especially in the night, though not severely, and often sore to the touch. In a few patients, a crackling noise is perceived in the joints when moved, particularly in the neck. The skin is seldom, if ever, affected with inflammation. There is one distressful circumstance belonging to this disease, that it has no intermission, and but slight remissions: for during the remainder of the patient's life, the nodes gradually enlarge, impeding more and more the power of motion. The malady also spreads to other joints, without producing any alleviation in those which it had previously attacked. In one case, mentioned by Dr. Haygarth, the fingers, wrists, knees, ankles, elbows, shoulders, neck, and hips, were all affected with this disease at the same time, that is thirteen joints, exclusive of the numerous joints of the hands: if each individual joint of the hands had been taken into the account, they would have amounted to not less than forty. In this case, the malady had been rapidly advancing for ten years: yet, though these nodes, in their gradual progress, sadly embitter the comforts, they do not shorten the duration of life: for Dr. Haygarth's first patient lived to the age of ninety-three. From the experience of this veteran physician it appears, that women are much more frequently the subject of nodosity at the joints than men, and that it commonly first begins to shew itself about the period of the cessation of the menses.

Various remedies have been recommended for the relief of these nodes; but they have not been found in general to be possessed of much efficacy. On the whole, the warm bath, a stream of warm water, such as the Bath pumping, or a warm *douche* on the nodes, together with the repeated application of leeches, appear to be productive of the most decided benefit in this disease; and the use of the leeches appears to constitute a very important part of that practice. In bad cases, from four to ten should be applied to the affected joints once or twice a week. The temperature of the pumping and *douching* should be varied, and that which appears, from the patient's report, to agree the best, and to be productive of the most decided effect in alleviating the pain and swelling, and in improving the power of motion in the joints, should be adopted. This will be found to vary, in different persons, from 81 to 113 degrees of Fahrenheit's thermometer.

Some authors have conceived that, together with these external remedies, the use of soda, or the vegetable alkali, internally, has been attended with considerable benefit. And Dr. Bardley relates a case, in which the continued use of mercury, so as to excite a moderate ptyalism, was apparently remedial. See Haygarth's Clinical History of Diseases, pt. ii.; and Bardley's Reports.

**RHEXIA**, in *Botany*, derived from  $\rho\eta\chi\epsilon\iota\varsigma$ , a rupture, or fracture, is the synonym in Pliny of a plant, reputed to be endowed with numerous virtues, and, amongst others, with the powers of curing ruptures, or similar complaints. His description leaves us in no doubt as to his plant; so far, at least, as its being of the Alkanet tribe, a species of *Anchusa*, or perhaps of *Echium*. Why Gronovius and Linnæus chose this name for the present elegant American genus, does not appear.—Linn. Gen. 187. Schreb. 249. Willd. Sp. Pl. v. 2. 301. Mart. Mill. Dict. v. 4. Ait. Hort. Kew. v. 2. 340. Pursh v. 1. 257. Juss. 330. Lamarek Illustr. t. 283. Gærtn. t. 112.—Class and order, *Obandria Monogynia*. Nat. Ord. *Calycanthemæ*, Linn. *Melastomæ*, Juss.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, tubular, oblong, swelling in the lower part; limb four deep, acute segments, without any intermediate teeth or scales; permanent. *Cor.*

Petals four, roundish, spreading, inserted into the calyx. *Stam.* Filaments eight, thread-shaped, inserted into the calyx, longer than its limb; anthers declining, furrowed, linear, obtuse, versatile, with a curved beak. *Pist.* Germen roundish, superior, unconnected with the tube of the calyx; style simple, the length of the stamens, declining; stigma oblong, obtuse. *Peric.* Capsule roundish, of four cells and four valves, within the body of the calyx, but unconnected with it. *Seeds* numerous, roundish. *Receptacles* four, attached to the central column.

*Eff. Ch.* Calyx with four permanent simple teeth. Petals four, inserted into the calyx. Anthers declining, beaked. Capsule of four cells, within the body of the calyx.

*Obs.* For the difference between this genus and OSBECKIA, see that article.

Willdenow has 17 species of *Rhexia*, but we have not the means of correctly ascertaining the generic characters of all of them. They are divided into two sections, of which the following examples may suffice.

Section 1. *Leaves sessile.*

*R. virginica.* Virginian *Rhexia*. Linn. Sp. Pl. 194. Willd. n. 1. Ait. n. 1. Curt. Mag. t. 968.—Leaves sessile, lanceolate, three-ribbed, with fringe-like teeth. Calyx fringed with glands.—Native of watery places in North America, flowering in July and August. It succeeds tolerably with us, in a bog bed, with plenty of water, but requires shelter in winter; nor is it fit for general cultivation; which is much to be regretted, considering the great beauty and singularity of the large crimson flowers, with their great yellow curved anthers. The root is fibrous, perennial. Stem herbaceous, erect, square, with membranous angles. Leaves strongly ribbed, smooth, with acute slender teeth. Panicle forked, spreading. Calyx brown, besprinkled with hairs, whose points are glandular and viscid.

*R. mariana.* Maryland *Rhexia*. Linn. Sp. Pl. 491. Willd. n. 2. Ait. n. 2. (Lyfimachia non papposa, terræ marianæ, &c.; Pluk. Mant. 123. t. 428. f. 1. Lamarck, f. 1?)—"Leaves sessile, lanceolate, three-ribbed, fringed with soft hairs. Hairs of the calyx stellated."—Found in bogs, and sandy woods, near waters, from New Jersey to Carolina, flowering in July and August. From one to three feet high. Flowers handsome, either purple, light red, or pale. *Pursh.*

Section 2. *Leaves stalked.*

*R. glutinosa.* Viscid Shrubby *Rhexia*. Linn. Suppl. 216. Willd. n. 8.—Leaves stalked, opposite, elliptical, three-ribbed, smooth. Stem shrubby. Flowers in terminal, dense, forked panicles. Calyx smooth.—Found in New Granada by Mutis, who sent fine dried specimens to Linnæus, along with an Indian-ink drawing, cited in the Supplement as a published work. The whole plant is very handsome, quite destitute of pubescence, but the calyx, and upper side of the leaves, are extremely glutinous. The leaves are rather above an inch long, with three ribs, united above their base; the under side pale and yellowish. Flowers copious, large, purple.

*R. inconstans.* Stitch-leaved *Rhexia*. "Vahl. Ecl. v. 1. 37." Willd. n. 13. (Osbeckia ornata; Swartz Ind. Occ. v. 2. 647.)—Leaves ovate, clothed with depressed bristles; pale and three-ribbed beneath. Panicle forked, of few flowers. Calyx rough with spreading bristles.—Native of elevated situations on the mountains of Guadaloupe, Nevis, Montserrat, St. Kitt's, &c. among mosses.—The stems are a foot or two high, erect, branched, rigid, square and bristly. Leaves ovate, a quarter of an inch long, their green convex upper side most elegantly clothed with strong, depressed, yellow bristles, as if stitched with gold thread. Flowers purple, usually five-cleft.

*R. aquatica.* Marsh *Rhexia*. Swartz Ind. Occ. v. 2. 650. Willd. n. 16. Ait. n. 3. (Melattoma aquatica; Aubl. Guian. v. 1. 430. t. 169.)—Leaves opposite, heart-shaped, minutely crenate, nearly smooth. Panicles terminal, three-forked, slender, widely spreading, many-flowered.—Native of watery places in Guiana and the West Indies.—Stems shrubby, a yard high. Leaves flat, above an inch long, pointed. Flowers copious, rather small, white, with purple stamens. Calyx smooth.

RHEXIA, in *Gardening*, contains plants of the hardy, herbaceous, perennial kind, of which the species cultivated are; the Virginian *rhexia* (*R. virginica*); and the Maryland *rhexia* (*R. mariana*).

*Method of Culture.*—These plants may be increased by sowing the seeds procured from their native situations, in the autumn or spring, in pots filled with good fresh mould, placing them under the protection of frames, or if in a mild hot-bed they will be rendered more forward. When sown at the latter season, the plants seldom appear the same year. When the plants have attained sufficient growth they should be planted out partly in a dry sheltered east border and partly in pots, to have the protection of a frame against the frosts in winter. They flower the second year, and with care continue three or four.

And they may be introduced, as they afford ornament, in the borders as well as among flowery potted plants.

RHEXIS, or RHEGMA, formed from  $\rho\acute{\eta}\nu\sigma\iota\varsigma$ , *rupture*, of  $\rho\acute{\eta}\nu\sigma\iota\varsigma$ , *I break*, in *Surgery*, denotes a rupture of the corner of the eye.

RHHENZABERN, in *Geography*, a town of France, in the department of the Lower Rhine; 8 miles S.E. of Landau.

RHIBII, in *Ancient Geography*, a people of Scythia, on this side of the Imaus, near the river Oxus, to which belonged the town of Dauba. Ptolemy.

RHIGIA, a town situated in the interior of the eastern part of Hibernia, near Rhæbe, according to Ptolemy.

RHIME, or RIME, in *Poetry*. See RHYME.

RHINANTHUS, in *Botany*, derived from  $\rho\acute{\eta}\nu\sigma\iota\varsigma$ , *a nose*, or *snout*, and  $\alpha\omega\nu\sigma\iota\varsigma$ , *a flower*, because of its ringent corolla, compressed at the upper lip, so as to resemble the snout of some animal.—Linn. 304. Schreb. 400. Willd. Sp. Pl. v. 3. 188. Mart. Mill. Dict. v. 4. Sm. Fl. Brit. 649. Ait. Hort. Kew. v. 4. 2. Pursh 429. Michaux. Boreal. Amer. v. 2. 17. Jussl. 101. Lamarck Illust. t. 517. Gærtn. t. 54. (Pedicularis; Tournef. t. 77. Elephas; Tournef. t. 482.)—Class and order, *Didynamia Angiosperma*. Nat. Ord. *Personate*, Linn. *Pediculares*, Jussl.

*Gen. Ch.* Cal. Perianth inferior, of one leaf, roundish, inflated, compressed, four-cleft, permanent. *Cor.* of one petal, ringent; tube rather cylindrical, the length of the calyx; limb gaping, compressed at the base: upper lip helmet-shaped, compressed, emarginate, narrower; lower spreading, flat, trisid half way down, obtuse, the middle segment broader. *Stam.* Filaments four, the length of the upper lip, the two shorter ones concealed under it; anthers incumbent, cloven on one side, hairy. *Pist.* Germen superior, ovate, compressed; style thread-shaped, longer than the stamens, but standing between them; stigma obtuse, inflexed. *Peric.* Capsule obtuse, erect, compressed, of two cells and two valves, gaping at the margin; partition contrary. *Seeds* numerous, compressed.

*Obs.* ELEPHAS of Tournefort has the margin of the capsule blunt; the seeds simple; and the calyx unequal, of two lips. It was so named from the resemblance its flowers bear to an elephant's trunk.

CRISTA-GALLI of Rivinus has the margin of the capsule extended,

extended, the seeds membranous, clothed with wool; and the calyx equal, four-cleft.

Eff. Ch. Calyx inflated, compressed, four-toothed. Upper lip of the corolla compressed. Capsule of two cells, blunt, compressed. Seeds imbricated, flat.

1. *R. orientalis*. Linn. Sp. Pl. 840. (*Elephas orientalis flore magno probosceide incurva*; Tournef. Voyage, v. 2. 126, with a figure.)—Upper lip of the corolla awl-shaped, incurved.—Native of the Levant, on the confines of Persia, flowering in July.—Stems more than a foot high, hollow, square, hairy. Leaves opposite, on short stalks, notched, hairy, veined. Flowers on the upper part of the stems, fragrant, of a yellow colour, with a brown spot on the lower lip and two red ones on the upper. Tournefort reckons this a very ornamental plant.

2. *R. Elephas*. Linn. Sp. Pl. 840. (*Elephas Campolarensum*; Column. Ephr. 186. t. 188.)—Upper lip of the corolla awl-shaped, straight.—Native of shady woods in Italy, flowering in May.—This annual is very similar in habit to the last, but its calyx is trifid, with two of the segments recurved, and the third larger, erect, plaited, acute. Tournefort mentions a variety of this which he found on the coast of the Black sea.

3. *R. Crisla-galli*. Yellow Rattle. Linn. Sp. Pl. 840. Engl. Bot. t. 657. Curt. Lond. fasc. 5. t. 43. Mart. Ruil. t. 148.—Upper lip of the corolla arched. Calyx smooth. Leaves lanceolate, serrated.—Common in our meadows and pastures, flowering from June to August. Root annual, fibrous. Stem branched, smooth, frequently spotted. Leaves opposite, sessile, rough; heart-shaped at the base. Flowers somewhat alternate, on short stalks, yellow. Seeds with a membranous border. The English name has obtained, from the rattling of its seeds in the capsule.

4. *R. Trixago*. Linn. Sp. Pl. 840. (*Bartfia Trixago*; Sm. Prodr. Fl. Græc. Sibth. v. 1. 427. *Trixago apula unicaulis*; Column. Ephr. 199. t. 197.)—Calyx hairy or downy. Leaves opposite, bluntly serrated. Stem perfectly simple.—Native of Italy, the south of France, and Palestine. It flowers in May.—Root annual, but throwing out runners. Stem more than a foot high, straight, firm, square, rather woolly. Leaves long, narrow, pale green, toothed or rather jagged. Flowers in large, yellow spikes. Ray observes that the figure of Columna possibly may be a variety of this species, for it differs in a few slight particulars.

5. *R. maximus*. Willd. n. 5. Desfont. Atlant. v. 2. 34.—Lower lip of the corolla longer than the upper; segments obtuse, equal. Calyx villous. Upper leaves alternate, oblong, bluntly toothed. Stem branched.—Native of Crete. We know not of any figure of this species which is admitted on the authority of Willdenow and Desfontaines.—Stem from eighteen inches to two feet high, branched at the upper part, and downy. Lower leaves opposite. Flowers in yellow spikes at the tops of the stem and branches. This species has much the appearance of *Bartfia viscosa*, of which indeed the *R. maximus* of Lamarck is merely a variety. The same author makes the present a variety of the following.

6. *R. versicolor*. Willd. n. 6. Desfont. Atlant. v. 2. 33.—Corolla gaping; lower lip longer than the upper; segments obtuse; the middle one narrower. Calyx villous. Leaves mostly opposite, lanceolate, the upper ones toothed at the base. Stem simple.—Native of Italy and the north of Africa. This differs from the preceding, in having a simple stem. Leaves linear-lanceolate, the upper ones only toothed at the base. Bractæas ovate, acuminate. Corolla only half as large, of a purple colour, the middle segment of the lower lip narrower than the other two.

7. *R. capensis*. Willd. n. 7. (*Buchnera africana*; Linn. Sp. Pl. 879.)—Calyx downy. Bractæas ovate. Leaves lanceolate, toothed.—Native of the Cape of Good Hope. This is nearly allied to *R. Trixago*, becoming totally black in drying.—The leaves have three or four teeth on each side, the upper ones sometimes alternate. Bractæas downy, a little pointed. Calyx four-cleft, obtuse as in *Crisla-galli*.

8. *R. indicus*. Linn. Sp. Pl. 841. Fl. Zeylan. 107. Burm. Ind. 131. t. 39. f. 1.—Leaves nearly lanceolate, hairy, entire.—Native of Ceylon.—Root annual. Stem a span high, erect, simple, square, hispid. Leaves opposite, small. Flowers sessile, solitary, opposite, turned to one side.

9. *R. virginicus*. Linn. Sp. Pl. 841. Gronov. Virg. 192.—Corolla spreading at the throat. Leaves sinuated and toothed.—Native of Virginia. This plant is nearly akin to *Gerardia*, of which it is most probably a species. The anthers are rough with hairs.

10. *R. trifida*. Willd. n. 10. Vahl. Symb. v. 1. 44.—Corolla wide at the throat. Leaves trifid.—Native of sandy hills in Armenia and Galatia.—Root annual. Stem six inches high, herbaceous, ascending, quite simple, rather downy, round. Leaves opposite, sessile, downy, ribbed, deeply three-cleft. Flowers axillary, solitary, opposite, sessile.

RHINBERG, in *Geography*. See RHEINBERG.

RHINE, a river which rises in the Grison Alps in three branches, which unite into one stream. Cæsar is the most ancient author who has traced the course of this river from its source in the Alps to its discharge into the sea. According to this writer it commenced in the territory of the Lepontii; and Pomponius Mela mentions two lakes which it traverses soon after, viz. the "Lacus Venetus" and the "Lacus Aeronius." Of the descriptions given by ancient writers of this river, that of Tacitus is the most precise and satisfactory. The Rhine, says this historian, after having pursued its course in one bed, and arriving near the country of the Batavi, divides itself into two branches; one of which preserves its name and the rapidity of its course along the borders of Germany until it discharges itself into the sea; the other runs towards Gaul, in a larger channel and more tranquil state, and is called by the people of the country "Vahalis," or Wahal. But it soon changes this name for that of "Mosa," or Menfe, and blended with this river discharges itself into the ocean. Such is the account of Tacitus, to which we shall subjoin some other particulars from ancient writers. The Rhine, which, as we have said, has its source in the Alps, assumes a northerly direction, and for a considerable interval separates Gaul from Germany. At the town of "Burgenatium," or "Quadruburgium," it separated itself into two arms or branches; the one flowing northward, and the other towards the west. This last assumed the name of Vahalis (Vahal), and watered the towns of Noviomagus, Grimes, &c. united with the Mosa or Meuse, and in this confluent state discharged itself into the sea. The other branch, which ran in a northerly direction, watered Arenatium, since called Castra Herculis; at which place commenced the canal of Drusus, "fossa Drusiana." Here a new division took place; the canal of Drusus pursued a northerly course, and the bed of the Rhine was directed towards the west. This last watered, beside other places, Batavodurum, Trajectum, Lugdunum Batavorum, and emptied itself into the sea, at a place called "Castellum Romanum." We ought, however, to observe, that near Trajectum it furnished a small branch which had a northern course. The canal of Drusus flowed northwards, and it is now called the Yffel. This canal, before it reached the sea, traversed a small lake called Flevo, from which issued

a small river of the same name, which ran towards the sea in a northerly direction, and discharged itself into it near a place called "Castellum," which defended the entrance of this river. The lake just mentioned is considerably enlarged, and communicates with the sea under the name of Zuiderzee. The Rhine has been almost always regarded by the Romans as the boundary of their empire between Gaul, which they had conquered, and Germany, into which they made frequent incursions. According to modern accounts of the course of the Rhine, it commences, as we have said, in the Alps of the Grisons in three branches, which afterwards unite into one stream. The principal branch descends from the mountain of St. Gothard, and runs into the lake of Constance, near Rheineck; traversing the lake of Constance and Zell, it passes near Stein, Schaffhausen, Eglisau, Keiserstuhl, Seckingen, Rheinfelden, Bâle, Huningue, Straßburg, Spire, Worms, Oppenheim, Bingen, Mentz, St. Coar, Coblenz, Bonne, Cologne, Zons, Nuys, Duffeldorp, Duyfberg, Rees, and Emeric, a little below which a large branch separates to the left, and takes the name of Wahal; it then proceeds to Huillen and Arnheim, near which another branch breaks off to the right and joins the Issel. The stream that still maintains the name of Rhine passes on to Wageningen, and Wyck le Duerstede, where it is again divided. The larger part to the left takes the name of the Leek and joins the Meuse; the smaller and less branch passes by Utrecht, Voerden, Leyden, &c. and loses itself at last in the sand, just before it reaches the German sea, a few miles after it has left Leyden. By the treaty of Paris in 1814, the Rhine is to remain as the boundary of France and Germany, and the main stream of this river constitutes the frontier, provided however that the changes that may hereafter take place in the course of that river shall not affect the property of the islands.

RHINE is also a river of Brandenburg, which runs into the Havel, 10 miles above Havelburg.—Also, a river of France, which runs into the Loire, near Roanne.

RHINE, *Circle of the Lower*, a division of Germany, bounded by the circles of Westphalia, Upper Rhine, Franconia, and Swabia, and by the duchy of Luxembourg and France. In conjunction with the circle of the Upper, it is said to contain 960 square German miles. The states of this circle were the electors of Mentz, Treves, and Cologne, together with the Palatine, the duke of Aremberg, the prince of Taxis, the Teutonic bailiwick of Coblenz, the prince of Nassau-Dietz, on account of the feigniory of Beilstein, the elector of Treves, on account of Lower Henburg, and the count of Sinfendorf, on account of the burgraviate of Rheineck. The claim of the town of Gelnhausen was disputed. The summoning prince and director of the circle was the elector of Mentz. The diets of the circle have ever since the middle of the 17th century been held at Francfort on the Mayn. This circle was one of those called the "anterior circles," but which, in the years 1607 and 1702, formed with each other a mutual compact for defence against the attacks of an enemy. This compact continued, and the circle always appointed its quota of horse and foot; which quota, as well as the contribution of the circle to the aid of the empire, was generally equal to that of the circle of the Upper Rhine. In regard to religion, this circle was reckoned among the mixed.

RHINE, *Circle of the Upper*, was bounded by the circles of the Lower Rhine, Westphalia, Upper and Lower Saxony, Swabia, and Franconia, and by those of France, formerly called Alsace and Lorraine, in the latter of which were some lands belonging to this circle. The states belonging to this circle were the bishoprics of Worms and

Spire, with the provostship of Weissenburg, Straßburg, Bâle, and Fulda, and the commandery of the order of St. John, and also the princely abbey of Prum, with the provostship of Odenheim, and the electorate palatinate of Simmern, Lautern and Veldeuz, the palatinate of Deux-Ponts, Hesse-Cassel, Hesse-Darmstadt, Hersfeld or Hirschfeld, and Sponheim, the margraviates of Nomeny, Salm with Kirburg, Nassau-Weilburg, Nassau-Ufingen, Nassau-Idstein, Nassau-Saarbrücken, and Otweiler, together with those of Waldeck, Hanau-Munzenberg, Hanau-Lichtenburg, Solms-Hohenfolms, Solms-Braunfels, Solms-Ruddeheim, Solms-Laubach, and the electorate of Mentz on account of Königstein, that of Stolberg on account of the same, those of Henburg-Birstein, Henburg-Badingen, Wafersbach, and Mucholz, Grewiler, Grunbach, Dhaun, Leiningen-Hartenburg, Leiningen-Westerburg, and Grundstadt, Munzfelden, Witgenstein of Witgenstein, Witgenstein-Berleburg, Falkenstein, Reipolzkirchen, Creange, Wartenburg, Bretzenheim, Dachtuhl, and Ollbruck, and the imperial cities of Worms, Spire, Francfort, Friedburg, and Wetzlar. The bishop of Worms, and the elector palatinate for the duchy of Simmern, were summoning princes of this circle. The diets of the circle of the Upper Rhine were formerly held at Worms, but in the last century at Francfort; but the chancery circle of the archives belonging to it were kept at the directory at Worms. This circle, with regard to religion, was reckoned among the mixed, and to the chamber judicatory actually presented two assessors.

RHINE, *Lower*, one of the ten departments of the N.E. region of France, bounded on the N. by the departments of Mont Tonnerre and the Moselle, on the E. by the Rhine, on the S. by the department of the Upper Rhine, and on the W. by the departments of the Vosges, the Meurthe, and the Moselle, situated on the left bank of the Rhine, in N. lat. 48° 45', containing 5695 kilometres, or 288 square leagues, and 444,858 inhabitants, and divided into four districts, including 37 cantons, and 616 communes. The four districts or circles are, Wissembourg, including 113,786 inhabitants, Saverne with 78,398, Straßburg with 155,647, and Barr with 97,027 inhabitants. According to M. Haffenfratz's statement, its extent in French leagues is 30 in length, and 15 in breadth. The number of circles is 5, and of cantons 30, and its population 415,080. Its contributions to the land-tax, &c. in the 11th year of the French era, amounted to 3,609,442 francs; and its expenses, administrative, judiciary, and for public instruction, amounted to 359,740 fr. 33 cents. The capital of this department is Straßburg, and it comprehends that district which, before the revolution, was Lower Alsace. As it lies between mount Vosges and the Rhine, it is diversified with eminences and plains, producing grain, wine, fruits, tobacco, saffron, and also with forests and plains.

RHINE, *Upper*, one of the ten departments of the N.E. region of France, bounded on the N. by the department of the Lower Rhine, on the S. by Switzerland, and on the W. by the departments of the Upper Saone and Vosges, situated on the left hand of the Rhine, in N. lat. 47° 40', containing 6030 kilometres, or 280 square leagues, and 382,285 inhabitants, and divided into five districts, or circles, including 39 cantons, and 703 communes. The five districts are Colmar, comprehending 144,821 inhabitants; Altkirch, 83,515; Delemont, 35,779; Porentruy, 34,910; and Befort, 83,260. According to the statement of M. Haffenfratz, its extent in French leagues is 24 in length, and 14 in breadth: its circles are 3, its cantons are 25, and its population consists of 283,252 persons. Its contributions to the land-tax, &c. in

the 11th year of the French era, amounted to 2,837,063 fr. and its expences, administrative, judiciary, and for public instruction, amounted to 354,279 fr. Its capital is Colmar, and it is composed of Upper Alsace, Sundtgaut, Porentruy, and a part of the bishopric of Bâle. The soil is in some parts moderately fertile, and in others yields all sorts of grain, wine, and pastures. It has mines of silver, copper, lead, iron, and coal, with mineral springs.

**RHINE**, *Confederation of the*, now abolished. See CONFEDERATION, &c.

**RHINE** and *Moselle*, one of the thirteen departments of that region of France called the Reunited country, bounded on the N. by the department of the Roer, on the E. by the Rhine, on the S. by the departments of Mont Tonnerre and the Saone, and on the W. by the departments of the Sarre and the Roer; situated in N. lat. 50° 15', and formed of a part of the electorate of Treves, S. of Roer, and on the left hand of the Rhine. Its territorial extent is 4860 kilometres, or 290 square leagues, and the number of inhabitants is 203,290. It is divided into three circles or districts, including 30 cantons, and 675 communes. The districts are Coblenz, containing 69,900 inhabitants; Bonn, 70,508; and Simmern, 62,882. According to Haffenratz, its extent in French leagues is 25 in length, and 12 in breadth: it contains 3 circles, and 30 cantons, and a population of 372,000 persons. Its contributions to the land-tax, &c. in the year 11, amounted to 1,717,463 fr.; and its expences, administrative, judiciary, and for public instruction, were 239,883 fr. 33 cents. The capital of this department is Coblenz. Several tracts in it are hilly and wooded; and others, though but indifferently fertile, produce considerable crops of grain, flax, hemp, wine, fruits, and pastures. It has mines of iron, quarries of marble, stone, &c.

**RHINE**, in *Ichthyology*, a name given by Aristotle, Apian, and most of the Greek writers, to that species of the squalus, which we usually call the *squatina*: the *squatius* of Ildore and Pliny. Arledi has distinguished this from all the other species of the squalus, by the having no pinna ani, and the mouth in the extremity of the snout. See SQUALUS.

**RHINE-GRAVE**, in Germany, a count palatine of the Rhine. See GRAVE and PALATINE.

**RHINE-LAND ROD**, in *Fortification*, &c. a measure of two fathom, or twelve feet, used by the Dutch and German engineers, &c.

**RHINENCHYTES**, in *Surgery*, a fyringe for the nose.

**RHINFELS**, in *Geography*, a town and fortrefs of Germany, in the county of Catzenelnbogen, near St. Goar.

**RHINGAU**, or **RHEINGAU**, a tract of country along the Rhine, in the electorate of Mentz, extending from Baecharach to Mentz, celebrated for its excellent wine.

**RHINGAU**, in *Ichthyology*, the name given by some authors to the lavaretus, a small fish caught in the German lakes, and sent in pickle into many parts of the world.

**RHINHEIM**, in *Geography*. See REINHIEIM.

**RHINIUM**, in *Botany*, a name given by Schreber, in his Genera, 701, to the *Tigarea* of Aublet, Lamarck Illustr. t. 826; but in his addenda, 833, referred to TETRACERA; see that article hereafter.

**RHINOBATOS**, in *Ichthyology*, the name of a flat cartilaginous fish, of the *squatina* or monk-fish kind, but differing from it in this, that the body is proportionably longer, and the head is more pointed; and the mouth is a great way below the end of the snout, and placed under the head. It is from three to four feet long, and is common in the Mediterranean, and brought to market in some parts of

Naples. This is a species of ray in the Linnæan system. See RAIA.

**RHINOCEROS**, in *Zoology*, a genus of the class Mammalia and order Bruta, of which the generic character is, horn solid, perennial, conic, placed on the nose, not adhering to the bone. There are two

#### Species.

**UNICORNIS**; One-horned Rhinoceros. The one horn of this animal marks the species. It inhabits marshy places between the tropics; lives on thorns and spinous plants; it may be tamed, and becomes mild, but when enraged it will overturn trees with its violence: its sight is weak, but its hearing and smell are very acute.

In the year 1739 we had a young rhinoceros with one horn shewn in England, of which Dr. Parsons has given a very accurate account in the Philosophical Transactions, N<sup>o</sup> 470. p. 523, &c. or Abridg. vol. ix. p. 94, &c.

The creature fed on rice, sugar, and hay; his keeper used to mix the rice and sugar in the following manner: seven pounds of rice and three pounds of sugar made the provision for one day; he eat this at three meals; and besides this he eat about a truss of hay every week, and a large quantity of greens that were brought to him at different times, and of which he seemed more fond than of dried food. He drank often, and always swallowed a large quantity of water at a time.

He appeared very peaceable in his temper, and bore to be handled on any part of his body with great patience, except when he was hungry; but he was then always outrageous, as also when he was struck. His most violent passions, even on the last occasion, were however always immediately appeased by giving him victuals.

Notwithstanding the lumpish aspect and heavy make of this creature, he would jump about very nimbly in his fits of passion, and often leap to a great height; and one common mark of his fury was the striking his head against the walls, or any thing else that was in the way, and this he would do with terrible violence. He was very apt to fall into these passions in a morning, before his rice and sugar were given him, and from the whole he appeared quite untractable, and seemed able, in his passions, to have run so fast, as that a man on foot could not have escaped him.

This creature was two years old, and did not exceed a young heifer in height, but was remarkably broad and thick. His head was very large; and the hinder part of it, near the ears, remarkably elevated above the rest of the face, which was flat, and sunk down in a remarkable manner in the middle, rising again towards the origin of the horn, but in a much smaller degree.

The horn in this young animal did not rise above an inch high from its tough basis (though in full grown animals it is sometimes three feet and a half long), and was black and smooth at the top, but ragged downwards; and the determination of its growth is backward, not straight up; this is very evidently seen in the horns of old rhinoceroses, which are always curved in a considerable degree that way. If we consider the proportion of this animal's size to the length of its horn, and thence carry the proportion to that between the large horns we see in the museums of the curious, we must suppose the animal of a very stupendous size, when at its full growth.

The sides of the under-jaw in this creature stand very wide asunder, slanting outward to the lower edge, and backward to the neck; the edges turn outwards from this structure of the bones, and the head necessarily looks very large. The rhinoceros has four cutting teeth, one on each corner

## RHINOCEROS.

corner of each jaw, and six grinders in each; the first remote from the cutting teeth. That part of the head which reaches from the fore-part of the horn to the upper lip, may be called the nose: this is very thick and bulky, and has a kind of circular sweep down towards the nostrils; on all this part there is a great number of rugæ or wrinkles.

The nostrils are situated very low, in the same direction with the opening of the mouth, and not more than an inch from it; and, when viewed in a fore-view, the whole nose, from the top of the horn to the verge of the lower lip, is shaped like a bell. The under lip is like that of an ox, but the upper more like that of a horse, and he uses it as that creature does, to gather up hay from the rack, or grafs from the ground: but with this superior advantage, that this creature has a power of extending this lip to six or seven inches in length from the nose, and there drawing it to a point: with this lip, thus extended, the creature is able to grasp a stick, or any small substance, and hold it extremely fast; and this power of prolonging the lip serves, in many purposes, to the same end as the trunk of that other unwieldy animal, the elephant.

The tongue of the rhinoceros is said to be so rough as to be able to rub a man's flesh off from the hoaves; but in this young subject it was so soft, that it resembled that of a calf. It may possibly grow harder with age; but the story of its effects seems of a piece with the many other false marvels reported of this animal. The eyes are dull and sleepy, much like those of a hog in shape; he seldom opens them entirely; and it is to be observed, that they are situated nearer the nose than those of any other known quadruped. The ears are broad and thin towards the top; the neck is very short; the shoulders are thick and heavy; the body is thick, and juts out at the sides, and has a hollow in the back; the belly hangs low; the legs are short, thick, and strong; the hoofs are divided into three parts, each pointing forward; the tail is slender, flattened at the end, and covered on the sides with very stiff thick black hairs; the skin is naked, rough or tuberculated, lying about the neck in vault folds; there is another fold from the shoulders to the fore-legs, and another from the hind part of the back to the thighs. The skin is thick, and seems almost impenetrable, inasmuch that it will turn the edge of a scymitar, and resist a musket-ball; it feels like a piece of board of half an inch thick. It is covered in all parts, more or less, with a sort of incrustations, resembling scales. These are small on the neck, and largest of all on the shoulders and hips; between the folds of this thick skin, the cuticle, which is left bare, is soft and easily penetrable. The scabby incrustations of the skin have been called scales by some writers; but this is a very wrong term, for they have nothing of the nature of scales, nor any thing of regularity in them.

The creature is of the retromingent, and therefore probably of the retrogenerative kind. Those animals that have been brought to Europe have been young and small; but, according to Bontius, they equal the elephant in the bulk of their bodies, though they are lower, on account of the shortness of their legs. They inhabit Bengal, Siam, Cochinchina, Quangsi in China, and the isles of Java and Sumatra. They are fond of shady forests, the neighbourhood of rivers, and marshy places; and are fond of wallowing in the mud like the hog. The rhinoceros is a solitary animal, brings one young at a time; is quiet and inoffensive, but furious when provoked; very swift and dangerous; and, though dull of sight, has a most exquisite smell. It grunts like a hog. The flesh of this animal is eaten. The skin, flesh, hoofs, teeth, and dung itself, are used in India medicinally. The horns are in great repute as an antidote

against poison, especially those of the virgin female, called *abbada*; cups of which are said to communicate virtue to the liquor poured into them. Redi, who has been very sagacious in discovering the falsity of many of the pretended medicines taken from animals, yet gives us, on the testimony of his own experience, an account of some very remarkable virtues in the parts of the rhinoceros. The blood, he assures us, is excellent in colics and in dysenteries. The decoction of the skin, he assures us, is a grand stomachic antidote; and the horns are very valuable and alexipharmic.

This animal is the unicorn of scripture, and the Indian ass of Aristotle, who says it has but one horn.

**Bicornis**; Two-horned Rhinoceros. This species inhabits Africa, but, according to Pallas, the bones of it are found buried in the north of Russia. Its flesh resembles that of a hog; the viscera those of a horse; the second horn is shorter, and placed over the first; it has no gall-bladder, and no fore-teeth; the skin is without folds, granulated, and of a deep ashen-grey; between the legs it is smooth, and flesh-coloured; in other parts there are a few bristles, but they are most numerous about the ears and end of the tail. This animal inhabits Africa only; and seems, in its manners, to agree with the former. The mischief it does is more the effect of a senseless impulse than of rage; for, though its sight is bad, its senses of hearing and smelling are exquisite, so that the least noise or scent puts it in motion; and in running to the spot from which the alarm proceeds, it overturns and tramples on animals, or any thing else which it meets with in its way, but never stays or returns to renew the charge. There is a variety, but not often seen, that has three horns; the third being an excrescence on one of the others.

Mr. Bruce's description of the manner of feeding, as well as of some other particulars relative to the two-horned rhinoceros, seems highly worthy of notice. He informs us, that "besides the trees capable of most resistance, there are, in the vast forests within the rains, trees of a softer consistence, and of a very succulent quality, which seem to be destined for his principal food. For the purpose of gaining the highest branches of these, his upper lip is capable of being lengthened out, so as to increase his power of laying hold with this, in the same manner as the elephant does with his trunk. With this lip, and the assistance of his tongue, he pulls down the upper branches which have most leaves, and these he devours first. Having stripped the tree of its branches, he does not therefore abandon it; but, placing his snout as low in the trunk as he finds his horns will enter, he rips up the body of the tree, and reduces it to thin pieces, like so many laths; and when he has thus prepared it, he embraces as much of it as he can in his monstrous jaws, and twists it round with as much ease as an ox would do a root of celery, or any such pot-herb or garden-stuff.

"When pursued, and in fear, he possesses an astonishing degree of swiftness, considering his size, the apparent unwieldiness of his body, his great weight before, and the shortness of his legs. He is long, and has a kind of trot, which, after a few minutes, increases in a great proportion, and takes in a great distance; but this is to be understood with a degree of moderation. It is not true, that in a plain he beats the horse in swiftness. I have passed him with ease, and seen many worse mounted do the same; and though it is certainly true that a horse can very seldom come up with him, this is owing to his cunning, but not his swiftness. He makes constantly from wood to wood, and forces himself into the thickest part of them. The trees that are dry are broke down, like as with a cannon-shot, and fall behind

him,

him, and on his side, in all directions. Others that are more pliable, greener, or fuller of sap, are bent back by his weight, and the velocity of his motions; and, after he has passed, restoring themselves like a green branch to their natural position, they sweep the incautious pursuer and his horse from the ground, and dash them in pieces against the surrounding trees.

“The eyes of the rhinoceros are very small, and he seldom turns his head, and therefore sees nothing but what is before him. To this he owes his death, and never escapes, if there is so much plain as to enable the horse to get before him. His pride and fury then make him lay aside all thoughts of escaping, but by victory over his enemy. He stands for a moment at bay; then, at a start, runs straight forward at the horse, like the wild boar, whom, in his manner of action, he very much resembles. The horse easily avoids him, by turning short to a side; and this is the fatal instant: the naked man, with the sword, drops from behind the principal horseman, and, unseen by the rhinoceros, who is seeking his enemy, the horse, he gives him a stroke across the tendon of the heel, which renders him incapable of further flight or resistance.

“In speaking of the great quantity of food necessary to support this enormous mass, we must likewise consider the vast quantity of water which he needs. No country but that of the Shangalla, which he possesses, deluged with six months’ rain, and full of large and deep basins, made in the living rock, and shaded by dark woods from evaporation, or watered by large and deep rivers, which never fall low or to a state of dryness, can supply the vast draughts of this monstrous creature. But it is not for drinking alone that he frequents wet and marshy places: large, fierce, and strong as he is, he must submit to prepare himself against the weakest of all adversaries. The great consumption he constantly makes of food and water necessarily confine him to certain limited spaces; for it is not every place that can maintain him. He cannot emigrate, or seek his defence among the sands of Atbara.”

The rhinoceros with two horns was the species described by Martial, under the name of *rhinoceros cornu gemino*, who relates its combat with the bear.

“Namque gravem gemino cornu sic extulit ursum,  
Jactat ut impositas taurus in astra pilas.”

Spect. Epig. 22.

The Romans, who procured their rhinoceroses from Africa, represent them with double horns. That figured in the Prench pavement, and that in a coin of Domitian, have two horns; that which Pausanias describes (ix. 9.) under the name of Ethiopian bull, had one horn in the nose, and another lesser higher up; and Cosmas Ægyptius (tom. ii. 334.), who travelled into Æthiopia, in the reign of Justinian, also attributes to it the same number. Augustus introduced a rhinoceros (probably of this kind) into the shows, on occasion of his triumph over Cleopatra. Dion Cassius, lib. ii. Phil. Transf. abr. vol. ix. ubi supra. Id. vol. lvi. p. 32, &c.

M. Geoffroy of France thinks there are, or at least have been, no less than five different species of the rhinoceros; viz. 1. The rhinoceros africanus, cornu gemino of Camper, who has given a figure of the skull in the Petersburg Transactions for 1777. 2. The species found fossil in Siberia, which M. Geoffroy contends is different from the common two-horned rhinoceros, though of that division of the genus. 3. That of which the skull is figured by Camper, and described by him in a letter to Dr. Pallas, in the Petersburg Transactions. This is a single-horned species, and has been often confounded with the common rhinoceros.

4. The common single-horned Asiatic rhinoceros. And 5. The Sumatran rhinoceros, described by Mr. Bell in the Phil. Transf. of the Royal Society of London.

RHINOCEROS *avis*, in *Ornithology*, the rhinoceros-bird, a name given by authors to a species of Indian raven, called by others *corvus Indicus cornutus*; the beak of which is frequently brought over into Europe. This, in the Linnæan system, is a species of *Buceros*; which see.

It is a very ugly bird, and of a very rank smell. It much exceeds the European raven in bigness, and its head and neck are very thick. Its eyes are very large, and its beak of a very remarkable figure, having a large and thick horn-like protuberance on its upper part. The whole beak is bent like a bow, not hooked at the end like the beaks of the hawk, &c. It is of a yellowish-white below, and on the upper part towards the head is of a fine gay red, and the rest of a yellowish-white; the upper chap is ferrated. The horn grows out from the head with this, and runs along it, and ends up at its extremity; its upper and under part are red, its middle yellow. The bird feeds on carrion.

RHINOCEROS, in the *History of Insects*, a species of beetle, so called, because it has a kind of horn upon its head.

RHINOCOLURA, or RHINOCORURA, in *Ancient Geography*, a town of Syria, 22 miles from Raphia, and which formed a kind of boundary between Syria and Egypt. Strabo attributes it to Phœnicia; and Pliny calls the sea, on a strait of which this place is situated, the “Sea of Phœnicia.” Diodorus Siculus says, that this town, situated on the confines of Egypt and Syria, near the sea, was destitute of all the conveniences of life; that its water was bitter and noxious, and that it was surrounded with salt marshes. It was in the vicinity of this place that the Israelites were nourished with quails.

RHINOMACER, in *Entomology*, a genus of insects of the order Coleoptera. The generic character is, antennæ fetaceous, seated on the snout; it has four feelers, growing thicker towards the end; the last joint is truncate. There are three species, none of which are found in this country.

#### Species.

CURCULOIDES. This is grey and downy; the antennæ and legs are black. It inhabits Italy. It resembles a curculio. The antennæ are fetaceous and black, and as long as the thorax; the last joint is sharp; the snout is flat, and impressed in the middle.

ATELABOIDES. This is piceous-downy; the antennæ and legs are testaceous. It is found in divers parts of Sweden. The snout is elevated and projected; the body is cinereous.

CERULEUS. This species is of a blueish colour, and it is subvillous; the base of the antennæ and legs are yellow. It inhabits Calabria, and has been thought to be a species of the *Atelabus*; which see.

RHINOPTES, a word used by the ancients to express a person, who, from an ulcer in the great carthus of the eye, laying open the passages to the nose, can see through his nostril.

RHINOW, in *Geography*, a town of the Middle Mark of Brandenburg, on the Rhine; 20 miles N. of Brandenburg.

RHINSBERG. See REINSBERG.

RHINSBERGERS, in *Ecclesiastical History*. See COLLEGIANS.

RHIPÆI MONTES, in *Ancient Geography*. See RIPHÆAN Mountains.

RHIPSALIS, in *Botany*, Gærtn. t. 28. (See CACTUS, sp. 25.) It is curious to observe how the representation of the fructification of this plant, in Miller’s Illustration of the Linnæan system, is made to answer to the generic character of *Cassipha*, for which it had been erroneously taken.

RHIPTASMOS, a word used by the ancients to express

prefs a restlessness and frequent tossing about, a very common symptom in fevers.

RHISOPHAGI, in *Ancient Geography*, a people of Ethiopia, in the vicinity of the isle of Meroe, upon the banks of the rivers Astaboras and Altapas, according to Diodorus Siculus.

RHISPIA, a town of the Higher Pannonia, at a distance from the Danube, and situated between Savaria and Vincendria. Ptolemy.

RHISUS, a town of Greece, on the coast of Thessaly, according to Strabo and Steph. Byz. Pliny mentions a town of this name in Magnesia.

RHITHYMNA, a town situated on the northern coast of the isle of Crete. Ptolemy.

RHITIA, a town of Africa, in Mauritania Cæsariensis; placed by Ptolemy in the interior of the country between Arina and Victoria.

RHITTIUM, a town of Lower Pannonia, upon the banks of the Danube, between Acumincum Legio and Taururum, according to Ptolemy.

RHIUM, a promontory on the N.E. part of Achaia: it formed with Anti-Rhium, another promontory opposite to it, and more northerly, the strait by which the Ionian sea communicated with the gulf of Corinth.—Also, a town of the Peloponnesus, in Mellenia, upon the gulf of Thuriates, opposite to the promontory Tanarus, according to Strabo.—Also, a promontory on the E. side of the island of Corfa, between mount Rhætius and the town Urcipium. Ptolemy.

RHIUSIAVA, a town of Germany, on the banks of the Danube, between Aræ Flaviæ and Alcimænis. Ptolemy.

RHIW-ABON, or RUABON, in *Geography*, a market-town in the cwmwd of Maelor Gymraeg, cantref of Uwck-Nant, (now called the hundred of Bromfield,) county of Denbigh, North Wales, is situated on rising ground, at the distance of four miles S.S.W. from the town of Wrexham. The market-day here is Monday, weekly; besides which, there are fairs on the last Friday in February, the 22d of May, and the 20th of November. The petty sessions for the Ruabon division of the hundred are held in this town. The church is an ancient structure, but is in good repair, and contains several monumental erections. One, to the memory of the first sir Watkin Williams Wynne, displays a figure of the deceased in a loose robe. On one side is a figure of his son, and on the other that of his daughter, both in kneeling postures. This monument was erected by Rybbrack. Near it stand those of the late sir Watkin Williams Wynne, bart., and his lady; both of them the workmanship of Nollekens, and worthy of his chaste and classic chisell. The latter exhibits lady Wynne in the character of Hope, standing, and reclining her arm on an urn; the whole being placed upon a pedestal, made in the shape of a Roman altar. The other principal monuments commemorate Henry Wynne, esq., tenth son of sir John Wynne of Gwidir, who died in 1671; sir John Wynne of Wynllay, and his wife Jane; and another sir John Wynne, son of the above, with his wife, the heirs of Watllay. In a chapel, on the south side of the communion table, is likewise an altar tomb, supporting the recumbent figures of a man in armour, and a female habited in a mantle. From an inscription round the edge of the entablature, it appears that these represent John ap Ehs Eyton, esq., who died in 1526, and Elizabeth Caffley, his wife, who died in 1524.

Rhiw-Abon is noted as the birth-place of Dr. David Powell, who translated into English the History of Wales, written by Caradoc of Llancarfan, with the Continuation by Humphrey Llwyd; and who likewise first edited the works of Giraldus Cambrensis, and published a treatise, en-

titled “De Britannica Historia recte intelligenda.” He died in 1590. This parish is very extensive, and contains five townships. The town consists, according to the population returns of 1811, of 263 houses, and 1137 inhabitants. The parish abounds with collieries, the produce of which is conveyed to different parts of the country, by means of the Ellesmere canal, which passes near the town, and forms a junction with the canals that penetrate Wales on the one side, and communicate with the Grand Trunk Navigation on the other. Adjoining Rhiw-Abon is Wynnllay-hall, the seat of sir Watkin Williams Wynne, bart. The house is large, but, owing to the heterogeneous and patched character of its architecture, it possesses little elegance of external appearance. The apartments in the interior, however, are grand and spacious, and contain several good portraits of the Wynnes, the Williamses, and the Seymours, painted by Vandyke, sir Godfrey Kneller, and other eminent artists. Close to the house is a building, originally fitted up as a theatre, but now appropriated for an annual agricultural meeting, auxiliary to the society at Wrexham. A show of cattle takes place on the occasion of each meeting, at which premiums are adjudged for the best specimen of every species of stock, and also for other husbandry improvements. This estate was anciently the residence of Madoc ap Gryffydd Maelor, lord of Bromfield, and founder of Valle-Crucis abbey. From the circumstance of the ancient rampire, called Watt’s Dyke, running through the park, it was long denominated Watllay-park, in allusion thereto. It extends above eight miles in circumference, and is ornamented with plantations, a fine lake, and various buildings. Among the objects of the last mentioned kind is a column, 100 feet high, built of free stone, from a design by the late Mr. Wyatt. It was erected as a tribute of maternal affection, in memory of sir Watkin Williams Wynne, father to the present baronet. In another part of the grounds is a tower, or rotunda, intended to commemorate the heroes of the Cambrian legion, who fell in the cause of loyalty, under sir Watkin, during the late rebellion in Ireland. The spot on which this tower is situated commands an extensive view of mountains, woods, and the meanderings of the Dee. The valley, watered by that river here, displays the most picturesque and romantic scenery, whose beauties peculiarly excited the admiration of the celebrated lord Lyttelton. The turnpike-road from Rhiw-Abon to Oswestry, which crosses this valley, is formed for nearly two miles on the embankment of Offa’s Dyke. It is here ten feet high, and broad enough for two carriages to run abreast. Near this road is a remarkable tumulus, supposed to be the burying-place of some chieftain slain in a battle, fought in this neighbourhood, about the year 1161, between Owain Cyfelliog, prince of Powys, and the English, and terminated in favour of the ancient Britons. This victory gave rise to the beautiful poem, called “Hirlas Owain,” or the Drinking-Horn of Owain, composed by the prince himself; which, according to Mr. Pennant, ranks with the best Pindaric ode of the Grecian school. About three miles northward from Rhiw-Abon is Erdigg, or Erdig, the seat of Simon Yorke, esq. The house, which has been lately modernized, contains some valuable paintings; and the library is the depository of many curious Welsh MSS., including the Scabright collection. The grounds are laid out with much taste, but the efforts of art are too apparent. The continuation of Watt’s Dyke extends across these grounds, running along one side of a bank between the two vallies, by which the domain is bounded. Not far from hence are the fragments of a cemented wall, and various foundations of buildings, surrounded by a triple intrenchment of a pentagonal form.

These are supposed by some to be of Roman origin, but others conceive that they mark the site of a Saxon fort, constructed by the Mercians to defend their line of demarcation, as fixed by the great Offa. This last opinion is rendered the more probable, by the fact of there being some vestiges of a similar fort more to the northward, and on the same line. Philip Yorke, esq., ancestor to the present proprietor of Erddig, was author of "The History of the five royal Tribes of Wales;" a work abounding with much information, that it is greatly to be lamented that he did not favour the world with his intended *Stemmata*, or Fifteen Tribes.

The district in the vicinity of Rhiw-Abon, particularly towards Wrexham, abounds with valuable mines. The iron ore, found in the adjacent mountains, is exceedingly rich, and affords excellent iron. The principal works carried on are those of Brymba and Berham. The latter, which are situated at Pont-y-Penca, consist of forges, slitting, rolling, and stamping mills, &c. with an extensive cannon foundry, inferior only to that on the banks of the Carron, in North Britain. Besides cannon, these works produce wheels, cogs, bars, pipes, cylinders, rollers, columns, pistons, &c.; also furnace boilers, steam caissons, and various other articles which were formerly made of copper. Carlisle's *Topographical Dictionary of Wales*, 4to. 1813. A Tour round North Wales, by the Rev. W. Bingley, B.A., F.L.S., 8vo. 2 vols. 1800.

RHIZAGRA, in *Surgery*, an instrument for extracting the stumps of the teeth.

RHIZANA, in *Ancient Geography*, a town placed by Ptolemy in the interior of Dalmatia.—Also, a town of Asia, in Gedrosia, upon the sea-coast near Coimba. Ptol.—Also, a town placed by Ptolemy in Arachosia, between Alexandria and Arbaca.

RHIZINIUM, or RHISINUM, or *Rhison*, a town of Dalmatia, on a gulf to which it gave the name of Rhisonicus Sinus. Ptol.

RHIZIUM, RHIZÉ, a town of Asia, in the Colchide, on the coast of the Euxine sea, and W. of the mouth of the small river "Rhizius."

RHIZOBOLUS, in *Botany*, a name of Gærtner's, from  $\rho\acute{\iota}\zeta\alpha$ , a root, and  $\beta\omicron\lambda\lambda\alpha$ , to *ibrozw*, or *cast*, because the plant is remarkable for throwing out a number of roots.—Schreb. 369. Mart. Mill. Dict. v. 4. Gærtn. t. 98. (Caryocar; Linn. Mant. 154. Willd. Sp. Pl. v. 2. 1243. Pekea; Aublet. Guian. v. 1. 594. Juss. 249. Lamarck Illustr. t. 486.)—Class and order, *Polyandria Tetragynia*. Nat. Ord. *Sapindi*, Juss.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, fleshy, cloven half way down into five, roundish, concave segments. *Cor.* Petals five, ovate, rounded, concave, fleshy, inserted below the segments of the calyx, and much larger. *Stam.* Filaments very numerous, thread-shaped, longer than the corolla, inserted into the receptacle; anthers roundish. *Pist.* Germen superior, square, in the bottom of the calyx; styles four, thread-shaped, longer than the corolla; stigmas obtuse. *Peric.* Drupus four, kidney-shaped, compressed, inserted by their wedge-shaped inner edge into the conical receptacle, of one cell, with a fleshy covering, and a soft pulp like butter. *Seed.* Nuts solitary, kidney-shaped; kernels solitary, kidney-shaped.

Eff. Ch. Calyx five-cleft half way down. Petals five. Germen four-sided, superior. Nuts four, single-celled and single-seeded.

1. *R. butyrosus*. Lesser Suwarrow Nut. (Caryocar butyrosifolium; Willd. n. 1. Pekea butyrofa; Aubl. Guian. t. 238.)—Fruit smooth. Leaves digitate, smooth on both sides.—Native of woods in Guiana, and cultivated at Ca-

enne; where it flowers in June and July, and bears fruit in September. This lofty *tree* rises to the height of eighty feet, or more, and is much branched at the summit; the inner branches erect; the outer horizontal or declining. *Trunk* three feet in diameter, with a grey *bark*, and reddish, compact *wood*. *Leaves* opposite, digitate; leaflets entire, oval, pointed. *Flowers* white, in large bunches, at the extremities of the branches. *Fruit* yellowish.

2. *R. tuberculifolius*. Large, or Common, Suwarrow Nut. (Caryocar tomentosum; Willd. n. 2. C. nuciferum; Linn. Mant. 247. Pekea tuberculosa; Aubl. Guian. t. 239.)—Fruit tubercled. Leaves digitate, downy beneath.—Native of Guiana, producing fruit in July. This *tree* differs from the preceding in having thicker *leaves* which are downy beneath, and ash-coloured. *Fruit* larger and tubercled, the pulp dry, not buttery. The *nut* is sweet and palatable, containing a rich oil. Not unfrequently in our fruiterers' shops, and known by the name of Suwarrow Nut. It is figured in Cluf. Exot. 27. f. 1, by the name of *Amygdala guianensis*.

RHIZOMA, an appellation bestowed, by several late authors, on the tuberous *caudex*, or body, of some roots; as that of *Iris Germanica*, and many other of the natural order of *Ensatæ* of Linnæus and Gawler. See *ROOT*.

RHIZOMORPHA, so called from its resemblance to the branching fibrous roots of various plants, is a genus of fungi, established by Persoon, in his *Synopsis*, 704. One of its species, *R. subcorticalis*, figured by Micheli, Nov. Gen. t. 66. f. 3, is called by that author, p. 125, *Agaricum nigrum reticulatum compressum, e mortuis arboribus inter corticem et lignum, interdum in ipso ligno innascens, ac latè se distendens*. Ray, Vaillant, and others, have likewise considered this substance as a fungus. Persoon's generic character is

"Creeping, rigid, smooth, with a villous pith."

He enumerates two species besides the above; *subterranea*, found among wet timber-work, in mines; and *setiformis*, found among dead leaves in woods. This last is figured in Dill. Musc. t. 13. f. 11, b. They are all, to us, very obscure, and perhaps imperfect productions.

RHIZOPHORA, a Linnæan genus, whose name is derived from  $\rho\acute{\iota}\zeta\alpha$ , a root, and  $\varphi\epsilon\acute{\rho}\omega$ , to bear, or carry; the seed germinating before it falls from the branches, and sending down a remarkably long cylindrical root into the earth.—Linn. Gen. 236. Schreb. 317. Willd. Sp. Pl. v. 2. 843. Mart. Mill. Dict. v. 4. Juss. 213. Lamarck Dict. v. 6. 187. Illustr. t. 396. Gærtn. t. 45. Loureir. Cochinch. 296. (Mangles; Plum. Nov. Gen. t. 15. Bruguiera; Lamarck Illustr. t. 397.)—Class and order, *Dodecandria Monogynia*. Nat. Ord. *Holeraceæ*, Linn. *Carpifolia*, Juss.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, spreading, cloven into four, or more, oblong, acuminate, permanent segments. *Cor.* Petals four or more, oblong, somewhat shorter than the calyx. *Stam.* Filaments scarcely any, alternately shorter; anthers from four to twelve, small, pointed. *Pist.* Germen superior, roundish; style awl-shaped, cloven half way down, grooved at each side; stigmas acute. *Peric.* fleshy, nearly ovate, including only the base of the seed. *Seed* solitary, oblong-club-shaped, pointed, fleshy at the base.

Obf. The number in the parts of the flower varies.

Eff. Ch. Calyx four or five-cleft. Corolla of four or five petals. Seed solitary, very long, fleshy at the base.

1. *R. conjugata*. Linn. Sp. Pl. 634. Fl. Zeylan. 81.—Leaves ovate-oblong, rather obtuse, entire. Calyx sessile. Fruit cylindrical, awl-shaped.—Native of India. All that is known of this species may be gathered from the *Flora Zeylanica*, where it is described as a *tree* whose *leaves* are flaked, smooth. *Calyxes* twin. *Fruit* very long, pendent.

2. *R. gymnorhiza*. Linn. Sp. Pl. 634. (Mangium celum; Rumph. Amboin. v. 3. 102. t. 68.)—Leaves ovato-lanceolate, entire. Root lying upon the ground.—Found in many parts of the East Indies, and in the islands of the South seas.—A middling-sized tree with a lofty, erect trunk, covered with a thick brown-red bark. Leaves on stalks, smooth, feathered, sometimes heaped together at the top. Flowers solitary, scattered, red, having usually from ten to thirteen petals, and twice as many stamens.

The bark of this tree is useful in dyeing a rufous or chefnut colour, which may easily be changed into a fine permanent black, as Loureiro informs us.

3. *R. Candel*. Linn. Sp. Pl. 634. (Tsjerou-Candel; Rheede Hort. Malab. v. 6. 63. t. 35.)—Leaves obtuse. Flower-stalks in forked pairs, longer than the leaf. Fruit awl-shaped. Native of the East Indies in shallow salt water. A tree about seven feet high. Leaves opposite, on short stalks, rather long, with round edges. Flowers composed of five or six thick, reflexed, white, slightly fragrant petals. Fruit very like that of the following species.

4. *R. Mangle*. Mangrove-tree. Linn. Sp. Pl. 684. Jacq. Amer. 141. t. 89. Browne Jam. 211.—Leaves pointed. Fruit slender-club-shaped. Found in moist situations, both in the East and West Indies. A tree about fifty feet high, with white wood, and a rusty-coloured bark. Leaves ovate, ribbed, entire, shining, coriaceous, dotted beneath. Stalks axillary, solitary, two or three-flowered, slightly triangular. Flowers white, having mostly eight petals.

Jacquin and Browne each give an elaborate and curious description of the fruit of this tree and the mode in which the seed germinates. From its growing usually near the sea, the lower branches frequently become a support to the American oyster, and this circumstance doubtless gave rise to an ancient fabulous opinion, that shell-fish sometimes grew on trees, like fruit.

5. *R. cylindrica*. Linn. Sp. Pl. 635. (Cari-Candel; Rheede Hort. Malab. v. 6. 59. t. 33.)—Fruit cylindrical, obtuse.—Native of salt marshes in Malabar. This species is closely allied to *gymnorhiza*, of which indeed Gærtner considers it to be a variety. It is rather taller, and not so much branched. Leaves much smaller, and on shorter stalks. Fruit green when young, but afterwards reddish-blue.

*R. corniculata*. See ÆGICERAS.

*R. castolaris*. See SONNERATIA.

We dare not venture to adopt *R. sexangula* of Loureiro, without further information than is furnished by that author respecting it.

RHIZUS, in *Ancient Geography*, a part of Cappadocia, near Trebizond, between the town of Pitiusa and the promontory of Athenæ. Ptolemy.

RHO, in *Geography*, a town of Italy, in the department of the Olona; eight miles W. of Milan.

RHOARA, in *Ancient Geography*, a town of Asia, in Parthia, between Casipraea and Semina. Ptolemy.

RHOAS, a river of the Colchide, according to Pliny.

RHOBASCI, a people of Scythia, on this side of the Imaus, placed by Ptolemy near the most easterly sources of the river Rha.

RHOBODUNUM, a town of Germany, upon the banks of the Danube, between Phelicia and Andupedum. Ptolemy.

RHOBODIUM, a promontory placed by Ptolemy in the northern part of Hibernia.

RHOBONDA, a town of Africa, in Mauritania Cæsariensis, between Tupufuptus and Aufum. Ptolemy.

RHOCAS, the watery eye. See EPIPIORA.

RHODA, or RHODE, *Rofas*, in *Ancient Geography*, a town of Hispania Anterior, belonging to the Indigetes, and

N. of a small gulf. It is said to have been built by the Rhodians on the banks of a small river which flowed from the Pyrenées, and called by Pomponius Mela "Thicis." But Cellarius conjectures that it was founded by the inhabitants of Emporia, who came thither from the town of Rhodes, in the island of that name.—Also, a town of Gallia Narbonensis, at the mouth and on the banks of the Rhone, according to Pliny; who adds, that it was built by the Rhodians. St. Jerome intimates that the Rhone took its name from this town.

RHODANNUS, or RODANNUS, a small river which had its source in the palatinate of Pomerania, and discharged itself into the Vistula at Dantzick.

RHODANUS FLUVIUS. See RHONE.

RHODE, a river of the European Sarmatia, in the vicinity of the Axiaes. Pliny.

RHODE Island, in *Geography*, one of the United States of America, situated between  $41^{\circ} 17'$  and  $42^{\circ}$  N. lat. and between  $71^{\circ} 6'$  and  $71^{\circ} 52'$  W. long. Its north line is 29 miles long and its west line 49. The coast west of the bay measures 22 miles, the mouth of the bay 16, and the coast east of the bay 5, in all 43; while the greatest width measured on a parallel is 37 miles. Rhode island contains about 1580 square miles; of which about 190 are water, and about 90 are included in the islands. It is bounded N. and E. by the Massachusetts, S. by the Atlantic, and W. by Connecticut. It is divided, according to the following statement, into five counties and thirty-one townships.

Counties.	No. of Towns.	Population.			Chief Towns.
		1790.	1800.	1810.	
Providence	- 10	24,391	25,854	30,769	Providence.
Newport	- 7	14,300	14,845	16,294	Newport.
Washington	- 7	18,075	16,135	14,968	S. Kingston.
Kent	- 4	8,848	8,487	9,834	Warwick.
Bristol	- 3	3,211	3,801	5,072	Brillol.
Totals	- 31	68,825	69,122	76,937	

This state sends two representatives to congress. The tribe of Indians who inhabited Rhode island at the time of its settlement, was the Narragansetts, who were a brave and powerful people. The first settlement in this state was made by Roger Williams, and a party of malecontents from Massachusetts, in 1635; and in 1643 a charter was obtained for the whole colony by sir Henry Vane. The charter, on which the present constitution is founded, was obtained of Charles II. in 1663. In May 1789, Rhode island adopted the federal constitution. The inhabitants of this state are chiefly of English descent. Agreeably to the charter just mentioned, the legislature is composed of a council of 12, including the governor and deputy governor, all chosen annually, and a house of representatives, consisting of deputies from the several towns, chosen twice a-year. There is one supreme court, which sits twice a-year in each county, and an inferior court of common pleas and general sessions of the peace for each county, sitting also twice a-year. The militia of this state amount to between 7000 and 8000 men, organized and disciplined in a manner similar to the rest of the New England militia. The settlement of Rhode island is said to have originated in a religious dispute; and some of its first settlers were exiles from the Massachusetts, on account of their religious opinions. The prejudice and animosity thus excited were never thoroughly removed; but they were long cherished by the descendants of the first occupiers; and even to this day, there has never been a congregational minister settled on the west side of the bay,

bay, except in Providence. The mass of the people, it is said, on the west side of the bay, has generally been ignorant, irreligious, and loose in their morals. The tone of religious sentiment and of morals, in Providence, Newport, and Bristol, and other towns adjoining these on the east of the bay, has been much raised by the emigrants from Massachusetts and Connecticut, and the establishment of religious institutions. The traveller sees few of the improvements in agriculture, roads, manufactures, or mode of living, which he finds in the neighbouring states; and meets with little of that civility for which other parts of New England are remarkable. The missionary labours, however, have not been without their good effects. With respect to the religious profession of this state, the Baptists are the most numerous; most of whom are Calvinistic; some are Arminians, and a few of them are seventh-day Baptists. A still smaller number consists of those who claim peculiar sanctity, and are denominated Separate Baptists. The other denominations are Congregationalists, who have eight ministers; Episcopians, who have four, one of whom is the bishop of the eastern diocese; Moravians, and Jews. In this state religion is not supported by law; but the clergy are maintained by the voluntary contributions of their people. The number of clergy, as they have no stated salary, enforced by law, is extremely small; but the state of religion and morals, in a great part of the state, is lamentably low. Literature has of late been encouraged. Brown university at Providence, deriving its present name from Nicholas Brown, esq., who gave the institution 5000 dollars, was founded in 1764 at Warren, and removed to Providence in 1770. (See COLLEGE.) Academies are established at Providence, Newport, Bristol, Warren, East-Greenwich, and South-Kingston. Schools are kept during the winter-months in most towns of the state, though not provided for by the laws; and upon the whole the state of society is improving. In this state there are 13 banks. The chief exports are flax-seed, lumber, horses, cattle, beef, pork, fish, poultry, onions, butter, cheese, barley, grain, spirits, and cotton and linen goods. More than 600 vessels enter and clear annually at the several ports. In 1804 the amount of exports was 1,735,671 dollars, and in 1810, 1,331,576 dollars. The imports consist of European and West India goods, and logwood from the bay of Honduras. The inhabitants, particularly those of Newport and Bristol, were, not long since, largely concerned in the slave trade, even in defiance of the laws of the state. A turnpike road passes from Providence, W.S.W., through Scituate and Coventry, meeting a similar road in Lisbon, Connecticut, which leads through Windham to Hartford; its length is about 25 miles. Another road strikes the Connecticut line S. of this, and passes through Norwich, New London, to New Haven and New York; this is the great southern road from Bolton to New York; but the roads in this state have been much neglected. This state is reckoned as healthy as any country in America. The winters in the maritime parts of the state are milder than in the inland country; and the summers are delightful: the extreme heats that occur in other parts of America, being allayed by cool and refreshing breezes from the sea. The rivers and bays swarm with various kinds of fish; and this state produces corn, rye, barley, oats, and in some parts wheat, sufficient for home consumption, and the various sorts of grasses, fruits, and culinary roots and plants in great abundance and perfection. Cyder is made for exportation. The north-western parts of the state are rocky and barren, and of course thinly inhabited. The tract of land lying between North and South Kingston on the east, and Connecticut on the west, called "Shannock" country, or "Purchase," is excellent grazing

land, and inhabited by a number of wealthy farmers, who rear some of the finest neat cattle in New England; they keep large dairies, and make butter and cheese of the best quality, and in large quantities for exportation. Iron ore is found in great plenty in several parts of the state; so that the most considerable manufactures of this state are those of iron; and also abundance of lime-stone, which furnishes lime for exportation. In this state are several mineral springs; and one in particular near Providence, to which many people resort for bathing, and for drinking the water.

RHODE Island, is an island from which the American state takes its name, near the coast of Massachusetts, about 40 miles S.W. from Bolton. It is about 15 miles from N. to S., and on an average  $3\frac{1}{2}$  miles wide, and is divided into three townships, viz. Newport, Portsmouth, and Middletown. This island is pleasant and salubrious, and is a noted place of resort for invalids from southern climates. Between 30,000 and 40,000 sheep are fed on the island, besides neat cattle and horses. N. lat.  $41^{\circ} 25'$ . W. long.  $71^{\circ} 20'$ .

RHODE River, the wellermost water of the N.W. branch of Cape Fear river, in North Carolina.

RHODEN, a town of Germany, in the county of Waldeck; 24 miles N.N.W. of Waldeck.

RHODES, *Island of*, in *Ancient and Modern Geography*, an island of Asia, situated in the Mediterranean, very near the coast of Caria or Natolia, and N.E. of the island of Crete, but much larger than this island. Pliny states its circuit at 125 miles; but Isidore makes it 103 miles. According to Sonnini, it is much longer than it is broad; its greatest length, in a direction from N. to S., being about 12 leagues, and breadth 6; and its circuit is commonly estimated at 44 leagues. Its form is nearly triangular, whence it obtained the name of "Trinaeria;" and it was also known formerly by the names of Ophiusa, Alteria, Aethrea, Cerymbia, Poessa, Atabyria, Marcia, Oloessa, Stadia, Telchinis, Pelagia, and Rhodus. The latter appellation has prevailed in later ages; and its etymology has been sought in the Greek Rhodon, signifying a rose, with which flower the island abounded. In confirmation of this etymology it has been alleged that several Rhodian coins are still extant, exhibiting, on one side, the sun, and on the reverse a rose. Diodorus Siculus deduces the origin of its name from Rhoda, the daughter of Apollo by Venus. Others, however, have preferred the etymology of Bochart, who, availing himself of one of its ancient names, viz. Ophiusa or Snake island, given to it on account of the numerous snakes with which it was infested, when it was first inhabited, says that the Phœnicians also called it Snake island, which, in their language, signified "Gesirat Rhod," the latter word meaning a snake, whence the Greeks afterwards formed the name of Rhodes, which the island has since preserved. Another name by which it was distinguished, in common with the island of Cyprus, was Macaria, or fortunate, referring to the nature of the climate and of the soil. But it is said to surpass Cyprus, if not with respect to the fertility of the land, at least by its milder and more agreeable temperature. In this island the heat is not excessive, so that long droughts do not burn the plants, dry up the waters, or cause the inhabitants to suffer. The fertility and productiveness of its soil gave occasion to the fable, embellished by the poets, of those golden showers which they pretended to have once fallen upon it. It formerly produced, in great plenty, all sorts of delicious fruits, and wines of so exquisite a flavour, that they were used by the Romans chiefly in their sacrifices, and thought to be, as Virgil informs us, (Georg. l. ii.) too good for mortals. Although the heat is not scorching, yet the air is so serene, that no day ever passes without sun-shine; whence the poets feigned Phœbus

to be in love with this island, which, as they say, was a mere marsh, altogether uninhabitable, till it was loved by Phœbus and raised out of the waters by his powerful influence. To this purpose Sonnini describes its temperate climate, pure air, and fine springs, which at all times supply the wants of its inhabitants, and render it agreeable; its vallies of a rich and fertile soil, covered by plentiful harvests, and clothed with rich pastures, shaded by trees bearing precious fruits, such as the olive, the orange, and the fig-tree, with flowers that embellish with their lustre, and perfume with their sweet emanations; sloping hills on which the vine is cultivated, or which present to numerous flocks a luxuriant and odoriferous herbage; mountains on which grow the most beautiful trees, whose verdure is perennial; all which would still render it one of the most delightful abodes in the world, did not the iron hand of the Turks efface a part of the colours of this smiling picture. A gloomy nakedness, says the same author, diffuses melancholy over places formerly adorned by the riches of nature and industry; and the men who are called thither by an agreeable and truly happy country, are driven back by the terror inspired by a horde of spoilers. Happiness no longer inhabits an island formerly "fortunate," and the golden shower, which the poets of antiquity caused to fall there, as an emblem of its riches and brilliant advantages, is converted into a storm of desolation.

In the time of Homer the island of Rhodes had three cities, *viz.* Lindus, now *Lindo*, Camirus or *Camiro*, and *Ialyfus*, the most ancient city in the whole island; to which in after ages was added a fourth, bearing the name of the island. (See each respectively.) These three cities were built, according to Diodorus, by Tlepolemus, the son of Hercules, before the Trojan war. But Strabo and Cicero inform us, that they were founded by the Heliades, or grandsons of Phœbus, Ialyfus, Camirus, and Lindus, who gave each of them his own name. Other writers say, that they were built by the Dorians not long after their migration; and hence Athenæus reckons them among the Dorian colonies. Herodotus says, they were founded by the daughters of Danaus, who landed in this island, after having put to death the sons of Ægyptus, their husbands. In the city of Lindus was a magnificent temple, built, according to Plutarch, in honour of the Lindian Minerva, a statue of which, together with the mother of Jupiter Dodonæus, both of exquisite workmanship, were found in the rubbish of the city, after it had been accidentally reduced to ashes, and removed to Constantinople. In this temple there were also several pictures by Parrhasius, Zeuxis, and other great masters. Lindus and Ialyfus were well fortified in the time of the Peloponnesian war, as we learn from Thucydides; but Camirus was without walls. The three cities now mentioned were, as Strabo informs us, three different republics, independent of each other, governed by their own laws, till the inhabitants abandoned them, and removed to the city of Rhodes.

This island was first peopled, according to Diodorus Siculus, by the Telchines from Crete; but dreading a deluge, they abandoned their habitations, and made way for the Heliades, or grand-children of Phœbus, who took possession of it, after Apollo had cleared it of the mud, with which it had been covered by the deluge. The Heliades, being infested with serpents, sent for Phorbas from Theffaly, upon the suggestion of the oracle at Delos, who brought with him a number of Theffalians, settled on the island, destroyed the serpents, and after his death was honoured as a demi-god. A colony of Cretans afterwards settled at Camirus, in this island, under the conduct of Althæmenes, son of Catreus, king of Crete; and by direction of the oracle,

he was honoured after his death as a hero or demi-god. Not long before the Trojan war, Tlepolemus, the son of Hercules, in compliance with the instruction of the oracle, which he consulted, left Argos, and settled in Rhodes. He here planted a colony, which he governed as king of the island with great equity. Diodorus says, these were the first inhabitants of Rhodes. After the Trojan war, the best part of the island was taken possession of by the Dorians, who expelled the ancient proprietors, and the Doric dialect was commonly used throughout the whole island.

The Rhodians applied themselves, at an early period, to trade and navigation, and for many ages were sovereigns of the sea: their laws being the standard by which all controversies relating to maritime affairs were decided. These laws and constitutions were so just, that they were afterwards incorporated into the Roman pandects, and followed in all the provinces of the Roman empire.

The government of Rhodes was originally monarchical; and several kings are said to have reigned there long before the Trojan war; but of these we have no account. Among the eminent writers of this island, we have an enumeration of the following, whose names we can only mention: *viz.* Aristophanes, Eudemus, Hieronymus, a Peripatetic philosopher, Leonidas, Pisander, Panetius, Apollonius Molon, Timocreon, Præciphanes, Anthæas, &c. The authors of the Universal History (ubi infra) have given a brief account of some of them, and referred for an ampler detail to Meursius's learned treatise on the island of Rhodes, printed at Amsterdam in 1675, and published with those on Crete and Cyprus by the same author.

In the time of the Trojan war, and after that epoch, the kings who reigned in this island were, Tlepolemus, Dorius, Damagetus, Diagoras, Evagoras, Cleobulus, Erasitides, Damagetus II., and Diagoras II. The last of these sovereigns proved conqueror in the Olympic, Isthmian, Nemean, and Argian games, and on that account is celebrated by Pindar. His three sons were also victors in the Olympic sports. Upon the death of Diagoras II. some extraordinary revolution must have happened; as another family had possession of the throne. After the death or expulsion of the last king, the republican government prevailed over the whole island; during which the Rhodians engaged in trade and navigation, became very powerful by sea, and planted several colonies in distant countries; *viz.* Rhodus in Spain, and Parthenope in the country of the Opici. At this time they were masters of the Balearic islands, then called the Gymnasian islands. During the Peloponnesian war the Rhodians first joined the Athenians, revolted from them to the Lacedæmonians, and afterwards joined the former. At this time the republic of Rhodes was rent into two factions, the people favouring the Athenians, and the nobles the Lacedæmonians; but the latter at last prevailed; democracy was abolished, and an aristocracy introduced in its room. Under this form of government the state enjoyed a profound tranquillity, until the third year of the 105th olympiad, which was the third year of the reign of Philip the son of Amyntas, when the Social war broke out, which, after it had lasted five years, was concluded by a treaty, very little to the honour of Athens. By this treaty, Rhodes, Chios, Cos, and Byzantium, were to enjoy full liberty, and be quite independent of Athens. The Rhodians, however, did not remain long unmolested; but they were oppressed by Mausolus, king of Caria, who had assisted them in throwing off the Athenian yoke. After suffering for some time, they equipped a fleet, invaded Caria, and regained their liberty. Artemisia, the queen of Mausolus, by an act of treachery, possessed herself of the city of Rhodes, and put to death the chief citizens

## RHODES.

citizens who had planned the Carian expedition. In this state of distress, the Rhodians resorted to the Athenians, and either by their assistance, or by exertions on their own part, after the death of Artemisia, were restored to their ancient liberty. From this time till the reign of Alexander the Great the Rhodians enjoyed undisturbed tranquillity; and as they delivered their cities and harbours to his custody, they were on that account highly favoured by that prince. Diodorus indeed tells us, that Alexander deposited his last will in the archives of the city of Rhodes, and shewed, on all occasions, a greater value for the Rhodians than for any other of the Greek nations. But they no sooner had heard of his death, than, taking up arms, they drove out the Macedonian garrisons, and once more became a free people. About this time Rhodes, the capital city, suffered very much from an inundation, accompanied by a tempest and hailstones of an extraordinary size, which demolished many houses, and killed a great number of the inhabitants. The Rhodians soon repaired the damage which they had sustained, by a renewed and very sedulous application to trade and navigation, the only sources of their wealth and power. Although they were in amity with the neighbouring princes, and were desirous of observing a strict neutrality, by which prudent caution they were become one of the most opulent states of Asia; yet their inclination, concurring with their interest, they secretly attached themselves to Ptolemy: the most advantageous branches of their commerce springing from Egypt. When Antigonos, who had engaged in a war with Ptolemy for the island of Cyprus, demanded succour of them, and they hesitated in declaring against their ancient friend and ally, his anger was excited, and he immediately ordered one of his admirals to sail with his fleet to Rhodes, and seize all the ships that sailed out of the harbour for Egypt. The Rhodians, finding their harbour blocked up by the fleet of Antigonos, equipped a great number of galleys, attacked the enemy, and obliged him, with the loss of many ships, to quit his station; Antigonos was incensed, and threatened to besiege their capital with his whole army. They remonstrated, but with little effect, and the only terms of accommodation they could obtain, were, that they should declare war against Ptolemy, that they should admit Antigonos's fleet into their harbour, and that 100 of their chief citizens should be surrendered as hostages for the performance of these articles. The Rhodians applied to their allies, and particularly to Ptolemy, for assistance; and after great preparations on both sides, Demetrius put himself at the head of a large body of troops, increased by pirates and mercenaries, who wished to plunder Rhodes of its riches, and having laid waste the country round the city, approached the city itself with his powerful forces, and fortified his camp with strong ramparts and a triple palisade. The Rhodians adopted every possible measure for a vigorous defence. After repeated assaults on the part of Demetrius, which were repulsed with great slaughter, he brought forward a newly invented machine, called "helepolis;" with a variety of other engines, and he employed in the management of them about 30,000 men. The besieged, in the mean while, raised a new wall, within that which the enemy intended to batter with the helepolis. The city was furiously assaulted on all sides, both by sea and land; and an honourable capitulation on the part of the Rhodians being refused by Demetrius, the attack was renewed, and a breach made in the wall; but the besieged fought in the breach with such intrepidity, that the enemy, after several unsuccessful attempts, were forced to abandon the enterprise and retire. A seasonable supply of provisions arriving safe at Rhodes, the besieged gained new courage, and determined to set fire to the enemy's engines.

In the execution of this project a great number of Demetrius's troops fell victims, and the conflagration was so great, that Demetrius thought it most prudent to move off his machines, lest they should be utterly destroyed. Whilst the Rhodians were thus, with equal valour and perseverance, defending themselves and annoying the enemy, an embassy arrived at the camp of Demetrius from Athens, and the other cities of Greece, soliciting him to make peace with the Rhodians. A cessation of arms was agreed upon, and terms were offered by Demetrius, which were rejected by the Rhodians. The assault was renewed, and a breach having been made, it was entered by a detachment of Demetrius's men; which occasioned great confusion in the city: but the Rhodians fought like men in the utmost despair, and animated by their leaders, who encouraged one another, they proposed a last effort for the defence of their city and country, which was that of breaking into the very centre of the enemy's battalion, in the execution of which measure they killed both their commanders. After their death, the rest were easily thrown into disorder, and all to a man were either killed, or taken prisoners. The Rhodians also, on this occasion, lost many of their bravest commanders. At length the helepolis was rendered useless, by the stratagem of a Rhodian engineer, and this misfortune, it is said, induced Demetrius to conclude a peace. Thus the siege, after it had continued a whole year, was raised (B.C. 303); and the Rhodians amply rewarded all those who had distinguished themselves in the defence of their country. One instance of laudable conduct on the part of Demetrius during the siege deserves to be recorded. At this time Protogenes, a celebrated painter, who was a native of Cannus, a city of Caria, resided at Rhodes. His house was in the suburbs; and he could not be prevailed upon to quit it. The prince, surprised at this resolution, asked him why he did not, like the other inhabitants, secure himself within the walls? Protogenes replied, that he was under no apprehension, since he was sensible that Demetrius had declared war against the Rhodians, and not against the arts. The prince was so pleased, that he took the painter under his protection, and placed a guard round his house, to preserve him from the insults of the soldiery. The chef-d'œuvre of this Protogenes was the picture of Ialysus, supposed by the Rhodians to have founded their city. The Rhodians having concluded a peace upon advantageous and honourable terms, devoted themselves again to trade and navigation; by which they not only became masters of the sea, but the most opulent and flourishing state of all Greece. Their next war was with the Byzantines; and about the time of its termination the famous Colossus of Rhodes was overturned by an earthquake, which did other considerable damage. In the year B.C. 203, the Rhodians joined Attalus, king of Pergamus, against Philip, king of Macedon; and a triple alliance was formed between the Romans, Attalus, and the Rhodians. In process of time, the fidelity of the attachment of the Rhodians to the Romans, of which they had once and again exhibited unequivocal evidence, was suspected; and this suspicion was confirmed when they engaged with Perseus, the son of Philip, to stand neuter. The Roman senate was incensed, and the Rhodians sent messengers to appease their wrath, but their efforts were unavailing. At length, however, in the year B.C. 166, they were admitted to an alliance with Rome and favoured by the senate. From this period, to the breaking out of the Mithridatic war, the Rhodians enjoyed their liberties, while all the other states and colonies of Greece were brought under the Roman yoke, and became provinces of that republic. In the civil war between Cæsar and Pompey, they sided with the latter with a numerous fleet; but after the death of Pompey

they sided with Cæsar, which drew upon them the displeasure of C. Cassius, who advanced to their island with a powerful fleet, and demanded the surrender of their fleet, with which demand they refused to comply. The consequence was a sea-engagement, in which the Rhodians were defeated; and it has been observed, that this was the first time in which they were fairly overcome in a sea-fight. Cassius proceeded to take possession of Rhodes and to plunder it. He also ordered fifty of the chief citizens to be put to death, and others were proscribed. He stripped them of all their money, and even the temples of all their valuable furniture, vessels and statues. He announced, by a public cryer, that any person who should discover any hidden treasures should receive a tenth part by way of recompence; and the result was, that he thus extorted from private persons above 8000 talents. He then fined the city in 500 more, and leaving L. Varus, with a strong garrison to exact the fine, without any abatement, he returned to the continent.

After the death of Cassius, Marc Antony restored the Rhodians to their ancient rights and privileges, bestowing upon them the islands of Andros, Naxos, Tenos, and the city of Myndus. But these the Rhodians so oppressed and loaded with taxes, that Antony, though a great friend to the Rhodian republic, was obliged to divest her of the sovereignty over those places, which he had, a little before, so liberally bestowed upon her. From this time to the reign of the emperor Claudius, we find no mention made of the Rhodians. That prince deprived them of their liberty for having crucified some Roman citizens. However, he soon restored them to their former condition, as we read in Suetonius and Tacitus. The latter adds, that they had been as often deprived of, as restored to, their liberty, by way of punishment or reward for their different behaviour, as they had obliged the Romans with their assistance in foreign wars, or provoked them with their seditions at home. Pliny, who wrote in the beginning of Vespasian's reign, styles Rhodes a beautiful and free town. But this liberty they did not long enjoy, the island being soon after reduced, by the same Vespasian, to a Roman province, and obliged to pay a yearly tribute to their new masters. This province was called the province of the islands. The Roman prætor, who governed it, resided at Rhodes, as the chief city under his jurisdiction; and Rome, notwithstanding the eminent services rendered her by this republic; thenceforth treated the Rhodians not as allies but vassals.

Under Constantine this island remained part of the Eastern empire; but the pusillanimity and vices of the princes who succeeded, shook it to its foundation. In the twelfth year of the reign of Constant, Moawiah, Othman's lieutenant, made himself master of Rhodes. At length the Greek emperors expelled the Mahometans, and kept possession till the time of Baldwin, who, having made himself sovereign of Constantinople, sent a prætor to Rhodes. Some time after it was conquered by Ducas. Then the brave warriors, known by the name of the knights of St. John, attacked, and, after a bloody battle, took it; in which heroism triumphed over numbers and valour. Mahomet II. tarnished the lustre of his laurels, by besieging this place, defended by a small band of heroes. In the year 1523, Soliman saw a numerous army perishing under its walls; and if this redoubtable conqueror of Hungary and Persia did at length subdue Rhodes, attacked on all sides by the forces of the Turks, the greater was the shame of the Christian princes, who did not send a single vessel to the aid of its intrepid defenders. Destroyed, rather than vanquished, they were almost buried under the ruin of their forts. Seliman could not enter the town without wading through the blood of his soldiers; and in it he found nothing but heaps of

ruins, defended by a small company of knights, covered with wounds, who afterwards removed to Malta. (See MALTA). The governor-general of this island is a pacha, who has absolute power. The Greeks and Jews have a chief, named the Moutevali, who is their intendand-general, and has the regulation of the tax, called carach,—a capitation tax imposed by the grand seignior on all his subjects who are not Mahometans, but is paid only by the men.

The soil of the island is dry and sandy, but watered by its numerous springs. It is very fertile; corn thrives well; and its yellow and heavy grain affords flour as white as snow, which makes excellent bread. It needs only cultivation to raise an ample supply, not only for its own consumption, but for a large exportation. The number of families in the whole island is estimated at 4700 Turks, 2500 Greeks, and 100 Jews, in all 7300, or about 36,000 inhabitants. N. lat. 36° 26'. E. long. 27° 32'.

RHODES, the capital city of the island above described, as well as the chief seat of its government, is situated to the N.E. of the island, at the foot of a hill of gentle ascent, and in an agreeable plain, environed at some distance with several hills full of springs, and covered with all kinds of fruit-trees. This stately city was built by the same architect whom the Athenians had employed in building the Piræus, or part of Athens; viz. Hippodamus, a native of Miletus, and esteemed one of the best architects Greece ever produced. It was built, according to Strabo and Aristides, in the form of an amphitheatre, surrounded with walls like those of Munichia, embellished with most stately buildings, straight and broad streets, pleasant avenues, fine groves, large squares, &c. Dio Chrysofostom says, that most of the Pagan deities had temples in this city; among which that of the Sun, called by the Dorians Halcium, was one of the most noble structures of antiquity. Strabo mentions the temple of Bacchus, enriched with a great number of pictures by Protogenes, Hefychius, Appian, and Suetonius, speak of the temples of Iûs, of Oceridian, and Diana, as master-pieces of art. Each of these temples contained immense treasures, the offerings of votaries from all parts of Greece, Asia, and Italy. In the Dionysium, or temple of Bacchus, was a statue of Pluto of massy gold, and an incredible number of other statues and pictures. Pliny informs us, that, in his time, there were in the city of Rhodes above 3000 statues, most of them executed with great taste; and Aristides says, that there were more valuable statues and pictures in this single city than in all the other cities of Greece. The pictures of Menander, king of Caria, and of Anæus, the son of Neptune, by Apelles, and those of Perseus, Hercules, and Meleager, by Xeuxis, are highly extolled by Pliny, and other ancient writers. That of Meleager was there scorched by lightning, as Pliny tells us, but that accident did not in the least deaden the lustre and brightness of its colour.

In the Roman times this city was famous for the study of all sciences, and resorted to by such of the Romans as were desirous of improving themselves in literature; some of the ancients representing it as equal to Athens itself. It had a very convenient harbour, at the entrance of which were two rocks; and on these rocks, though 50 feet asunder, the famous colossus is supposed to have stood. See COLLOSSUS.

The city of Rhodes is still a place of considerable note; being pleasantly situated on the side of a hill, three miles in compass, and fortified with a treble wall; but its ramparts partake of the same neglect and decay of every thing that is in the possession of the Turks. The streets are wide, straight, and well paved; and the houses built after the Italian taste. The chief haven is now very different from what it is said to have been in its ancient state. It is no longer;

longer that basin, whose deep waters afforded a commodious shelter to ships of every size; nor are the quays enlivened by the activity of a flourishing trade. It is now little frequented except by Greek boats, and by a few merchant vessels which put in there; it is half choked up, and ships of war are obliged to cast anchor without, where they are but indifferently protected from the winds and waves by some points of land and some shoals. The entrance of the harbour is defended, on the one side, by a square tower, constructed by a grand master of the order; inscriptions and other marks recall to mind the period of its foundation. The Turks still call it St. John's tower, although the Greeks have changed this name into that of St. Nicholas, more generally adopted in the Levant. On the other side is a tower, not so high, nor so strong, which is named St. Angelo's or St. Michael's tower. The harbour is as if divided into two by a small mole, which projects within it, and forms an inclosure, into which boats alone can enter, and which, on that account, is called Boat harbour. Independently of the large harbour, there was another on each side; the one was the harbour for galleys, where they can no longer enter at this day; the other is choked up, and almost entirely dry. Every thing, says Sonnini, is destroyed; every thing is annihilated under a government, which knows only to enjoy, or rather to abuse the present, and to which the most simple calculations of foresight are unknown. Yards for shipbuilding, which might, with so much reason, be called workshops of dilapidation, are established at Rhodes for the Ottoman navy; the timber is brought from the fine and vast forests of Caramania, and even from those of the island. But the construction of ships is so slow, and the timber so injudiciously selected, that they are sometimes half-rotten before they are entirely finished.

In several places of the city of Rhodes are still to be seen marks of the ancient possession of the order of St. John of Jerusalem; a long street preserves the name of Rue des Chevaliers; it is perfectly straight, and formed of old houses, in which remain the armorial bearings of the members of the order. The ancient church of St. John is become the principal mosque; the hospital has been transformed into public granaries; and the palace of the grand master, falling into ruins, is almost entirely deserted. N. lat.  $36^{\circ} 25'$ . E. long.  $27^{\circ} 45'$ .

RHODES, a town of Africa, in the kingdom of Tunis, situated on an eminence, between the lake of Tunis and the sea, at a distance from some hills, where Hanno was defeated by Regulus.

RHODES, *Colossus of*. See COLOSSUS.

RHODES, *Straits of*. See MALTA.

RHODEZ. See RODÉS.

RHODIA, in *Botany*. See RHODIOLA.

RHODIGINUS, CÆLIUS, in *Biography*, a learned Italian, whose proper name was Ludovico Celio Richeri, was born at Rovigo about the year 1450. He studied at Ferrara and Padua, and then travelled into France, in which country he resided a considerable time. On returning to Italy, he filled the office of public professor in his native place from 1491 to 1497, and again obtained the same appointment in 1503; after this he opened a school at Vicenza, where he continued till 1508, when he was invited to Ferrara by duke Alfonso I. In the year 1515, Francis I. nominated him to the chair of Greek and Latin eloquence in Milan, as successor to Demetrius Chalcondylas. He returned in 1521 to Padua, and in 1523 he was re-admitted to the council of his native city, and deputed from it to Venice, to congratulate the new doge. So great was his loyalty, or his gratitude, that, in 1525, he died of grief, on account of the defeat and capture of Francis at the battle

of Pavia. He was author of various works; of these, the principal is entitled "Antiquæ Lectiones," of which he published sixteen books, and fourteen more were added after his death. It was printed at Basil in 1566, and again at Franckfort in 1666. It has been characterised as a miscellany of profound erudition, in which abstruse words in Greek and Latin are explained, obscure passages in the best authors are elucidated, and corrupt ones rectified; recondite histories and ancient rites are narrated, and many arcana of the deepest philosophy, especially of the Platonic school, are brought to light; "whence," says the learned Vossius, "I am often moved with wonder, and indeed with indignation, in observing that the precious labours of such a man are so little in the hands of the youth of the present time." By Julius Scaliger he was denominated "the Varro of the age." Gen. Biog.

RHODIOLA, in *Botany*, from *ῥόδον*, a rose, because the root of this plant, when dried, has a rose-like smell. RHODIOLA is literally the diminutive of RHODIA, a name applied by ancient writers to the wood or root of some plant (suspected by Linnæus to be a *Convolvulus*) possessing a similar fragrant property.—Rose-Root.—Linn. Gen. 526. Schreb. 693. Willd. Sp. Pl. v. 4. 807. Mart. Mill. Dict. v. 4. Sm. Fl. Brit. 1082. Ait. Hort. Kew. v. 5. 397. Juss. 307. Lamarck Illustr. t. 819.—Class and order, *Diocia Ostrandria*. Nat. Ord. *Succulentæ*, Linn. *Sempervivæ*, Juss.

Gen. Ch. Male, *Cal.* Perianth inferior, four-cleft, concave, erect, obtuse, permanent. *Cor.* Petals four, oblong, obtuse, erect, spreading, twice as long as the calyx, deciduous. Nectaries four, erect, emarginate, shorter than the calyx. *Stam.* Filaments eight, awl-shaped, longer than the corolla; anthers simple. *Pist.* Germens four, superior, oblong, acuminate; styles and stigmas obsolete. *Peric.* abortive. *Seeds* none.

Female, *Cal.* Perianth as in the male. *Cor.* Petals four, generally imperfect, of a coarse texture, erect, obtuse, equal with the calyx, permanent. Nectaries as in the male. *Pist.* Germens four, superior, oblong, acuminate, ending in simple, straight styles; stigmas obtuse. *Peric.* Capsules four, carinate, opening inwardly. *Seeds* numerous, roundish.

Obf. Schreber says (in his Appendix, 839), that professor Dahl having seen specimens of RHODIOLA with perfect flowers, viz. with ten stamens and five pistils, the genus should properly be united to SEDUM. Linnæus, however, in his *Flora Lapponica*, mentions a specimen found in Lapland with perfect flowers; but, at the same time, he tells us, that such flowers are barren, none being fertile, except those true female flowers, on a separate plant, which have no stamens, and but imperfect petals. Hence it appears, that the present plant is truly dioecious in habit, although it may occasionally incline to the perfect structure of SEDUM.

Ess. Ch. Male, Calyx in four parts. Petals four. Nectaries four, notched.—Female, Calyx and nectaries like the male, but somewhat smaller. Petals of a coarse texture. Capsules four, many-seeded.

1. *R. rosea*. Rose-root. Linn. Sp. Pl. 1465. Engl. Bot. t. 508. Fl. Dan. t. 183.—Found in the clefts of Alpine rocks, and sometimes on rocks by the sea-shore, in different parts of Great Britain; flowering in May and June.—*Root* perennial, fleshy, white or greyish, when dried emitting a fragrance like that of rose-water. *Stems* perfectly simple, erect, a span high, thickly beset with leaves. *Leaves* imbricated, sessile, obovate, acute, fleshy, glaucous, smooth, toothed towards the top, in the male tipped with red. *Cyme* terminal, sessile, much branched, composed of numerous yellow flowers, the female ones dotted with red.

—It should be remarked, that the odour of the root is greatly impaired by culture.

Miller cultivated a variety of this plant for many years at Chelsea, which was smaller in all its parts, and had purplish flowers.

We can by no means admit *Rhodiola biternata*, Loureir. Cochinch. 627, because that author had never seen the female flowers; and his description of its twining stem, and doubly-compound leaves, renders it in habit so totally unlike the original *Rhodiola*.

RHODIOLA, in *Gardening*, comprises a plant of the low herbaceous, odoriferous, succulent, perennial kind, of which the species cultivated is the common, or yellow rosewort (*R. rosea*).

Of which there is a variety, in which the roots are smaller; the stalks small, and not above five inches long; the leaves small, ending with a purple point; the petals are purplish, and the stamens little longer than the petals. It flowers later than the common sort.

*Method of Culture.*—This plant may be increased by planting cuttings of the stalks in the beginning of April, soon after they come out from the head, in a shady border; covering them close down with a glass, and keeping them dry, when they mostly put out roots in about six weeks; but the cuttings should be laid in a dry room at least a week before they are planted out, otherwise they are apt to rot and be destroyed. They may also be raised by parting the roots in the beginning of autumn, when the stalks begin to decay; and when the fleshy parts are cut or broken, they should be laid to dry a few days before they are planted. They require a shady situation, and a dry undunged soil, in which they will continue many years. They afford variety in the borders, clumps, &c.

RHODITES LAPIS, the *Rose-stone*, in *Natural History*, the name given by authors to a kind of alstroites, or star-stone, in which the figures more represent roses than stars; they are in both owing to coralloide bodies immersed in the stone; which, according to their various species, afford a different figure, when cut transversely, in cutting the stone into plates for use.

RHODIUM, in *Chemistry*, a new metal, found in crude platina, so called from the rose-colour of a dilute solution of the salts containing it, by Dr. Wollaston, to whose inquiries we are indebted for proof of its existence, and an account of its properties. This metal is thus procured: some crude platina being digested in moderately dilute nitro-muriatic acid, a brownish-red solution is obtained; from this the platina is to be separated, for the most part, by muriate of ammonia, and the residual liquor is to be heated with zinc; by this treatment a black powder will be obtained, and the supernatant fluid will consist of the muriates of zinc and iron. This black powder, by digestion in very dilute nitric acid, will be freed from the copper and lead which it usually contains, and the residue is to be digested in dilute nitro-muriatic acid, till every thing soluble is taken up. To this solution a little common salt is to be added, and the whole evaporated to dryness; after which, by repeatedly washing with warm alcohol, the soda-muriates of platina and palladium will be dissolved, leaving behind a pure soda-muriate of rhodium.

This salt is readily soluble in hot water, and deposits on cooling rhomboidal crystals of a bright rose-colour. Sal ammoniac occasions no turbidness in the solution; but if a few drops of muriate of platina are added to the mixture, an immediate yellow precipitate is thrown down. Neither prussiat of potash, nor hydro-sulphuret of ammonia, nor the carbonated alkalies, produce any precipitate; but the pure alkalies throw down a yellow oxyd, soluble either in alkalies or acids. The muriate of this metal is an uncrystallizable

salt of a rose-colour, and soluble in alcohol; with nitre, or the muriates of ammonia or soda, are formed crystallizable triple salts insoluble in alcohol.

Nitrate of rhodium is also uncrystallizable. It appears not to be decomposable by silver, but is so by copper, mercury, and most of the other metals.

The soda-muriate of this metal affords a black powder by digestion with zinc; which, when heated with borax, acquires a white metallic lustre, but is infusible by any heat that has hitherto been applied. It is, however, fusible, either with arsenic or sulphur, and may be again separated from those substances by heat, but it does not acquire by this treatment any degree of malleability. It combines with most metals, and with silver and gold forms very malleable alloys, which are unaltered by a high heat, but become encrusted with a black oxyd when slowly cooled; an alloy of six parts of gold and one of rhodium differs but little in colour from fine gold, but is much more difficultly fusible. The specific gravity of rhodium appears to be somewhat more than 11. That of an alloy consisting of one part rhodium and about two parts lead, was 11.3; which is so nearly that of lead itself, that each part of this compound may be considered as having about the same specific gravity. Phil. Trans. for 1804, vol. xciv. pt. 2. See PALLADIUM and PLATINA.

RHODIUM Lignum. See ASPALATH.

RHODIUM Marmor, a name given by the ancients to a marble brought from Rhodes; it was a good white, but inferior to the Parian, and was used by the Romans in their public buildings, and sometimes in statuary.

RHODIUS, in *Geography*, a river of European Turkey, which takes its source N.E. of mount Ida; and after receiving some rivulets which flow from the neighbouring mountains, and traversing a space of twelve or fifteen miles, discharges itself into the Hellespont, by the side of the castle of Dardanelles. Its waters, which are far from being abundant in summer, are kept back and employed in the irrigation of the lands; but in winter, swelled by the rains which are frequent in that season, it occupies a bed sufficiently large to deserve the name of river. The inhabitants of the Dardanelles, built on its banks, have constructed a wooden bridge, at some distance from its mouth, in order to be able to cross at all times to the left bank, and repair to the fields which they cultivate beyond it. Behind the castle, between the town and the river, is a tolerably extensive walk, naturally turfed, and shaded by very tall plane-trees. This river waters an extremely fertile valley, formed by a plain to the east of the town. In this town are reckoned scarcely 4000 inhabitants, Greeks, Mussulmans, and Jews. Its position is agreeable, its territory is fertile, and its productions are very diversified. To the N.E. is a rising ground, covered with vines; and at the extremity of the fore-mentioned valley are found indications of a volcano; among others are to be seen considerable blocks of granite, the quartzose part of which is almost converted into glass. A little farther on is a fertile and circular bottom of small extent, surrounded by mountains covered with wood.

In the territory of the Dardanelles are cultivated cotton, sesamum, various kitchen-garden plants, the vine, the olive-tree, and several species of fruit-trees. The orange-trees begin to grow here in the open air; and a tolerable large quantity of grain is collected here. The neighbouring mountain furnish the "velanida," (see *QUERCUS Ægilops*,) and gall-nut used in trade. Olivier.

RHODIUS, in *Ichthyology*, the *ACIPENSER Sturio*. See STURGEON.

RHODODENDRA, in *Botany*, a natural order of plants, named after its principal genus, (see the next article,) and

and constituting the fiftieth in Jussieu's series, or the second of his ninth class; for the characters of which class see ERICÆ and GUAIACANÆ. The following are the marks of the order in question.

*Calyx* divided, permanent. *Corolla* inserted into the bottom of the calyx; sometimes of one petal, and lobed; sometimes almost polypetalous, the limb being so very deeply divided. *Stamens* definite, distinct; in the monopetalous genera inserted into the corolla; in the rest into the base of the calyx. *Germen* superior; style one; stigma simple, often capitate. *Capfulæ* superior, of several cells, and several valves, both margins of each valve inflexed, and connected with the central axis, (or *columella*,) so that each forms a cell, containing numerous minute seeds. *Stem* shrubby, more or less lofty. *Leaves* alternate, or more rarely opposite; the young ones, in many instances, revolute at the margin.

Section 1. *Corolla monopetalous.*

*Kalmia*, *Rhododendrum*, and *Azalea*; all Linnæan genera; to which is to be added MENZIESIA; see that article.

Section 2. *Corolla imperfectly polypetalous.*

*Rhodora*, *Ledum*, *Befaria*, (now more correctly written *Bejaria*, by Ventenat and others; the Spaniards having pointed out the error, which originated in a mistake of Linnæus, in reading Mutis's manuscript,) and *Itea*; all likewise Linnæan genera.

Jussieu considers the *Rhododendra* as essentially distinguished from his *Ericæ*, by the want of horns to the anthers, and especially by the inflexed margins of the valves of the capsule. It does not appear to us that these characters are, either of them, strictly absolute. Mr. Salisbury has long ago observed, that the leaves of the *Rhododendra* have always a remarkable glandular tip.

RHODODENDRUM, from ῥόδον, a rose, and δένδρον, a tree, a name adopted by Linnæus from Dioscorides, who ῥοδοδάκτυλον however is but a synonym to his ἑριον, our *Nerium*, or Rose-bay; the ῥοδοδάκτυλον of the modern Greeks.—Linn. Gen. 218. Schreb. 294. Willd. Sp. Pl. v. 2. 603. Mart. Mill. Dict. v. 4. Ait. Hort. Kew. v. 3. 49. Pursh v. 1. 297. Juss. 158. Lamarek Illustr. t. 364. Gærtn. t. 63.—Class and order, *Decandria Monogynia*. Nat. Ord. *Bicornes*, Linn. *Rhododendra*, Juss.

Gen. Ch. *Cal.* Perianth inferior, in five deep segments, permanent. *Cor.* of one petal, widely funnel-shaped; its limb spreading, with five rounded unequal segments. *Stam.* Filaments ten, thread-shaped, about the length of the corolla, declining; anthers incumbent, oval, abrupt, of two cells, opening by two terminal pores. *Pist.* Germen with five angles, abrupt; style thread-shaped, the length of the corolla; stigma obtuse. *Peric.* Capsule ovate, somewhat angular, of five or ten cells, formed by the inflexed margins of the valves, which finally separate from the five or ten-angled central column. *Seeds* numerous, minute.

Eff. Ch. *Calyx* inferior, in five divisions. *Corolla* of one petal, somewhat funnel-shaped, irregular. *Stamens* declining. *Capfulæ* of five or ten cells; partitions from the inflexed margins of the valves.

1. *R. ferrugineum*. Rusty-leaved Rhododendrum. Linn. Sp. Pl. 562. Willd. n. 1. Ait. n. 1. Jacq. Obs. fasc. 1. 26. t. 16. Austr. t. 255.—Leaves smooth; rusty beneath. Clusters terminal. Corolla with a cylindrical leprous tube. *Calyx* fringed.—Native of heathy plains on the alps of Switzerland, Savoy, Austria, Siberia, and the Pyrenees, flowering in August. It is not difficult of culture with us, in bog earth, on an open border, and is one of the most elegant of shrubs. The stem is about two feet high, very bushy. *Leaves* evergreen, stalked, alternate, elliptic-ob-

long, an inch or an inch and a half in length; convex, smooth, and dark shining green above; rusty beneath, but destitute of all pubescence. *Flowers* above half an inch long, in terminal roundish clusters; their *corolla* of a peculiarly rich and beautiful crimson, externally dotted with white. Haller says there is a rare white-flowered variety. The plain of mount Cenis glows with the rich blossoms of this plant in July and August, exhibiting one of the most lovely scenes in nature. See Smith's Tour on the Continent.

2. *R. birjacum*. Hairy Rhododendrum. Linn. Sp. Pl. 562. Willd. n. 4. Ait. n. 3. Jacq. Austr. t. 98. (Ledum alpinum; Clus. Hist. v. 1. 82. Ger. Em. 1290. Balsamum alpinum Gesneri; Lob. Ic. 367.)—Leaves elliptic-obovate, sharpish, fringed; dotted beneath. Corolla with a cylindrical leprous tube.—Native of the Swiss and Austrian alps. Cultivated, like the former, in this country; flowering rather earlier. This is most nearly related to *R. ferrugineum*, next to which therefore we prefer placing it. The chief distinction consists in the leaves being fringed with rigid hairs; their form more obovate and flat, and their under side less rusty. We never could perceive much difference in the flowers, except perhaps those of *birjutum* being rather paler, and more of a pink hue.

3. *R. dauricum*. Daurian Rhododendrum. Linn. Sp. Pl. 562. Willd. n. 2. Ait. n. 2. Pall. Ross. v. 1. t. 32. Curt. Mag. t. 636. Andr. Repof. t. 4. (Chamærhododendros folio glabro majusculo, amplo flore roseo; Amm. Ruth. 181. t. 27.)—Leaves elliptic-oblong, dotted, naked. Corolla nearly wheel-shaped.—Native of Siberia, in mountainous situations. It succeeds in our gardens with the same treatment as the two foregoing, but flowers much earlier, and though evergreen in its own country, is less perfectly so with us; requiring moreover some shelter for its blossoms, during the severity or uncertainty of our winter or early spring. The leaves are dotted on both sides with minute scales, and their midrib is, when young, a little downy. *Flowers* rose-coloured, nearly sessile; their corolla widely expanded, with scarcely any tube, its outside slightly hairy, not leprous. Mr. Andrews seems to have printed "*petiolis longissimis*," by mistake for "*brevissimis*," as the *footstalks* are in fact very short.

4. *R. camtschaticum*. Barberry-leaved Rhododendrum. Pall. Ross. v. 1. p. 1. 48. t. 33. Willd. n. 3. (Chamærhododendros berberis folio, flore amplo roseo; Gmel. Sib. v. 4. 126.)—Leaves obovate, fringed, smooth, reticulated with veins. Corolla wheel-shaped. Found by Steller, in mountainous spots in Beering's island, and the north-east part of Kamtschatka, flowering in July and August. The shrubby stems are procumbent, branched, about a foot long. *Leaves* stalked, obovate, an inch or more in length, blunt, with a very small point, fringed at the margin, but smooth on both sides, destitute of dots or scales, of a thin texture, strongly and copiously reticulated with interbranching ribs and veins. *Flowers* rose-coloured, larger than the last, being nearly two inches wide, each on a long, solitary, hairy, terminal stalk. *Segments* of the calyx flat, oblong, obtuse, ribbed and veiny, sometimes very hairy externally, sometimes only fringed at the edges. This very showy plant is mentioned in Mr. Aiton's Epitome of Hort. Kew. 373, as having come into the hands of our cultivators in 1799, but we have never met with it in any garden.

5. *R. Chamæcistus*. Thyme-leaved Rhododendrum. Linn. Sp. Pl. 562. Willd. n. 5. Ait. n. 4. Jacq. Austr. t. 217. Curt. Mag. t. 488. (Ledum foliis serpilli, ad margines ciliis instar pilosis, flore purpureo; Michx. Gen. 225. t. 106. Cistus humilis austriaca Clusii; Ger. Em. 1278.)—Leaves obovate, acute, fringed, polished, almost veinless. Corolla wheel-

## RHODODENDRUM.

wheel-shaped.—Native of the alps of Aultria, Carniola, and the north of Italy. First raised from seed in England, in 1786, by the skilful Mr. Loddiges of Hackney. A shrubby nearly procumbent plant, much smaller than the last, and differing essentially in the more thick and coriaceous texture of its *leaves*, which are of a dark green, and highly polished, with scarcely any visible veins. The elegant purple *flowers* are not above an inch broad. Their *calyx* has hairy, convex, not flat, segments. Anthers deep purple.

6. *R. caucasicum*. Caucasian Rhododendrum. Pall. Ross. v. 1. p. 1. 46. t. 31. Willd. n. 6. Ait. n. 5. Curt. Mag. t. 1145.—Stem decumbent. Leaves rugged above; downy and rusty beneath. Umbels terminal. Corolla nearly wheel-shaped.—Native of the loftiest summits of mount Caucasus, near perpetual snow, where, according to Pallas, nothing else, besides Whortle-berries and Juniper, grow. Introduced at Kew, by sir Joseph Banks, in 1803. Mr. Loddiges finds it flower more freely under his care than the following. A low shrub, spreading on the ground, but of a stouter habit, with larger more coriaceous foliage, than any of the foregoing. The *leaves* are elliptical, stalked, three or four inches long; convex and of a dark shining green, with a rugose surface, above; concave, veiny, and covered with fine rusty down, underneath. *Footstalks* also downy. *Flowers* large, moderately concave; white or pale flesh-coloured within, their upper segments dotted about the base with green; the outside crimson. They form terminal *umbels*, with large, oblong, concave, permanent *bracteas* at the base.

7. *R. chrysanthum*. Yellow Rhododendrum. Linn. Suppl. 237. Willd. n. 7. Ait. n. 6. Pall. Ross. v. 1. p. 1. 44. t. 30. (*R. officinale*; Salis. Parad. t. 80. Andromeda, n. 9; Gmel. Sib. v. 4. 121. t. 54.)—Stem decumbent. Leaves reticulated, smooth on both sides; paler beneath. Umbels terminal. Corolla nearly wheel-shaped. Native of the mountains of Siberia, Kamtschatka, and Beering's island. Introduced by Mr. Joseph Buxh, in 1756, into our gardens, where it flowers, though rarely in the middle of summer, like the last. Some have imagined these two species to be varieties of each other; but the present differs essentially in having the *leaves* quite smooth and naked beneath, not to mention the uniformly yellow colour of the *flowers*. An infusion of the young leaves is much celebrated in Russia as a cure for the rheumatism. This medicine is taken internally, to promote perspiration. Some have recommended it for venereal complaints. Willdenow justly observes, that this shrub is altogether different from *R. dauricum*, to which the younger Linnæus, by some strange mistake, compares it.

8. *R. ponticum*. Purple Rhododendrum. Linn. Sp. Pl. 562. Willd. n. 8. Ait. n. 7. Jacq. Ic. Rar. t. 78. Pall. Roll. v. 1. p. 1. 43. t. 29. Curt. Mag. t. 650. Andr. Repof. t. 379. (*Chamærhododendros pontica maxima*, folio laurocerasi, flore cæruleo-purpurascente; Tourn. Voyage, v. 2. 99.)—Leaves oblong, smooth and even on both sides. Corymbs terminal. Segments of the calyx oval, obtuse. Corolla bell-shaped, spreading.—Native of the Levant, in moist shady places. Common in the European gardens, where it blooms magnificently in the open ground in June, and, by forcing in a pot, may be had much earlier, as almost every window and balcony in London evinces. This shrub is usually five or six feet high, with brown spreading *branches*. The *leaves* are evergreen, a span in length, elliptic-lanceolate, or oblong, more or less acute; shining, dark green, even and smooth above; equally smooth, but paler beneath, contrary to Willdenow's definition. The large purple *flowers* grow, many together, in large, terminal, corymbose clusters. The gardeners obtain mule varieties,

some of them with deciduous leaves, between this plant and the Azaleas. Tournefort thought the poisonous quality of the honey about Pontus, mentioned by ancient authors, might be partly owing to this plant; at least this seems to be what produced a sort of honey called *Mæonemenon*, because, as Pliny relates, it took away the reason of those who ate it. What is generally reported of the honey of Pontus appears, however, by what Tournefort has collected, to belong to that yielded by *Azalea pontica*, our beautiful yellow Azalea; and this is confirmed by what the Turks told him of the dangerous effluvia of the flowers of this last mentioned plant.

9. *R. arboreum*. Indian Tree Rhododendrum. Sm. Exot. Bot. v. 1. 9. t. 6.—Leaves elliptic-lanceolate; smooth and shining above; downy beneath. Corymbs terminal. Capsule of ten cells. Stem arboreous.—Found by lieutenant-colonel Hardwicke, in the Sewalic chain of mountains, which separates the plains of Hindoostan, from the Himmaleh mountains. It generally grows in forests of oak, in elevated situations, where the soil is black vegetable mould, on a stony bed. The flowers appear in March and April; the seeds are ripened in May or June. The natives know this tree by the name of *Boorans*, and use the wood for the stocks of musquets. The *stem* is truly arboreous, rising in a columnar form to the height of twenty feet; its diameter being from sixteen to twenty-four inches. The *bark* is light as cork, flaking off in large portions. *Branches* ascending, crooked and brittle, leafy at their extremities. *Leaves* shaped much like the last, but distinguished by the dense, white, silky downiness of their under surface. *Flowers* in large terminal clusters, of a rich deep crimson, of little fragrance and short duration, their *corolla* shaped much like the last, but we do not find it spotted within. Segments of the *calyx* shallow. *Germen* elliptical, white and downy, with ten furrows. *Capsule* of the same shape, with ten cells, an unique instance, as far as we know, in the present genus; but certainly, all things considered, not authorising any generic separation of this species from the rest. We know not whether the seeds of this noble tree have vegetated in England. It would probably succeed in the moderate warmth of a conservatory.

10. *R. maximum*. Laurel-leaved Rhododendrum. Linn. Sp. Pl. 563. Willd. n. 9. Ait. n. 8. Pursh n. 1. Curt. Mag. t. 951. (*R. foliis nitidis ovalibus*, &c.; Trew Ehret. t. 66. *Kalmia foliis lanceolato-ovatis*, &c.; Mill. Ic. t. 228.)—Leaves oblong; convex and reticulated above; smooth and pale beneath. Corymbs surmounted by the branches. Segments of the calyx oval, obtuse. Corolla bell-shaped, spreading.—Native of mountainous situations in North America, near rivulets and lakes, flowering from June to August. *Pursh*. Though, according to Mr. Aiton, introduced by Peter Collinson in 1736, twenty-seven years before the *ponticum*, it is beyond comparison less common in our gardens. Botanists have not very clearly defined the specific difference between these two species. The *leaves* of the present are most convex, and more sensibly reticulated with minute sunk veins, on their upper side, while the under is still more pale, than in *ponticum*. The *flowers* of the *maximum* are more delicately coloured, having the red and white tints of an apple-blossom, while the green and yellow dots on their upper segment are strikingly conspicuous. All their segments are more elliptical, concave, and far less dilated and wavy than in *ponticum*. The *inflorescence* moreover is almost umbellate, and more dense, standing between two branches of the present year, which always rise considerably above it. There are mule varieties in the gardens between these species. Mr. Pursh mentions two American varieties, or perhaps species: one with flatter *leaves*, and smaller

smaller whitish flowers: the other much taller, even twenty feet high, with large purple *flowers*, and much larger *leaves*, whose two sides are more alike in colour than the common *maximum*. This last variety, which we too have seen in Mr. Vere's curious garden at Kensington Gore, merits further examination, having certainly more resemblance to *ponticum* than to *maximum*, except its gigantic stature, which far exceeds both.

11. *R. punctatum*. Carolina Dotted-leaved Rhododendrum. Willd. n. 10. Ait. n. 9. Pursh n. 2. Andr. Repof. t. 36. Venten. Jard. de Cels, t. 15.—Leaves elliptic-oblong, acute; smooth above; sprinkled with minute resinous dots beneath. Umbels surmounted by the branches. Segments of the calyx rounded, very short. Corolla funnel-shaped, leprous externally.—Native of the mountains of South Carolina, from whence it was brought to England by the late Mr. John Frazer, in 1791. It succeeds well in our gardens on a peat border, flowering early in the summer. This is a much humbler shrub than any of the varieties of the *maximum*, though its mode of inflorescence accords with that species. The *corolla* is rose-coloured, dilated and wavy as in *R. ponticum*, but smaller; its outside rough or glandular, as in the *ferrugineum*. The *leaves* are elliptical, coriaceous, acute at both ends; dark green and very smooth above; paler, somewhat rusty, and very thickly besprinkled with glandular resinous dots, beneath.

12. *R. catawbiense*. Catawba Rhododendrum. Michaux Boreal-Amer. v. 1. 258. Pursh n. 3. Ait. Hort. Kew. Epit. 373. Curt. Mag. t. 1671.—Leaves oval, rounded at each end, smooth, paler beneath. Umbels surmounted by the branches. Segments of the calyx elongated. Corolla bell-shaped.—Native of the high mountains of Virginia and Carolina, particularly on the head waters of the Catawba river, flowering in May and June. *Pursh*. Mr. Frazer introduced it here in 1809, and brought a report of the *flowers* being scarlet; but they have since proved of a pale purplish rose-colour, with very slight traces of those green dots within, which make so great a part of the beauty of *R. maximum*. The *shrub* is of a very humble size, hardly three feet high, and flowering before it attains even that height; but all its parts are large. The *leaves* are broad, coriaceous, rounded and blunt at both ends; paler beneath, and very obscurely dotted on the veins. The segments of the *calyx* are said to be remarkably elongated, an essential mark of distinction, which ought to have been shewn in the, otherwise excellent, figure. We cannot help wishing also that the uncouth name, given by Michaux, had not been retained; but who shall cleanse the Augean stable of modern botanical nomenclature?

RHODOBENDRUM, in *Gardening*, contains plants of the hardy, deciduous, and evergreen, flowering, shrubby kinds, the dwarf rose-bay, of which the species cultivated are, the rusty-leaved rhododendrum (*R. ferrugineum*); the hairy rhododendrum (*R. hirsutum*); the dwarf rhododendrum, or rose-bay (*R. chamæcistus*); the purple rhododendrum (*R. ponticum*); and the broad-leaved rhododendrum (*R. maximum*).

*Method of Culture*.—These plants may be increased by sowing the seeds, which are very small, as soon as possible after they are procured, either in a shady border, or in pots filled with fresh loam, having them very lightly covered with a little fine mould, and plunging the pots up to their rims in a shady border, and in hard frost covering them with bell or hand-glasses; taking them off in mild weather. When they are sown early in autumn, the plants come up the following spring, when they must be kept shaded from the sun, especially the first summer, and duly refreshed with water; in the autumn following removing them to a shady

situation, on a loamy soil, covering the ground about the roots with moss, to guard them from the frost in winter and keep the ground moist in the summer season. They may also be increased from suckers or offsets, which they produce plentifully where they grow naturally, but seldom in this climate.

And they are very ornamental in the border, clumps, and other parts of shrubberies.

RHODOBENDRUM *Crysanthemum*, golden-flowered rhododendrum, in the *Materia Medica*. The leaves of this species are used in medicine. They are inodorous, and have an austere, astringent, bitterish taste. Water extracts their virtue either by infusion or decoction. These leaves are reckoned stimulant, narcotic, and diaphoretic. Upon being taken, they first increase the arterial action and heat of the body, producing diaphoresis, which effects, according to Dr. Home, are followed by a proportional diminution of excitement: the pulse in one case having been reduced 38 beats. In large doses, they produce nausea, vomiting, purging, delirium, and all the symptoms of violent intoxication. The plant and its effects were first described by Gmelin and Steller in 1747, as a Siberian remedy for rheumatism; but it was not much noticed till after 1779, when Kæmpfer strongly recommended it in this disease, and also in gout and lues venerea. It has not been much used in this country; but from the result of some trials of it in Scotland, it obtained a place in the Edinburgh Pharmacopœia. It has been given in the form of decoction, made by boiling ʒiv of the leaves in fʒx of water, in a close vessel, over a slow fire, for 12 hours. The dose of the strained liquor is from fʒj to fʒij given twice a day, and generally increased. *Woodv. Med. Bot. Thomson's Lond. Dif.*

RHODOLÆNA, in *Botany*, from ῥόδον, a rose, and χλαῖνα, a cloak, or outer covering; a genus so named by Aubert du Petit-Thouars, in his *Plantes des Isles d'Afrique*, fasc. 3, because of the fine rose colour of the flowers, which are said to be very large and splendid. *De Theis*.

RHODOMAN, LAWRENCE, in *Biography*, a learned German, was born, in 1546, at Saffowerf, in Upper Saxony. He studied at the college of Ilfeld, and acquired such a knowledge of classical literature, that he became an able instructor both in public and private. He taught in several seminaries of learning, and was professor of Greek at Jena seven years, and of history at Wittenberg for four years. He died in 1606, at the age of 60. He was deeply learned in the Greek language; but his chief service to literature was by his Latin version of Diodorus Siculus: he was author of a history of Martin Luther, in Greek verse, and many other pieces. *Bayle*.

RHODOMELON, a name given by the ancients to a confection made of roses, quinces, and honey, used as a grateful astringent and detergent in many cases.

RHODON, in *Pharmacy*, from ῥόδον, rosa, a name applied to some compositions, where roses are the chief ingredient, as *diarrhodon*, &c. Hence also *rhodofaccharum*, i. e. *sugar of roses*. See ROSE.

RHODOPE, in *Biography*, a famous courtesan and player on the flute, in antiquity, was born in Thrace. She was at first a slave in the same house as *Æsop*. Charaxus, the brother of Sappho, was violently enamoured of her, and having purchased her, gave her her liberty. She established herself at Mucrates, where she became a courtesan, and amassed immense riches. *Pliny* says that she built, at her own expence, the most beautiful of the Egyptian pyramids; but *Herodotus*, and *Bayle* from his authority, reject this tale; nor do they give any more credit to the following story.

One day, when she was bathing, and her attendants watching

watching her clothes, an eagle pounced upon one of her shoes, and carrying it away, flew with it to Memphis, where he let it fall near king Psammiticus. This prince, admiring the beauty of the shoe, ordered the officers of his household to seek, throughout all Egypt, the person to whom the shoe appertained. She was found and brought to him; and he espoused her. But how are we to reconcile this fact with her being married to Æsop? It is, however, certain, say the Encyclopædists, that this fabulist, notwithstanding his deformity and ugliness, had the art to make himself beloved by her.

**RHODOPUS GALLINULA**, in *Ornithology*, a name given by some authors to the bird more usually known by the name *tringa*.

**RHODORA**, in *Botany*, so called by Linnæus, from *ῥόδον*, a rose, in allusion to the colour of its flowers, and probably, at the same time, to preserve an analogy with its near relation *Rhododendrum*.—Linn. Gen. 218. Schreb. 294. Willd. Sp. Pl. v. 2. 603. Mart. Mill. Dict. v. 4. Ait. Hort. Kew. v. 3. 49. Pursh v. 1. 298. Juss. 159. Lamarck Illustr. t. 364. Class and order, *Decandria Monogynia*. Nat. Ord. *Bicornes*, Linn. *Rhododendra*, Juss.

Gen. Ch. *Cal.* Perianth inferior, minute, of one leaf, with five teeth, permanent. *Cor.* Petals three, unequal; the two lowermost lanceolate, equal; the upper one wedge-shaped, ascending, three-lobed, the middle lobe rather longest. *Stam.* Filaments ten, thread-shaped, declining, the length of the corolla; anthers rounded, two-lobed. *Pist.* Germen ovate, furrowed, superior; style thread-shaped, declining, rather longer than the stamens; stigma thickest, abrupt, convex. *Peric.* Capsule ovate-oblong, with five furrows, of five cells and five valves, the partitions from the inflexed margins of the valves. *Seeds* numerous, minute.

Ess. Ch. Calyx five-toothed. Corolla of three petals, unequal. Stamens declining. Capsule superior, of five cells; the partitions from the inflexed margins of the valves.

1. *R. canadensis*. Canadian Rose-blossom. Linn. Sp. Pl. 561. Willd. n. 1. Ait. n. 1. L'Herit. Stirp. v. 1. 141. t. 68. Curt. Mag. t. 474. (*Chamærhododendros*; Duham. Sem. Append. 10. t. 27. f. 2, 3.)—Native of Canada and Newfoundland; very hardy in our gardens, except that, flowering in April and May, its blossoms are often injured. Curtis says it bears gentle forcing remarkably well. Sir Joseph Banks brought this shrub to England in 1767; but it flowered at Paris, for the first time, in March 1756. Duhamel suggested the propriety of establishing it as a new genus, which Linnæus adopted and named; but afterwards, having never seen the plant, he struck it out, nor did he assign any reason for this measure. The accuracy of Duhamel is, at length, confirmed, and the *Rhodora* re-established. The stem is bushy, erect, two or three feet high, with round, smooth, grey or reddish branches, never quite straight. Leaves deciduous, alternate, stalked, elliptical, acute, entire, veiny, hairy, slightly glaucous, about an inch and half long, and half an inch wide. Flowers appearing before the leaves, in terminal solitary umbels, four or five in each umbel, of a bright elegant rose colour, with violet anthers, inodorous. Petals spreading, each an inch long. Capsule clothed with rusty down.

**RHOE**, in *Ancient Geography*, a river of Asia Minor, in Bithynia.

**RHŒADEÆ**, in *Botany*, the 27th natural order, among the *fragmenta* of Linnæus; of which there is no explanation in his *Prælectiones*, published by Giseke. The genera referred hither, at the end of the Gen. Pl., are *Argemone*, *Chelidonium*, *Papaver*, *Podophyllum*, *Sanguinaria*,

*Bocconia*. We place them according to the manuscript corrections of the author, who has subjoined *Cytinus*, *Arif-tolochia*, and *Afarum*.

This order, without the additions, which certainly do not belong to it, is equivalent to the first section of Jusseu's *PAPAVERACEÆ*. (See that article.) Its name is taken from the Greek appellation of the field poppy, *ῥίον*; *Papaver Rhæas* of Linnæus; which was so called from *ῥίον*, to fall off, because of the short duration of its petals.

**RHŒAS**, in *Surgery*, a diminution of the caruncula lachrymalis from disease.

**RHŒTICO**, in *Geography*, a mountain of Germany, in the county of Pludentz; 6 miles S. of Pludentz.

**RHŒTUM**, or **RHŒTIUM**, in *Ancient Geography*, a town of Asia Minor, in the Troade, on the coast of the Hellespont. According to Strabo, it was built on an eminence near the tomb of Ajax. The promontory called "Rhætium" was four miles distant from that of Sigæum.

**RHŒXUS**, a port of Asia, on the coast of Cilicia, at the mouth of the river Sarus. Steph. Byz.

**RHŒZIA**, in *Geography*, a city of Persia, in the province of Mingrelia, situated on the Hippus, the usual residence of the princes of Mingrelia, but which they changed in summer for Taqueria, a very pleasant spot, seven versts S. of Ghoni. In Rhæzia much silk is cultivated; and all that is prepared in the other parts of Mingrelia is also carried thither, to be sold or manufactured. The manufacture, however, of that commodity is not well understood, as they only make a poor sort of handkerchiefs, or common taffeties.

**RHOGE**, in *Ancient Geography*, an island on the coast of Lycia, placed by Pliny in the vicinity of that of Cyprus. Steph. Byz.

**RHOGE**, in *Surgery*, a rupture or fracture.

**RHOGMOI**, in *Ancient Geography*, a port of Asia, on the coast of Cilicia. Steph. Byz.

**RHOGOMANIS**, or **RHOGONIS**, a river of Asia, in the Perside. Ptolemy places the mouth of this river in the southern part of the Perside, on the Persian gulf. According to Nearchus, it was a small river, 200 stadia from the river Granis.

**RHOITES**, the name of a medicine among the ancients, which is a sort of rob of the juice of pomegranates. Dioscorides describes it as the simple juice of the fruit, evaporated over the fire to the consistence of an extract; but Paulus Ægineta gives the receipt to be three parts juice of pomegranate, and one part honey, boiled to the evaporation of a third part. So that the rhoites of Dioscorides was a true rob of pomegranates; the other rather honey of pomegranates, like our honey of roses.

**RHOMB**. See **RHOMBUS**.

**RHOMBITES**, in *Ancient Geography*, a river of Asiatic Sarmatia. Ptolemy.

**RHOMBO**, in *Ichthyology*, the name of a peculiar fish of the rhombus, or turbot kind, called *rhombus aculeatus* by Aldrovand, Gesner, and other writers. It is a large fish, of an ash-coloured green on the back, and white on the belly. It has no scales; but the skin of its back is divided by lines, something in the manner of the skins of snakes. The mouth is very large, and is well furnished with teeth; and the palate has a number of tubercles, armed also with a sort of teeth. It feeds on fish, and its flesh is very delicate. It is very common in the markets at Venice, and is caught in the neighbouring seas, and in many other places. See **PLEURONECTES Maximus**.

**RHOMBOIDÆUS Major** and **Minor**, in *Anatomy*, names given by Albinus to what he makes two muscles, though Winflow and others account it only one. What Winflow

Winflow calls the inferior portion of the rhomboidalis, Albinus calls rhomboidæus major; and what he calls the upper portion of that muscle, Albinus calls rhomboidæus minor. See RHOMBOIDEUS.

RHOMBOIDALIS. See RHOMBOIDEUS.

RHOMBOIDES, in *Geometry*, a quadrilateral figure, whose opposite sides and angles are equal, but which is neither equilateral nor equiangular; or, it is an oblique-angled parallelogram.

Such is the figure NOPQ, *Plate XII. Geometry, fig. 1.* For the method of finding the area of a rhomboides, see RHOMBUS.

RHOMBOIDES, in *Ichthyology*. See CHÆTODON *Argus, Striatus, &c.*

RHOMBOIDEUS, in *Anatomy*, a muscle of the shoulder, so called on account of its shape; dorso-scapulien of Chauffier.

It is a broad, flattened, quadrilateral muscle, placed obliquely at the lower part of the neck and upper part of the back, and extending from the lower portion of the ligamentum nuchæ, and the superior spinous processes of the back, to the basis of the scapula. The whole of its fibres go obliquely from the spine downwards and outwards to the scapula; thus as it is regularly quadrilateral, it has a correct rhomboid figure. Its posterior surface is chiefly covered by the trapezius; the latissimus dorsi lies on a small portion of it below; and between these two muscles its fibres are covered by the skin only. The serratus superior posticus, splenius, longissimus dorsi, sacrolumbalis, the ribs, and the external intercostal muscles, are covered by its anterior surface. Its upper edge goes from the lower part of the ligamentum nuchæ, obliquely outwards and downwards, to the basis of the scapula opposite to the commencement of the spine of the bone. In great part of its extent this edge is in contact with the levator scapulæ. The lower margin reaches from the spinous process of the fourth or fifth dorsal vertebra to the inferior angle of the scapula. The two edges are nearly of equal length, and parallel to each other. The internal edge is attached to the lower portion of the ligamentum nuchæ, to the last cervical spinous process, to the four or five superior dorsal spines, and to the interspinal ligaments of those bones. The outer edge is fixed to the basis of the scapula, from its inferior angle to above the origin of the spine, between the supra and infra spinatus behind, and the serratus magnus in front.

The rhomboides is partly muscular, partly aponeurotic. Its inner edge is attached by aponeurotic fibres, having the same direction as the fleshy one, short above, and longer below. It is fixed to the upper part of the scapula by short aponeuroses; its insertion in the remainder of the basis is by an aponeurosis attached only at its upper and lower extremities, leaving a passage between these points for branches of the transversalis colli artery. The muscular fibres are all directed obliquely from within outwards, and from above downwards.

The muscle is generally divided into two portions, united by cellular tissue to a superior smaller, and an inferior larger one: these are called the rhomboides minor and major.

By drawing the basis of the scapula obliquely upwards and backwards, the rhomboides carries the inferior angle towards the spine, and makes the anterior angle of the bone, constituting the shoulder, roll forwards and downwards. Thus it restores the scapula to its situation after the shoulder has been raised. It concurs in this action with the levator scapulæ.

RHOMBOIDIA, in *Natural History*, the name of a genus of spars, given them from their being of a rhomboidal

form. They owe this figure to an admixture of particles of iron, and consist of six planes.

Of this genus there are only two known species, viz. a white thin one with very thin crusts, and a whitish-brown thick one with thicker crusts. They are both found in the forest of Dean in Gloucestershire, and in other places, where there are iron-ores. Hill.

RHOMBUS, ῥομβος, is formed of ῥομβος, of ῥομβειν, to encompass or turn round, in *Geometry*, an equilateral rhomboid; or a quadrilateral figure, whose sides are equal and parallel, but the angles unequal; two of the opposite ones being obtuse, and the other two acute. Such is the figure ABCD, *Plate X. fig. 11.*

To find the Area of a Rhombus, or Rhomboides.—Upon CD, which is here assumed as a base, let fall a perpendicular AE, which will be the altitude of the parallelogram: multiply the base by the altitude, the product is the area. Thus, if CD be = 456, and AE = 234, the area will be found 106704.

For it is demonstrated, that an oblique-angular parallelogram is equal to a rectangle upon the same base CD, and of the same altitude AE (see PARALLELOGRAM). But the area of a rectangle is equal to the factum of the base into the altitude; therefore the area of an oblique-angular parallelogram is equal to the same. See RECTANGLE.

The area of a parallelogram, rhombus or rhomboides, may be found by means of the following proportion: As radius, i. e. sine of 90° or tangent of 45°, is to the sine of any angle of a parallelogram, so is the product of the sides including the angle to the area of a parallelogram: that is, AD × DC × nat. sine of the angle D = the area. For having drawn the perpendicular AE, the area, by the first rule, is AE × DC; but as rad. 1 (sin. < E) : sin. < D :: AD : AE = sin. < D × AD; therefore AE × DC = DC × sin. < D × AD is the area; or, 1 : sin. < D :: AD × DC : sin. < D × AD × DC = the area of the parallelogram.

N.B. As the angles of a square and rectangle are each 90°, whose sine is 1, this rule is the same as the former.

E. G. 1. What is the area of a rhomboides, whose length is 36 feet, slope-height 25.5 feet, and one of the less angles 58°? Here rad. or 1 : .8480481 (nat. sine of 58°) :: 918 (= 25.5 × 36) : 778.5081558, the area. Or, by using the logarithms, rad. (10.0000000) : sin. 58° (9.9284205) :: log. of 918 (2.9628427) : 778.5081, the number corresponding to the log. (2.8912632).

2. What is the area of a parallelogram whose angle is 90°, and the including sides 20 and 12.25 chains? Ans. 245 acres.

3. What is the area of a rhombus, each of whose sides is 21 feet 3 inches, and each of the less angles 53° 20'? Ans. 362.208757 feet.

4. How many acres are in a rhomboides whose less angle is 30°, and the including sides 25.35 and 10.4 chains? Ans. 13 acres 29.12 perches.

The area of either of the forementioned figures may also be had by the following rule, which is common to all quadrilaterals. As radius is to the sine of the angle which the intersecting diagonals of a parallelogram make with each other, so is the product of the diagonals to double the area:

that is,  $\frac{AC \times BD \times \text{nat. sine of the angle R}}{2}$  = the area.

N.B. Because the diagonals of a square and rhombus intersect at a right angle, whose sine is 1, half the product of their diagonals is the area; that is,  $\frac{1}{2} AC^2$  in the square and  $\frac{1}{2} AC \times BD$  in the rhombus is the area.

E. G.

*E. G.* 1. How many acres are in a piece of land, in the form of a rhombus, whose diagonals are 30 and 20 chains? *Ans.* 30 acres.

2. How many yards of painting are in a rectangle, whose diagonals, intersecting in an angle of 30°, are each 32 feet? *Ans.* 28½.

3. What is the area of a rhomboides, whose diagonals, making an angle of 60°, are 30 and 25 feet? *Ans.* 324.7595 fœt. Hutton's Mensuration.

**RHOMBUS**, *Solid*, two equal and right cones joined together at their bases.

**RHOMBUS**, in *Ichthyology*, a species of the *Pleuronectes*; which see. See also *PLEURONECTES Maximus* and *TURBOT*, and *P. Passer*.

**RHOMBUS**, in *Conchology*, the name given by the generality of authors to a genus of the shell-fish, much more properly called by some *cylindrus*.

**RHOMBUS**, among *Surgeons*, denotes a sort of bandage of a rhomboidal figure.

**RHON**, in *Ancient Geography*, a river of India, among the people called Gandarii. Steph. Byz.

**RHONDE**, in *Geography*. See *RONDE*.

**RHONE**, a river of France, formed by the union of three springs, which rise in mount Susberg, a part of the Grimsell, at the eastern extremity of the Valais. It passes through the lake of Geneva to Seffel, &c. and thence to Lyons, where it joins the Saône, and after watering Vienne, Valence, Viziers, Avignon, Arles, &c. discharges itself by several mouths into the Mediterranean.

**RHONE**, *Mouths of the, Bouches de Rhône*, one of the twelve departments of the S.E. region of France, bounded on the N. by the county of Venaissin, on the N.E. by the department of the Lower Alps, on the E. by the department of the Var, on the S. by the Mediterranean, and on the W. by the department of the Gard: 5315 kilometres in extent, or 269 square leagues, and containing a population of 320,072 persons. It is divided into three circles or districts, including 26 cantons and 108 communes. The circles are, Marseilles, having 142,058 inhabitants; Aix, 97,938; and Tarascon, 80,076. According to M. Hassenfratz, its extent in French leagues is 30 in length and 20 in breadth; its circles are 5, its cantons are 40, and its population consists of 446,643 persons. It is a portion of Lower Provence, and lies in N. lat. 43° 40'. Its capital is Aix. Its contributions to the land-tax, &c. amounted, in the 11th year of the French era, to 3,612,199 fr.; and its expences, administrative, judiciary, and for public instruction, to 354,531 fr. 33 cents. Many of the hills in the northern districts are bare rocks, destitute of soil and verdure. The chief productions of the department are grain, wine, silks, olives, fruits, and pastures. It has mines of iron, alum, vitriol, with quarries of marble, &c. Pools and marshes are dispersed near the coast.

**RHONE**, or *Rhone and Loire*, one of the eleven departments of the E. region of France, bounded on the N. by the department of the Saône and Loire, on the E. by the departments of the Ain and the Iſere, on the S. by the departments of the Ardèche and the Upper Loire, and on the W. by the departments of the Puy de Dôme and the Allier: to the E. it is bounded by the river Rhine, and the Loire passes nearly through its centre from N. to S. Its extent is 2935 kilometres, or 147 square leagues, and its population consists of 345,644 persons. It is divided into 2 circles, 25 cantons, and 261 communes. Its circles are Villefranche, including 106,262 inhabitants, and Lyons, having 239,382. According to Hassenfratz, its extent in French leagues is 20 in length, and 9 in breadth; its circles are 2, its cantons

32, and its population is 323,177. It lies in N. lat. 46° between Ain and Loire, and comprehends the provinces formerly called Lyonnais and Beaujolais. Its capital is Lyons. The plains yield scanty crops of grain and pasture; the gentle eminences are covered with vineyards, and the summits of the mountains are clothed with pines. This department has mines of copper, lead, coal, quarries of marble, freestone, &c.

**RHOPALA**, in *Botany*, a name altered by Schreber from the *Roupala* of Aublet, which, being of barbarous origin, and unexplained by the publisher, he contrived, by the above alteration, to derive from *ροπαλον*, a club, or *flake*. This may very well apply to the size and nature of the woody stem, which rises to the height of three or four feet, before it sends off any branches. Vahl and Willdenow have contrived to retain the barbarism, without adding any thing to the sense.—Schreb. 62. Brown. Tr. of Linn. Soc. v. 10. 190. (*Roupala*; Aubl. Guian. v. 1. 83. Juss. 79. Lamarek Illustr. t. 55. Gært. suppl. t. 217. *Rupala*; "Vahl Synb. v. 3. 20." Willd. Sp. Pl. v. 1. 536.)—Class and order, *Tetrandria Monogynia*. Nat. Ord. *Proteaceæ*, Juss. Brown.

Gen. Ch. *Cal.* none. *Cor.* Petals four, spatulate, regular, concave, recurved at the extremity. Nectary of four glands, separate or combined, at the base of the germen. *Stam.* Filaments four, short, inserted above half way up the petals; anthers oblong, two-lobed, projecting beyond their recurved extremities. *Pist.* Germen superior, ovate, with rudiments of but two seeds; style awl-shaped, permanent, the length of the corolla; stigma vertical, club-shaped, undivided. *Peric.* Follicle ovate, somewhat woody, of one cell. *Seeds* two, bordered, winged at each end, the kernel central.

Ess. Ch. Calyx none. Petals four, regular, recurved. Stamens inserted into the middle of each petal. Nectary of four glands. Stigma vertical, club-shaped. Follicle of one cell. Seeds two, bordered, winged at each end.

The habit of the genus is arborescent. *Leaves* alternate, rarely whorled; simple, entire or toothed, rarely pinnate, or ternate, on the same branch. *Spikes* axillary, sometimes terminal, racemose, the *flowers* in pairs with a single *bractea* to each pair.

1. *R. montana*. (*Roupala montana*; Aubl. Guian. v. 1. 83. t. 32. Lamarek t. 55. *Rupala montana*; Willd. n. 1.)—Leaves alternate, entire, ovate, folded, short-pointed, reticulated with veins. Spikes axillary, solitary, longer than the leaves. Flower-stalks, petals and germen clothed with rusty down.—Native of the Serpent Mountain in Guiana, flowering in August. *Aublet*. A small tree, seven or eight feet high; its trunk three or four feet. *Bark* wrinkled and cracked, whitish, as well as the wood. Both exhale, when cut, a strong fetid scent, like that of the serpents of the same country. *Leaves* smooth, of a firm dry texture, about three inches long. *Footstalks* an inch long, inflated at the base. *Flowers* about eight or ten alternate sessile pairs, in each lax *spike*.

2. *R. media*. Brown n. 2.—Leaves alternate, entire, ovate, flat, pointed, running down the footstalk, with depressed veins. Clusters axillary, solitary, longer than the leaves. Partial flower-stalks and petals somewhat hairy. Germen downy.—Gathered in the same country by Von Rohr, who sent specimens to Sir Joseph Banks. This seems very nearly related to the foregoing.

3. *R. nitida*. Br. n. 3. (*Roupala nitida*; Rudge Guian. v. 1. 26. t. 39.)—Leaves alternate, entire, elliptical, short-pointed, flat. Clusters axillary, solitary, about the length of the leaves. Partial flower-stalks, petals and germen smooth.—Gathered by Joseph Martin in Guiana. *Brown*.

4. *R. moluccana* Br. n. 4.—Leaves alternate, entire, elliptical, flat, finely veined, somewhat reticulated, longer than the clusters. Partial flower-stalks and petals smooth.—Gathered in the Molucca islands, by the late Mr. Christopher Smith. *Herb. Banks.*

5. *R. cochinchinensis*. Br. n. 5. (*Helicia cochinchinensis*; Lour. *Cochinch.* 83, on the authority of a specimen seen by Mr. Brown, in Sir Joseph Banks's collection, from the author.)—Leaves alternate, elliptic-ovate, short-pointed, flat, somewhat ferrated above half way down. Clusters axillary, solitary, about the length of the leaves. Partial flower-stalks, petals and germen smooth.—Native of woods in Cochinchina. (See *HELICIA*.) Mr. Brown observes, that what Loureiro describes as a four-cleft *calyx*, are really the nectariferous glands, united at their base, and remaining after the petals are fallen. Such a mistake might well render his description unintelligible, without a sight of the plant.

6. *R. ferrata*. Br. n. 6.—Leaves alternate, broadly elliptical, scarcely pointed, ferrated; somewhat contracted and entire at the base; paler beneath. Clusters axillary, solitary, shorter than the leaves. Partial flower-stalks, petals and germen downy.—Gathered by Mr. Christopher Smith in the Molucca isles.

7. *R. dentata*. Br. n. 7.—Leaves alternate, ovato-lanceolate, folded, toothed, tapering at each end; with a linear point. Clusters axillary, solitary, rather longer than the leaves. Petals and germen downy.—Gathered by Mr. Alexander Anderfon in Guiana. *Herb. Banks.*

8. *R. peruviana*. Br. n. 8. (“*Embothrium monospermum*; Fl. Peruv. et Chil. v. 1. 63. t. 98.”)—Leaves alternate, ovate, ferrated, woolly; rusty beneath. Clusters axillary, solitary, longer than the leaves.—Native of the colder mountains of Peru.

9. *R. diversifolia*. Br. n. 9. (“*Embothrium pinnatum*; Fl. Peruv. et Chil. v. 1. 63. t. 99.”)—Leaves alternate, simple or pinnate, very veiny; downy beneath. Clusters axillary, solitary, longer than the leaves. Follicles cimeter-shaped, downy.—Native of waste ground, and the borders of fields, in Peru.

10. *R. fessilifolia*. Br. n. 10. (*Roupala fessilifolia*; Richard Act. Soc. Hist. Nat. Par. v. 1. 106. Poiret in Lamarck Dict. v. 6. 316. *Rupala fessilifolia*; Willd. n. 2. *Ropala hamelæifolia*; Rudge Guian. v. 1. 22. t. 31.)—Leaves four in each whorl, nearly sessile, oblong, somewhat wedge-shaped, slightly pointed, entire. Clusters terminal, umbellate. Flowers whorled.—Native of Guiana. The leaves are, in the figure, precisely obovate, tapering at the base, a span long. Clusters about the same length, erect, stalked, forming an umbel at the top of the branch or stem; their partial stalks hairy, imperfectly whorled, very numerous.

**RHOPALIC VERSES**, among the *Ancients*, a kind of verses which began with monosyllables, and were continued in words growing gradually longer and longer to the last, which was the longest of all.

They had their name from the Greek *ῥοπαλον*, a club, which, like them, begins with a slender tip, and grows bigger and bigger to the head. Such is that verse of Homer:

Ω μακρῆς Ἀτρεΐδῃ μοιρηγνῆτες, οὐδ' ἰσοδαίμων.

And this Latin one of Aufonius:

“*Spes deus æternæ stationis conciliator.*”

**RHOPALOSIS**, a distemper of the hair described by the ancients, and seeming to be the same with what we call the *Plica Polonica*; being a sort of matting together of the hair into long and thick tresses.

**RHOPE**, formed of *ῥεπω*, to *preponderate*, a word used by the Greek writers to express a violent tendency of the humours to any particular part of the body.

**RHOPIUM**, in *Botany*, from *ῥαπιον*, a slender shoot, the flower-stalks of this plant having a delicate, twiggy appearance.—Schreb. 608. Willd. Sp. Pl. v. 4. 150. (Meborea; Aubl. Guian. 826. Juss. 437. Lamarck Illustr. t. 731.)—Class and order, *Gynandria Triandria*. Nat. Ord. *Euphorbia*, Juss. See *MEBOREA*.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, permanent, cloven into six, lanceolate, acute segments, each having a little bordered cavity at the base. *Cor.* none. *Stam.* Filaments none; anthers three, cloven, each adhering to a single style under the stigma, with distant cells, bursting transversely. *Pist.* Germen superior, roundish or triangular; styles three, erect, approximated; stigmas flat, acute, bent down over the anthers. *Peric.* Capsule composed of three obtuse-angled lobes, with six cells, and six valves: partitions from the middle of the valves. *Seeds* two, one adhering to each side of the partition, ovate.

Eff. Ch. *Calyx* six-cleft. *Corolla* none. *Anthers* three, with remote cells, and placed in the middle of the styles. *Styles* three. *Capsule* three-lobed, of three cells, each with two seeds.

1. *R. citrifolium*. Willd. (*Meborea guianensis*; Aubl. Guian. t. 323.)—Native of woods in Guiana, where it flowers and bears fruit in January. The stem of this shrub is from three to four feet in height, branched towards the summit. *Leaves* alternate, ovate, acute, smooth, entire, nearly sessile. *Stipulas* twin, small, deciduous. *Flowers* corymbose, axillary and terminal, of a yellowish-green colour, each standing on a long, slender stalk, which is furnished with a scale at its base.

**RHOPOGRAPHI**, *ῥοπογραφοί*, formed of *ῥεπος*, *toys* or *odd ware*, and *γραφω*, *I paint*, in *Antiquity*, an appellation given to certain painters, who confined themselves to low subjects, such as animals, plants, landscapes, &c.

The same appellation has been also given to such as cut figures of men, &c. in box, phillyrea, yew, &c. in gardens.

**RHOSOLOGIA**, in *Ancient Geography*, a town of Asia, in Galatia, in the country of the Teitfages, between Venzala and Sarmalia. Ptolemy.

**RHOSOS**, a town situated on the gulf of Issus, at the eastern extremity of the Mediterranean sea, between two defiles, one of which led to Syria, and was called the “gates of Syria;” and the other formed by mount Amanus and the sea-coast, communicating with Cilicia, and called the “Amanic gates.” Ptolemy places this town in Syria, and Strabo places it in Cilicia. After the death of Seleucus Nicator, Demetrius caused the statue of Fortune to be conveyed thither. It was famous for the manufacture of earthen vessels, mentioned by Cicero, when he was governor of Cilicia, in a letter to Atticus. Sapor, king of Persia, burnt this city, after he had taken prisoner the emperor Valerian, A.D. 260. It was pillaged under the reign of Arcadius, in the year 404, by the Haurians, a savage people, who inhabited the mountains. Jupiter was worshipped in this town; and the statue of this deity was engraven on the medals of Rhosus.

**RHOSSICUS SCOPULUS**, a promontory of Asia, in Syria, near the gulf of Issicus.

**RHOT**, in *Geography*, a river of Switzerland, which runs into the Aar, 5 miles W. of Zoflingen.

**RHOTANUM**, in *Ancient Geography*, a river of Corfica, the mouth of which is placed by Ptolemy on the eastern side, between Valeria Colonia and the port of Diana.

RHOX, a word used by some authors to express the tunica uvea of the eye.

RHUBARB, RHABBARUM, in *Botany*. See RHEUM.

RHUBARB, *Rheum Palmatum*, in the *Materia Medica*. The rhubarb, called the rhabbarum officinale, was supposed, in the year 1732, to be supplied by some plants sent from Russia, to Jussieu of Paris, Rand at Chelsea, and Linnæus at Upsal. Accordingly these plants were adopted by Linnæus, in his first edition of the *Species Plantarum*, under the name of rheum rhabbarum. This, however, was not very generally received as the genuine rhubarb plant. But in order to ascertain this matter more completely, Kaul Boerhaave procured, from a Tartarian rhubarb merchant, the seeds of those plants, which he annually sold, and which were admitted at Peterburgh to be the true rhubarb. These seeds were soon discovered by de Gorter to produce two distinct species; viz. the *R. rhabbarum* of Linnæus, or *R. undulatum*, as it has been since called; and another species, declared by Linnæus to be a new one, and first mentioned in the second edition of the *Species Plantarum*, in 1762, under the name of *R. palmatum*. But before this time, de Gorter had repeatedly sent its seeds to Linnæus, and the young plants constantly perished: at length he obtained the fresh root, which succeeded very well at Upsal, and enabled the younger Linnæus to describe this plant in the year 1767. However, two years antecedent to this, Dr. Hope's account of the rheum palmatum, as it grew in the Botanic garden near Edinburgh, had been read before the Royal Society at London; and of the great estimation in which this plant was held by him we have the following proof. "From the perfect similarity of this root with the best foreign rhubarb in taste, smell, colour, and purgative qualities, we cannot doubt our being at last possessed of the plant which produces the true rhubarb, and may reasonably entertain the agreeable expectations of its proving a very important acquisition to Britain." (See *Phil. Transf.* for the year 1765.) But from the relation above given, it appears that the seeds of both *R. undulatum* and *R. palmatum* were transmitted to Peterburgh as those of the true rhubarb: we are therefore to conclude, that the former species has an equal claim to this importance with the latter; and from further inquiries made in Russia, there is the best authority for believing that the *R. compactum* also affords this very useful drug. Bergius says, "*Rheum palmatum* producit *rhabbarum* in officinis *Sibiricum* appellatum: certe e seminibus a Bucharis e montosis Tibeti in Russiam apportatis, et postea satis hocce rheum palmatum enatum est." (Vide Pallas Reise, &c. vol. iii. p. 157.) "*Rhabbarum* vero *Chinense* ex alia specie rhei desumptum esse videtur." (Vide Georgi Reise, &c. vol. i. p. 211.) The seeds of the rheum palmatum were first introduced into Britain in 1762, by Dr. Mounsey, who sent them from Russia, and were supposed to be a part of those already mentioned; and since their prosperous cultivation by the late professor of botany at Edinburgh, the propagation of this plant has been gradually extended to most of our English gardens, and with a degree of success which promises in time to supersede the importation of the foreign root. The *R. rhaponticum* is a different species from either of these. This is supposed to be the rhabbarum of the ancients. It is well known that the ancient rhubarb had not the purgative virtues of the modern. Two sorts of rhubarb are usually imported into this country for medical use, viz. the Chinese and the Tartary rhubarb. Mr. Bell informs us, in his travels, that the best rhubarb grows in that part of the Eastern Tartary called Mongallia, which serves as a boundary between Russia and China; or,

on the chain of mountains in Tartary, which stretches from the Chinese town Selin to the lake Kokonor, near Thibet. This plant, he says, does not run and spread itself like docks, but grows in tufts at uncertain distances, as if the seed had been dropped with design. As the Mongalls do not think it worth cultivating, the marmots, which burrow under the shade of its spreading leaves, and probably feed on its leaves and roots, contribute to its increase, partly by the manure which their dung affords it, and principally by casting up and loosening the earth, into which the ripe seeds, blown by the wind, fall, and where they immediately take root. After digging and gathering the rhubarb, the Mongalls cut the large roots into small pieces, in order to make them dry the more readily. The roots are taken up in autumn, according to Mr. Bell's account; but according to Pallas, in April and May: and after being cleaned, and cut transversely into pieces of a moderate size, these pieces are placed on tables, and turned three or four times a day for five or six days. In the middle of every piece they scoop a hole, through which a cord is drawn, in order to suspend them in a convenient place, but sheltered from the sun, and exposed to the air and wind; and by this practice they destroy some of the best part of the root.

The proper exsiccation of this root is certainly attended with great difficulty, and the cultivators of rhubarb in this country have not yet agreed as to the best mode of accomplishing it. The recent root, in this process, according to the experiment of sir William Fordyce, loses nearly nine-tenths of its weight; and as others say, seven-eighths. In China the roots are not dug up till winter; and the cultivators, after cleaning, scrape off the bark, and cutting them, dry the slices by frequently turning them on stone slabs, heated by a fire underneath; after which, the drying is completed by hanging them up in the air, exposed to the greatest heat of the sun. Part of the Tartarian rhubarb is carried to Turkey through Natolia; but the greatest part is conveyed by the Bucharians to Kiachta, on the Russian frontier, where it is examined by a Russian apothecary, and the best pieces only are selected and sent to Peterburgh. The Chinese is conveyed to Canton, and there purchased by the agents of the East India Company.

Of the two sorts of rhubarb above mentioned, the Chinese is chiefly obtained in the province of Xensi or Shensee, under the name "Taihoung." It comes immediately from the East Indies, in oblong pieces, flattish on one side, and convex on the other; compact, hard, heavy, internally of a dull red colour, variegated with yellow and white; and when recently powdered, appears yellow; but on being kept, becomes gradually redder. The second is the most valuable, and is brought to us from Turkey and Russia, in roundish pieces, with a large hole through the middle of each; it is more soft and friable than the former sort, and exhibits, when broken, many streaks of a bright red colour. This sort, unless kept very dry, is apt to grow mouldy and worm-eaten; the other is less subject to these inconveniences. Some of the more industrious artists are said to fill up the worm-holes with certain mixtures, and to colour the outside of the damaged pieces with powder of the finer sorts of rhubarb, and sometimes with cheaper materials. The marks of the goodness of rhubarb are, the liveliness of its colour when cut, its being firm and solid, but not stinty or hard; its being easily pulverable, and appearing, when powdered, of a fine bright yellow colour; its imparting to the spittle, on being chewed, a deep saffron tinge, and not proving slimy or mucilaginous in the mouth. Its taste is subacid, bitterish, and somewhat styptic; the smell is slightly aromatic.

## RHUBARB.

Turkey rhubarb is generally preferred to the East India sort, though the latter is more astringent, but has something less of an aromatic flavour. Tinctures made from both, with equal quantities of rectified spirit, have nearly the same taste; on drawing off the menstrua, the extract left by the tincture of the East India rhubarb proves in taste considerably stronger than the other. They seem both, says Dr. Lewis, to be the produce of the same climate, and roots of the same species of plant, taken up probably at different seasons, or cured in a different manner. Lewis's Mat. Med.

The Russian rhubarb and Turkey rhubarb, sometimes distinguished in the shops, seem to be the root of the same species of plant, grown in the same place, and prepared in the same manner; but Mr. A. T. Thomson (Lond. Disp.) inclines to believe, that the East Indian is the root of a different species, very probably of the "undulatum;" and the mode of preparation appears to be evidently different, from the aspect of the pieces.

Good Russian or Turkey rhubarb, says Mr. Thomson, has a peculiar, somewhat aromatic odour, and a bitter, slightly astringent, subacid taste; feels gritty between the teeth when chewed, and tinges the saliva of a bright yellow colour. It breaks with a rough hackly fracture, is easily pulverized, and affords a powder of a bright buff yellow colour. Water at 212° takes up 24 parts in 60; the infusion is of a brown colour, nearly clear, and reddens litmus paper. Alcohol extracts 2.7 from 10 parts, and gives a tincture of a rich golden colour, which reddens tincture of litmus; is not altered in its transparency by the addition of water; and

strikes a blackish olive hue with solution of sulphate of iron, but no immediate precipitate falls. Sulphuric ether takes up 1.5 in 10 parts of this rhubarb; the tincture is of a golden yellow hue, and when evaporated on water, leaves a thin pellicle of yellow resin, and abundance of extractive dissolved in the water, combined, however, with tannin. East Indian or Chinese rhubarb has a stronger odour, and is more nauseous to the taste than the Turkey; breaks with a more compact and smoother fracture; and affords a powder of a redder shade. Water takes up 30 parts in 60; the infusion is not so deep coloured as that of Russian rhubarb, more turbid, and reddens also litmus paper. Alcohol extracts 4 parts in 10; the tincture is of a much deeper colour, and brownish; gives a deeper red to litmus tincture; is rendered slightly turbid by the addition of water; and strikes a green, not black, olive with sulphate of iron, which it also quickly and copiously precipitates. Ether takes up 2 parts in 10; the tincture is deeper coloured, and when evaporated on water, affords the same results as the former kind, except that the compound of tannin and extractive is more soluble.

The infusion of Chinese rhubarb is more copiously precipitated by solution of isinglass than that of the Russian. Infusion of yellow cinchona throws down a copious greenish precipitate from infusion of Russian rhubarb, and a less copious, but more dense, bright yellow precipitate from that of Chinese rhubarb.

The following tables shew the effects of re-agents on the aqueous infusion of the two varieties of rhubarb.

TABLE I.—Precipitates formed by Acids, Alkalies, and Neutral Salts.

Variety of Rhubarb.	Sulphuric Acid.	Nitric Acid.	Muriatic Acid.	Oxymuriatic Acid.	Solution of Potash.	Solution of Subcarbonate of Potash.	Lime Water.	Muriate of Barytes.	Silicated Potash.
Russian.	copious, greenish-yellow.	scanty, flocculent, pale yellow.	scanty, very slowly formed, yellow.	slowly formed, pale olive.	none, but strikes a deep lake colour.	none, but strikes a reddish-brown.	scanty, slowly formed, brown.	scanty, olive-green.	none, but strikes a deep brown.
Chinese.	more copious, brownish-yellow.	less scanty, pale yellow.	scanty, quickly formed, brownish-yellow.	slowly formed, orange-yellow.	none, a deeper lake.	none, but renders it turbid, and deep reddish-brown.	copious, quickly formed, brown.	less scanty, orange-yellow.	none, but strikes a deep brown.

TABLE II.—Precipitates formed by Solutions of Metallic Salts.

Variety of Rhubarb.	Solution of Oxysulphate of Iron.	Solution of Nitrate of Silver.	Solution of Nitrate of Mercury.	Solution of Nitrate of Lead.	Solution of Muriate of Mercury.	Solution of Acetate of Lead.	Solution of Tartarized Antimony.
Russian.	copious, nearly black.	scanty, pale greenish-yellow.	copious, olive-yellow.	scanty, slowly formed, yellow.	scanty, slowly formed, pale olive.	scanty, greenish-yellow.	scanty, slowly formed, whitish.
Chinese.	copious, deep olive-green.	copious, orange-yellow.	copious, heavy, bright yellow.	scanty, slowly formed, deeper yellow.	copious, quickly formed, heavy yellow.	copious, yellow.	scanty, still more slowly formed.

## RHUBARB.

When the residue, after the action of water, is digested in muriatic acid, and solution of ammonia added in excess, the liquid becomes milky, and deposits oxalate of lime. What remains consists of woody matter, a small portion of alumen, and filix. Of the specimens which we examined, one drachm of the Russian rhubarb yielded twenty-six grains of the oxalate, while the same weight of East Indian yielded only eighteen grains.

From the results of the above experiments, rhubarb appears to contain a large portion of extractive matter, a small portion of resin, mucus, tannin, gallic acid, a colouring matter, oxalate of lime, and minute proportions of alumen and filix. They shew that the two varieties differ from each other in several respects. The Russian contains more tannin, oxalate of lime, and resin; the Chinese more extractive and gallic acid. But the purgative principle is still unascertained, although it appears to be combined with the extractive, and hence is soluble in water.

The yellow colour of rhubarb, it is said, is much less destructible than many other vegetable yellows. Aqua fortis, and other acids which destroy the colour of saffron, turmeric, &c. make no change in that of rhubarb, or at most render it only turbid. Volatile spirits heighten the colour, and incline it to red. Fixed alkaline salts have this effect in a greater degree. Mr. Model affirms that a considerable quantity of selenites is contained in rhubarb. In one experiment he obtained six ounces of selenites from four pounds of rhubarb; and in the other, no less than an ounce of selenites from two ounces and five drachms of old rhubarb. *Rozier's Journal* for July, 1775.

Rhubarb is a mild cathartic, and commonly considered as one of the safest and most innocent of the substances of this class. Besides its purgative virtue, it has a mild astringent one, discoverable by the taste, and by its striking an inky blackness with chalybeate solutions: hence it is found to strengthen the tone of the stomach and intestines, to leave the belly costive, and to be one of the most useful purgatives in diarrhœas, dysenteries, and all disorders proceeding from a debility and laxity of the fibres: it is frequently given with a view to this stomachic and corroborating virtue, rather than to its producing any considerable evacuations. It tinges the urine of a high yellow colour. Rhubarb in substance purges more effectually than any preparation of it: the dose is from a scruple to a drachm. From ʒj to ʒss of the powdered root opens the bowels freely; and from grs. vi to grs. x may be given for a dose, when its stomachic properties only are required. By roasting it with a gentle heat, till it becomes easily friable, its cathartic power is diminished, and its astringency supposed to be increased. The purgative virtue of rhubarb is extracted more perfectly by water than by rectified spirit; the root remaining after the action of water is almost, if not wholly, inactive; whereas, after repeated digestion in spirit, it proves still very considerably purgative: when the rhubarb has given out to spirit all that this menstruum can extract, it still imparts a deep colour, as well as a purgative impregnation, to water. A drachm of the extract, formed by inspissating the watery infusion, is not more efficacious than a scruple of the root in substance; but half a drachm of the extract, formed from the spirituous tincture, proves moderately purgative, though scarcely more so than an equal quantity of the powder. The spirituous extract dissolves almost wholly in water; and hence the tincture, like the spirituous infusions of most other vegetables, does not turn milky on being mixed with aqueous liquors: of the watery extracts scarce above one-fourth is dissolved by rectified spirit, and the part

that does not dissolve proves more purgative than that which does. Hence it appears, that rhubarb contains much more gummy or mucilaginous than resinous matter; and its purgative quality seems to reside chiefly in a combination of gummy and saline matter.

"The qualities of this root," says Dr. Cullen (*Mat. Med.* vol. ii.), "are that of a gentle purgative, and so gentle that it is often inconvenient by reason of the bulk of the dose required, which in adults must be from half a drachm to a drachm. When given in a large dose, it will occasion some griping, as other purgatives do; but it is hardly ever heating to the system, or shews the other effects of the more drastic purgatives. The purgative quality is accompanied with a bitterness, which is often useful in restoring the tone of the stomach, when it has been lost; and for the most part, its bitterness makes it fit better on the stomach than many other purgatives do. Its operation joins well with that of neutral laxatives; and both together operate in a lesser dose than either of them would do singly.

"Some degree of stipticity is always evident in this medicine; and as this quality acts when that of the purgative has ceased, so in cases of diarrhœa, when any evacuation is proper, rhubarb has been considered as the most proper means to be employed. I must, however, remark here, that in many cases of diarrhœa, no further evacuation than what is occasioned by the disease is necessary or proper. The use of rhubarb in substance for keeping the belly regular, for which it is frequently employed, is by no means proper, as the astringent quality is ready to undo what the purgative had done; but I have found that the purpose mentioned may be obtained by it, if the rhubarb is chewed in the mouth, and no more is swallowed than what the saliva has dissolved. And I must remark, in this way employed it is very useful to dyspeptic persons. Analogous to this is the use of rhubarb in a solution, in which it appears to me that the astringent quality is not so largely extracted as to operate so powerfully, as when the rhubarb was employed in substance."

The operation of rhubarb is quickened by the addition of neutral salts and calomel, the purgative powers of which it also reciprocally augments; so that a compound, formed of small portions of rhubarb and a neutral salt or calomel, acts with more certainty, and quicker, than large doses of either separately taken. Rhubarb is particularly adapted for the greater number of cases of diarrhœa, as it evacuates any acrid matter that may be offending the bowels, before it acts as an astringent. As a stomachic and astringent, it is usefully given in dyspepsia, hypochondriasis, and in a weakened relaxed state of the bowels, combined with ginger, nutmeg, soda, or bitters. Externally its powder is sometimes sprinkled over ulcers, to assist their granulation and healing.

Its officinal preparations are as follow: *viz.* *Infusum rhei*, Lond. Pharm., infusion of rhubarb, prepared by macerating for two hours a drachm of rhubarb root, sliced, with half a pint of boiling water, in a lightly covered vessel, and straining it.

*Infusum rhei palmati*, Edinb. Pharm., infusion of rhubarb, prepared by macerating half an ounce of bruised rhubarb root with eight ounces of boiling water, in a covered vessel, for twelve hours, and then adding one ounce of spirit of cinnamon, and straining it. These infusions differ chiefly in their strength; but that of the Edinburgh dispensatory is rendered pleasanter by the addition of the spirit. The colour of both is a reddish-brown, much deepened by the addition of alkalies. The following substances either occasion precipitation,

## RHUBARB.

precipitation, or alter the properties of this infusion, and are therefore incompatible in formulæ with it: *viz.* the strong acids and lime-water, solution of fulphate of iron, fulphate of zinc, nitrate of silver, oxymuriate of mercury, superacetate of lead, and tartarized antimony; infusions of catechu, cinchona, and cusparia.

These infusions are the best form in which rhubarb can be given, when they are intended for acting on the bowels. The dose of the former may be from  $f\text{ʒ}j$  to  $f\text{ʒ}iv$ , and of the latter half the quantity, united with neutral salts or aromatics, as circumstances may direct.

*Extractum rhei*, Lond. Pharm., extract of rhubarb, is obtained by macerating for four days, in a gentle heat, a pound of bruised rhubarb root, with a pint of proof spirit, and seven pints of water; then straining the solution, and setting it apart that the feculencies may subside. Pour off the clear liquor, and evaporate it to a proper consistence. The virtues of rhubarb are impaired during this process of inspissation, and the simple infusion is preferable. The dose is from grs. x to ʒʒ, given in the form of pills, or dissolved in peppermint water.

*Tinctura rhei*, Lond., tincture of rhubarb, is prepared by macerating for fourteen days two ounces of rhubarb root sliced, half an ounce of cardamom seeds bruised, two drachms of saffron, in two pints of proof spirit, and filtering. The Dublin pharmacopeia directs to take of rhubarb root sliced, two ounces; lesser cardamom seeds husked and bruised, and liquorice bruised, of each half an ounce; saffron, two drachms; and proof spirit, two pints: to digest for seven days, and then filter.

*Tincture rhei palmati*, Edinb., tincture of rhubarb, is prepared by digesting for seven days three ounces of rhubarb root sliced, half an ounce of lesser cardamom seeds bruised, in two pounds and a half of proof spirit, and filtering through paper.

*Tinctura rhei composita*, Lond., compound tincture of rhubarb, is prepared by macerating for fourteen days two ounces of rhubarb root sliced, half an ounce of liquorice root bruised, ginger root sliced, and saffron, of each two drachms, in a pint of water, and twelve fluid ounces of proof spirit, and then filtering.

*Tinctura rhei et aloes*, tincture of rhubarb and aloes, formerly *elixir sacrum*, or sacred elixir, Edinb., is prepared by digesting for seven days ten drachms of rhubarb root sliced, six drachms of soccotorine aloes powdered, half an ounce of lesser cardamom seeds bruised, in two pounds and a half of proof spirit, and filtering through paper.

*Tinctura rhei et gentiana*, tincture of rhubarb and gentian, Edinb., formerly *tinctura rhei amara*, or bitter tincture of rhubarb, is obtained by digesting for seven days two ounces of rhubarb root sliced, half an ounce of gentian root sliced, in two pounds and a half of proof spirit, and filtering through paper.

All these tinctures of rhubarb are purgative and stomachic; but they are not generally used in the first intention, on account of the strength of the menitruum, and are therefore more usually employed as adjuncts to saline purgatives, for giving them warmth, and to stomachic infusions in dyspepsia, flatulent colic, diarrhœa, the colliveness of old people, and of cold phlegmatic habits. The dose for operating as a purgative is  $f\text{ʒ}vj$ , and from  $f\text{ʒ}j$  to  $f\text{ʒ}iij$  for producing their stomachic effects.

*Pilule rhei compositæ*, Edinb., compound rhubarb pills. See PILLS.

*Vinum rhei palmati*, Edinb., wine of rhubarb, is prepared by macerating for seven days two ounces of rhubarb root sliced, a drachm of canella bark bruised, in two ounces of

proof spirit, and fifteen ounces of Spanish white wine, and filtering through paper. This wine, when newly prepared, has the same properties, and may be applied to the same uses, as the tincture; but it is liable to undergo decomposition. The dose is from  $f\text{ʒ}ʒ$  to  $f\text{ʒ}j$ , or more. Rhubarb is also an ingredient in a variety of compositions. Woodv. Med. Bot. Thomson's Lond. Disp.

The Indian rhubarb grown in our gardens has this peculiar property, that it yields a fine and clear gum. This is perfectly white and pellucid, and in the months of June and July is so plentiful, that an ounce may sometimes be gathered at a time from one plant of it. It exudates of itself from all parts of the stalks and ribs of the leaves, and sometimes from the under part of the leaves themselves. It stands in some places in large drops, and in others the stalks, &c. seem only to be covered with a thin layer of it; and the under part of the leaves in some have it in form of twisted wires or long icicles. The plant may always be seen wounded by a sort of caustic in the places where the germen makes its way out, and these may be followed with any pointed instrument through the skin. In some parts of the plant this juice is found to be turned gummy within it, and looks like clear ice. As this is the only known herbaceous plant that yields a true gum like that of trees, it would be worthy of observation, whether or not some of our own plants have some tendency of nature to form a juice of the same kind. It would be most proper to look for this in the plants of the same genus, and as nearly related to the rhubarb as we can. The docks, so common about our fields, are of the same genus; and the forrel shews, by its taste, that it is particularly allied to the plant; for both are alike of the dock kind, and both alike sour. It would be proper to look carefully about the leaves of forrel a little before it flowers, to see whether any thing like the same gum appears on it.

There is yet this farther analogy between this rhubarb and our common forrel; that the hulks of our forrel, boiled in water, with a little alum, turn it to a fine red colour; and the hulks of rhubarb do the same, and both the one and the other often turn red in decaying.

The juice of the roots of this rhubarb, extracted by bruising and steeping it in common water, when the liquor is strained and evaporated, becomes only a clear uninflam- mable gum, and melts in the flame of a candle. This gum, as well as that of the stalks and leaves, is of an insipid taste; and it is observable, that though the plant naturally yields it in so large a quantity, yet it will not flow from wounds made by art in any part of the plant. Upon the consideration of the insipid taste of this gum, and its solubility in water, we may found some probable conjecture, in regard to the different virtues of this plant in purging and binding.

The woody fibres have a strong taste; and, in all probability, are alone endued with the astringent quality. An infusion of rhubarb is said to purge, and a powder of it to bind: the reason is easily seen on this consideration. The water in infusion takes up all this gummy juice, and its other juices, but leaves the fibrose part behind, in consequence of which, it ought to purge without binding; but in case of giving the powder, the juices are in great part evaporated in the drying, and the woody part left almost alone; it therefore purges but little, and proves powerfully astringent. Phil. Trans. N<sup>o</sup> 224.

RHUBARB, in Agriculture, a plant of the thick, fleshy, tap-rooted, perennial kind, that may in some cases be probably cultivated in the field with advantage. There are two sorts, the *common*, and the *palmated* or *truc* kind. In the first the root strikes to a great depth, and is thick and branching,

having

having roundish smooth heart-shaped leaves, and an upright strong stem, three feet in height; while, in the latter, the root is thick and fleshy, and the leaves large and palmated, having the stem five, six, or more feet in height. Besides the use of the roots as a drug, parts of the young stalks of the plants, as well as of the leaves, may be made use of, when cut, peeled, and prepared in the spring season, as an article of food.

This plant is usually raised by sowing the well ripened seed in the autumn or early spring seasons, as about September, or in February, on beds of rich, deep, well-manured earth, either in the drill or broadcast manner: the plants being afterwards kept clean from weeds, and properly thinned. But the autumn is said to be the better, as the plants are more strong for planting in the spring. When the plants have attained four or five inches in growth, they should be planted out on hills, made at the distance of four feet, by digging out the earth to the depth of three feet, and filling in with well-rotten manure, and the mould taken out, so as to raise the plants a little above the natural surface of the land. Some, however, direct that a deep, rich, well prepared soil, that is neither too moist nor too dry, should be chosen for this sort of culture, the seeds being sown upon it in the early autumn, so as to remain without transplanting, as by this means the plants suffer no check in their growth, and the roots become larger and more fair. The plants, in both modes, must be constantly kept clean and free from all sorts of weeds, and in the latter they should be set out in the different hoeings to the distance of six or eight inches at first, and afterwards to two or three feet, or more. When the leaves and stems decay in the autumn, the ground should be well cleaned; and in the spring, on the plants protruding, be dug well, or hoed between them. In the third year the roots will, in most cases, be in a state to be taken up for use.

Another method has been suggested for raising these plants, as being more easy, secure, and expeditious, which is by planting the off-sets, eyes, or buds, separated from the upper parts of the roots, with a small proportion of the old root, having some root fibres to them; these may be taken from the old roots of three or four years' growth. In this way a year is saved, and the plants less exposed to danger from slugs, as well as more certain in growing, less tender, and the size of the roots equal. In Mr. Hayward's practice in this mode, the off-sets were slipped from the heads of large plants in the spring, and set, by means of a dibble, at the distance of about a foot. And on further experience, when he took up his roots in the spring or autumn, he divided the head into many parts, which he planted directly at two feet distance, where intended for further removal, but if to remain for a crop, at four feet and a half.

It may be noticed, that in the culture of this root, a gentle declivity is the best situation; it should not be too much shaded, either on the south or west. But it is essential that there be a great depth and richness of soil, which is best when of the light loamy kind, and perfectly free from any stagnation of moisture. Where the situation is flat, the land is best raised into ridges or beds, with deep furrows or trenches between them.

And when the seed-stems are removed in the autumn, the crowns of the plants should be well covered over with mould, so as to form a sort of hillock, as by this means the moisture will be more effectually kept from the plants.

But where the transplanting method is practised, it is advised that great care should be taken that the nursery beds are well watered, and protected from insects, as the stronger the plants are here, the better they succeed afterwards. In

forming plantations, and filling up vacancies in them, the finest and most healthy plants are always to be made use of. Where the chief bud is destroyed, they never answer well.

The particular injuries to which these young plants are exposed, are the attacks of slugs and insects, and too much exposure to frost in their more early growth; but afterwards they are sufficiently hardy.

In general the roots are proper for being taken up about the third or fourth year, or as soon as the plants have flowered perfectly. And the autumn is the best season for the purpose, when the stems decay, when they should be well dried, cleaned, and cut into thin pieces, stringing them upon packthread, and hanging them up to dry in a gradual manner.

It has been observed by the writer of the Perthshire Agricultural Report, that it is surprising the culture of rhubarb has not claimed more attention, and been adopted on a more extensive scale, as it is calculated to bring large profits.

The palmated rhubarb has been cultivated in Suffex by the earl of Egremont, for medicinal purposes, who has it dried and cured in as good order and preservation as any imported from abroad. It is taken out of the ground in autumn, after standing seven or eight years, and then washed clean, and dried, either in the sun, or on the flue of a hot-house, after being cut into thin pieces. In using it, no difference is found between it and the foreign, and great saving might be made in this way in the importation of the article.

RHUBARB, *Monk's*, is a species of dock. See RUMEX.

The root of this plant is more astringent than rhubarb, but is much inferior in its purgative virtue, though given, as usually directed, in double its dose; nauseating the stomach, without producing any considerable evacuation. It communicates a deep yellow tincture, both to water and spirit. Lewis.

RHUBARB, *White*. See METCHOCAN.

RHUBRA, in *Ancient Geography*, a town situated on the southern coast of the island of Corsica, between the port of Syracuse and the promontory Granicum. Ptolemy.

RHUBRICATA, a town of Hispania, in the Tarragonese, in the country of the Lacetanians. Ptolemy.

RHUBUNA, a town of Africa, on the northern bank of the river Gira, between Artagira and Lynxama. Ptolemy.

RHUDA, a town of Asia, in Parthia, between Pafcarta and Simpsimida. Ptolemy.

RHUDDLAN, or RHYDDLAN, in *Geography*, a borough town in the cwmwd of Rhuddlan, cantref of Tegeing (now called the hundred of Rhuddlan), county of Flint, North Wales, is situated on the eastern bank of the river Clwyd, at the distance of five miles N. from the city of St. Asaph, and 215 miles N.W. from London. It is a town of great antiquity, and, as appears from tradition, and likewise from the remains of its castle, was a place of considerable importance in early times. A large common in the immediate vicinity was the theatre of a dreadful battle fought between the Welsh, under prince Caradoc, and the Saxons, commanded by Offa, king of Mercia. In this action the Welsh were defeated, and their leader slain; and to add to their misfortunes, Offa put to death all the men and children who fell into his hands, but spared the women. The memory of the above tragical occurrence is commemorated in a ballad called "Morfa Rhuddlan," the air of which is characterized by Pennant as being "most tenderly plaintive." This town was constituted a free borough by king

Edward I., who held a parliament here in 1284, when the statute of Rhuddlan was passed. At a private house is still shewn a "Gothic window," which is said to have been part of the building used on the occasion of these parliamentary meetings. Another house is also pointed out as having been honoured by the residence of the monarch himself during his stay at Rhuddlan, but it is more likely that he occupied the castle; and certain it is, that queen Eleanor's accouchment of a daughter occurred there in 1283. A copy of the roll of the king's expences, while at Rhuddlan, is printed in the *Archæologia*, and exhibits several interesting and curious particulars relative to the prices of provisions and labour at that early period. Rhuddlan castle is built of a reddish free-stone, and is nearly square in form. At two of the opposing corners were formerly two towers, though the other corners had only one each. Of these, the three on the north-west side of the fortrefs are tolerably entire, but the remainder is much dilapidated. By whom this castle was originally built is uncertain; some writers attributing it to Llewelin-ap-Sityllt, about the commencement of the 11th century, and others to Robert de Rodelent, who lived towards the close of the same century. Be this as it may, however, it was destroyed by Gruffydd-ap-Crinan in the reign of Henry II., and was subsequently re-erected and fortified by that monarch. In 1399 it was seized and garrisoned by the earl of Northumberland, previous to the deposition of the unfortunate king Richard II., who dined here on his way to Flint castle. During the civil wars between king Charles I. and his parliament, Rhuddlan castle was at first occupied by the royalists, but, after a short siege, the garrison were forced to surrender to the parliamentary troops, commanded by general Mytton. This event happened in July 1646, and in the following December, the fortrefs was dismantled by order of parliament. It was surrounded by a deep ditch, and had an additional one on the north side: both of these ditches are still remaining. The walls are very strong, and well calculated for defence. South from the castle is a fortification, commonly supposed to have been constructed by the parliamentary troops as a battery during the siege above-mentioned; but though it may have been used for that purpose, it is doubtless of much higher antiquity. Near this spot formerly stood a house of Black friars, which must have been founded previous to 1268, as it is recorded, that in that year, Anian de Schonau, one of its priors, was made bishop of St. Asaph. It suffered greatly in the wars between king Edward I., and prince Llewelin ab Gruffydd; but it recovered and subsisted till the reign of Henry VIII. when it was dissolved, and its buildings granted to Henry ap Harry. Tanner states that there was another religious house in the immediate vicinity of Rhuddlan, as old as the year 1281, but no traces of its site can now be discovered.

Edward I., in his charter constituting Rhuddlan a borough, appointed the constable of the castle mayor, and ordered that two bailiffs should be chosen annually, as his assistants, from among the burgesses. Since the time of Oliver Cromwell, there having been no constable, there has consequently been no mayor, so that the bailiffs are now the chief officers of the town. The burgesses contribute towards the new election of a representative in parliament for the borough of Flint. The voters must either inhabit the town itself, or that part of the parish called Rhuddlan Franchise, which extends to the distance of a mile. At present no regular market is held here, but there are fairs for cattle on the 2d of February, 25th of March, and the 8th of September. The parish, according to the par-

liamentary returns of 1811, contains 131 houses, and 831 inhabitants.

The river Clwyd, upon which Rhuddlan is situated, is only navigable for vessels of about twenty tons burden as high up as the town; but about two miles below it is a port, into which vessels of considerable magnitude can enter and remain with security. Carlisle's *Topographical Dictionary of Wales*, 4to. 1813. Pennant's *Tour in Wales*, 1770, Lond. 2 vols. 4to. 1778.

RHUDEN, or RUTHEN, a town of Germany, in the duchy of Westphalia; 64 miles E. of Dusseldorp.

RHUDIANA, in *Ancient Geography*, a country of Asia, in Carmania. Ptolemy.

RHULA, in *Geography*, a town of Saxony, in the principality of Eisenach, famous for its manufacture of knives; four miles S.S.E. of Eisenach.

RHUMB, RUMB, or *Rum*, in *Navigation*, a vertical circle of any given place; or the intersection of a part of such a circle with the horizon.

Rhumbs, therefore, coincide with *points of the world*, or of the horizon.

And hence the mariners distinguish the rhumbs by the same names as the points and winds. But we may observe, that the rhumbs are denominated from the points of the compass in a different manner from the winds: thus, at sea, the north-east wind is that which blows from the north-east point of the horizon towards the ship in which we are; but we are said to sail upon the north-east rhumb, when we go towards the north-east.

They usually reckon 32 rhumbs, which are represented by the 32 lines in the rose, or card, of the compass.

Aubin defines a rhumb to be a line on the terrestrial globe, sea-compass, or sea-chart, representing one of the 32 winds which serve to conduct a vessel. So that the rhumb a vessel pursues is conceived as its route, or course.

Rhumbs are divided and subdivided like points. Thus, the whole rhumb answers to the cardinal point. The half rhumb to a collateral point, or makes an angle of  $45^{\circ}$  with the former. The quarter rhumb makes an angle of  $22^{\circ} 30'$  with it. And the half-quarter rhumb makes an angle of  $11^{\circ} 15'$ .

Sometimes navigators divide the 32 points into four quarters, and call the rhumb next the east the first rhumb, the next to that the second rhumb, &c.

For a table of the rhumbs, or points, and their distances from the meridian, see WIND.

RHUMB-Line, *Loxodromia*, is a line prolonged from any point of the compass in a nautical chart, except the four cardinal points; or it is the line which a ship, keeping in the same collateral point, or rhumb, describes throughout its whole course. See LOXODROMY.

The great property of the rhumb-line, or loxodromia, and that from which some authors define it, is, that it cuts all the meridians under the same angle.

This angle is called the *angle of the rhumb*, or the loxodromic angle.

The angle which the rhumb-line makes with any parallel to the equator, is called the *complement of the rhumb*.

An idea of the origin and properties of the rhumb-line, the great foundation of navigation, may be conceived thus: a vessel beginning its course, the wind with which it is driven makes a certain angle with the meridian of the place; and as it is supposed, the vessel runs exactly in the direction of the wind, it makes the same angle with the meridian which the wind makes.

Supposing then the wind to continue the same, as each point

point or instant of the progress may be esteemed the beginning, the vessel always makes the same angle with the meridian of the place where it is each moment, or in each point of its course, which the wind makes.

Now a wind, *e. gr.* that is north-east, and which, of consequence, makes an angle of  $45^\circ$  with the meridian, is equally north-east, wherever it blows, and makes the same angle of  $45^\circ$  with all the meridians it meets. A vessel, therefore, driven by the same wind, always makes the same angle with all the meridians it meets with on the surface of the earth.

If the vessel sail north and south, it makes an angle infinitely acute with the meridian, *i. e.* it is parallel to it; or rather fails in it. If it run east and west, it cuts all the meridians at right angles.

In the first case, it describes a great circle; in the second, either a great circle, *viz.* the equator, or parallel to it. If its course be between the two, it does not then describe a circle; since a circle, drawn in such a manner, would cut all the meridians at unequal angles, which the vessel cannot do.

It describes, therefore, another curve, the essential property of which is, that it cuts all the meridians under the same angle. This curve is what we call the *loxodromic curve*, *rhumb-line*, or *loxodromy*.

It is a kind of spiral, which, like the logarithmic spiral, makes an infinity of circumvolutions without ever arriving at a certain point, to which it yet still tends, and towards which it approaches at every step.

This asymptotic point of the rhumb-line is the pole: at which, were it possible for it to arrive, it would find all the meridians conjoined, and be lost in them.

The course of a vessel then, except in the two first cases, is always a rhumb-line; which line is the hypotenuse of a right-angled-triangle, whose two other sides are the ship's way or distance run in longitude and latitude. Now, the latitude is usually had by observation, and the angle of the rhumb, with one or other of the two sides, by the compass. See LATITUDE, and COMPASS.

All, therefore, that is required by calculation in sailing, is the value of the length of the rhumb-line, or the distance run.

But as such curve line would prove very perplexing in the calculation, it was necessary to have the ship's way in a right line; which right line, however, must have the essential property of the curve line, *viz.* to cut all the meridians at right angles. See CHART.

If  $PA$ ,  $PF$ ,  $PG$ , &c. (*Plate II. Navigation, fig. 5.*) be supposed meridians,  $AI$  the equator, and  $EB$ ,  $KL$ ,  $MN$ , parallels;  $AO$  will represent a rhumb-line, which makes equal angles with the meridians, and consequently different from those made by a great circle, which cuts the meridians at unequal angles; whence it follows that the rhumb is not a great circle of the sphere. If a ship, therefore, be at first directed towards  $E$ , and constantly persist in the same rhumb, it will never arrive at the place  $E$ , but at the place  $O$ , which is farther from the equator  $AI$ .

Hence, as on the surface of a sphere the shortest way between  $A$  and  $O$  is an arc of a great circle between  $A$  and  $O$ ; the rhumb-line is not the shortest way, or least distance from one place to another.

*RHUMB-Lines, Use of the.* 1. If the meridians  $PA$ ,  $PB$ ,  $PC$ ,  $PD$ , &c. (*fig. 6.*) be not very far apart, the rhumb-line  $AIHG$  is divided by the equidistant parallels  $LE$ ,  $MF$ ,  $NG$ , &c. into equal parts.

Hence, 1. The parts of the rhumb  $AI$  and  $AG$  are as

the latitudes  $AL$  and  $AN$  of the places  $A$  and  $G$ . 2. Since the arcs  $AB$ ,  $IK$ ,  $HF$ , are equal in magnitude, and therefore unequal in number of degrees; the sum of the arcs, called the *latus mecodynamicum*, or *miles of longitude*, is not equal to the difference of longitude  $AD$  of the places  $A$  and  $G$ .

2. The length of the rhumb-line  $AG$  is to the change or difference of latitude  $GD$ , in the same ratio as the whole sine to the co-sine of the angle of the rhumb.

Hence, 1. The rhumb failed on being given, together with the difference or change of latitude, turned into miles, the length of the rhumb-line, or the distance from the place  $A$  to the place  $G$  upon the same rhumb, is had by the rule of three. 2. The rhumb being given, together with the quantity of the ship's way on the same rhumb, *i. e.* the length of the rhumb  $AG$ ; the difference of latitude  $GD$  is had, by the rule of three, in miles, to be converted into degrees of a great circle. 3. The difference of latitude  $GD$  being given in miles, as also the length of the rhumb-line  $AG$ , the angle of the rhumb, and consequently the rhumb failed on, is had by the rule of three. 4. Since the co-sine of an angle is to the whole sine, as the whole sine to the secant of the same angle; the difference of latitude  $GD$  is to the length of the rhumb-line  $AG$ , as the whole sine to the secant of the angle of the rhumb.

3. The length of the rhumb-line, or of the ship's way in the same rhumb,  $AG$ , is to the *latus mecodynamicum* or *mecodynamic side*  $AB + IK + HF$ , as the whole sine to the sine of the loxodromic angle  $GAP$ .

Hence, 1. The rhumb, or angle of the rhumb, being given; as also the ship's way in the same rhumb-line  $AG$ , the *mecodynamic side* is had, by the rule of three, in miles, *i. e.* in the same measure in which the length of the rhumb is given. 2. In like manner, the *mecodynamic side*  $AB + IK + HF$  being given, as also the rhumb-line or ship's way  $AG$ , the rhumb failed is found by the rule of three.

4. The change of latitude  $GD$  is to the *mecodynamic side*  $AB + IK + HF$ ; as the whole sine to the tangent of the loxodromic angle  $PAG$  or  $AIB$ .

Hence the rhumb or loxodromic angle  $PAG$ , and the change of latitude  $GD$  being given, the *mecodynamic side* is found by the rule of three.

5. The *mecodynamic side*  $AB + IK + HF$  is a mean proportional between the aggregate of the rhumb  $AG$ , and the change of latitude  $GD$ , and their difference.

Hence the change of latitude  $GD$ , and the rhumb-line  $AG$  being given in miles, the *mecodynamic side* is found in the same measure.

6. The *mecodynamic side*  $AB + IK + HF$  being given, to find the longitude  $AD$ .

Multiply the change or difference of latitude  $GD$  by six, which reduces it into parts of ten minutes each; divide the *mecodynamic side* by this product, and the quotient gives the miles of longitude, answering to the difference of latitude in ten minutes; reduce these miles of longitude in each parallel into differences of longitude from a loxodromic table, and the sum of these is the longitude required.

7. If a ship sail on a north or a south rhumb, it describes a meridian; if on an east or west rhumb, it describes either the equinoctial, or a parallel to it. *Wolfii Elem. Math. tom. iv. cap. 11.*

1. To find the rhumb between two places by calculation, or geometrically, we have two canons, or proportions: the first, as the radius is to the co-sine of the middle latitude, so is the difference of longitude to the whole departure from the meridian, in the course between the two places proposed.

The second, as the radius is to the half sum of the co-sines of both latitudes, or (rather for geometrical schemes) as the diameter is to the sum of the co-sines of both latitudes, so is the difference of longitude to the departure from the meridian. For the application of these principles, see *SAILING*.

RHUN, PULO, in *Geography*. See POOLARON.

RHUNE, a river which rises in the New Forest, and runs into the Seine; two miles N.W. of Nordheim.

RHUS, in *Botany*, an ancient name, *ῥοος*, or *ῥοῦς*, of the Greeks, generally supposed of doubtful etymology. De Theis deduces this, and many similar words, which have a reference to a red colour, from the Celtic *rhudd* or *rub*, red. Hence, according to him, we have not only *Rubia*, but *Rosa*. The fruit of the original *ῥοος* of Dioscorides, *Rhus Coriaria*, well justifies this explanation.—Linn. Gen. 146. Schreb. 197. Willd. Sp. Pl. v. 1. 1477. Mart. Mill. Dict. v. 4. Sm. Prodr. Fl. Græc Sibth. v. 1. 206. Pursh 204. Ait. Hort. Kew. v. 2. 161. Juss. 369. Lamarek Illustr. t. 207. Gærtn. t. 44.—Class and order, *Pentandria Trigynia*. Nat. Ord. *Dumosa?* Linn. *Terebin-taceæ*, Juss.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, in five deep, erect, permanent segments. *Cor.* Petals five, ovate, moderately spreading. *Stam.* Filaments five, very short; anthers small, shorter than the corolla. *Pist.* Germen superior, roundish, as large as the corolla; styles scarcely any; stigmas three, heart-shaped, small. *Peric.* Berry roundish, of one cell. *Seed* solitary, roundish, bony.

Obf. Some species have dioecious flowers.

Ess. Ch. Calyx in five deep segments. Petals five. Berry superior, with one seed.

An extensive shrubby or arborescent genus, whose species are found in North America, Japan, China, the Cape of Good Hope, and a few in the south of Europe. Their qualities are of a caustic nature, in certain instances highly virulent, whence some species have acquired the name of Poison-trees. Others are celebrated for producing valuable resins for varnish. Willdenow has collected together the characters of thirty-three species; but many of them he had not seen, particularly those found by Thunberg at the Cape. The genus is divided into three sections, by the structure of the leaves, of which we shall give a few examples. Pursh has two species not in Willdenow. Twenty-one are cultivated in the English gardens. *Aiton*.

Section 1. *Leaves pinnate*. Thirteen species, to which the two described by Pursh are to be added; see hereafter.

*R. Coriaria*. Elm-leaved Sumach. Linn. Sp. Pl. 379. Willd. n. 1. Ait. n. 1. Sm. Fl. Græc. Sibth. t. 290, unpublished. Woodv. Med. Bot. t. 261. Ger. Em. 1474. (*Rhus*; Matth. Valgr. v. 1. 195.)—Leaves pinnate; leaflets oval, bluntly ferrated, downy beneath; their common stalk winged in the upper part.—Native of the Levant. Frequent in our gardens and shrubberies, ever since the days of Gerard, (though less common than the American *R. typhinum*), flowering in July, and retaining its dense, branched, ample, upright clusters, of deep-red, rough, coriaceous berries, even till winter, after the leaves are fallen. The tree is of a dwarf bushy habit, with spreading, ascending, round, downy branches, of a soft spongy texture. *Leaves* from eight inches to a foot long, of about five pair of leaflets, with an odd one; paler, downy, and veiny beneath. *Flowers* greenish, each with a large hoary germen, which becomes a globular, crimson, hairy berry, the size of an Elder-berry. The taste of this fruit is very acid and astringent. It has

been used in Greece, from the most remote antiquity, for tanning leather; as have also the leaves, to the present day. Both have likewise been employed in medicine, either for their tonic or cooling qualities, nor do they appear to possess any of the dangerous qualities for which some species of this genus are remarkable. Dr. Woodville's figure of this plant ought to have been quoted in Hort. Kew. as not cited by Willdenow, and being moreover an English publication.

*R. javanicum*. Java Sumach. Linn. Sp. Pl. 380. Willd. n. 3. Ait. n. 3. Thunb. Jap. 121.—Leaves pinnate, ovate, pointed, ferrated; very downy and soft beneath.—Native of Japan, flowering in September. Introduced into the stoves at Kew, by sir Joseph Banks, in 1799. The branches, and all the stalks, as well as the backs of the leaves, are clothed with extremely soft, dense, velvet-like pubescence, as is the upper side of the foliage in some degree. Each leaf has three pair, with an odd one, of stalked, ovate, taper-pointed leaflets, strongly ferrated, and about an inch and a half long. *Flowers* very small, in long, slender, lax, simple, axillary clusters.

*R. glabrum*. Smooth Sumach. Linn. Sp. Pl. 380. Willd. n. 4. Ait. n. 4. Pursh n. 2. Kalm's Travels, v. 1. 66. 75. (*R. virginicum*, panicula sparsa, ramis patulis glabris; Dill. Elth. 323. t. 243. f. 314.)—Leaves numerously pinnate, lanceolate, ferrated, smooth on both sides; glaucous beneath.—Common in North America, flowering in July and August, nor is it rare in our shrubberies. Kalm says that neglected corn-fields are soon overrun with this tree, whose roots subsequently render ploughing the ground very difficult. The leaves consist of from eight to twelve pair of longish taper-pointed leaflets, smooth and naked on both sides. The fruit much resembles the first species in colour and mode of growth, but is less hispid. According to Mr. Pursh, the *R. elegans*, Ait. Hort. Kew. n. 5. Willd. n. 5, is only a variety of this, with dioecious flowers, and a more scarlet-coloured fruit.

*R. viridiflorum*. Green-flowered Sumach. Lamarek Dict. v. 7. 504. Pursh n. 3. (*R. canadense*; Mill. Dict. ed. 8. n. 5.)—Leaves numerously pinnate, ovato-lanceolate, ferrated; glaucous, and somewhat downy beneath. Clusters erect.—On the edges of woods in dry sunny situations, in Pennsylvania and Virginia, flowering in July and August. This is one of the species added by Mr. Pursh, after Poirer in Lamarek, but not without a doubt of its being distinct from the last. We can find no important difference in a specimen from the French gardens, except that the leaflets are rather more ovate. The flowers are yellowish-green. *Leaves* not always downy.

*R. pumilum*. Dwarf Poison Sumach. Michaux Boreal Amer. v. 1. 182. Pursh n. 4.—Leaves numerously pinnate, oval, scarcely pointed, deeply toothed; downy beneath. Branches and footstalks downy. Fruit clothed with velvet down.—Native of Upper Carolina, flowering in July. The stem is not above a foot high. This species is unknown in our gardens. Mr. I. Lyon, who gathered it, assured Mr. Pursh, that it was the most poisonous of the genus, he having been "poisoned all over his body, and lamed for a considerable time," in consequence of collecting the seed.

*R. Verniv.* Varnish Sumach. Linn. Sp. Pl. 380. Willd. n. 6. Ait. n. 6. Pursh n. 5. Kalm's Travels, v. 1. 68. 77. (*Toxicodendron*, foliis alatis, fructu rhomboide; Dill. Elth. 390. t. 292. f. 377.)—Leaves pinnate, very smooth, as well as the branches; leaflets elliptical, entire, somewhat abrupt, pointed. Clusters compound, lax. Flowers dioecious. Fruit polished.—Found in low copses, from Canada to Carolina, flowering in July. *Pursh*. It has been in

our gardens for a century past, but is not common. Kalm speaks of its dangerous effects, to various persons, whose skin, and whole body, in some cases, are affected with inflammation, swelling and pain, in consequence of their touching any part of this tree, or exposing themselves to its effluvia; whilst others, even of the same family, can cut or handle it with impunity. Kalm himself was generally unhurt by this poison, but on one occasion he did not entirely escape its effects. The whole tree is very smooth. *Leaflets* about six pair with an odd one. *Berries* the size of a pea, white and remarkably polished, both in a fresh and dry state. Miller contended that this was the same with the true Varnish-tree of Japan, described in Kämpfer's Am. Exot. 791. t. 792; which opinion was combated by Ellis, in the Philosophical Transactions, n. 112. We believe the latter to be in the right. The two trees, indeed, seem very nearly akin, but the *leaflets* in Kämpfer's plate are broader than those of the American plant, nor does his description of the fruit exactly answer. Yet Thunberg calls the Japanese plant *Rhus Vernix*. Nothing seems to be known in America, as to the tree in question affording any varnish, though that point is certainly worth enquiry, considering its near relationship, at least, to one whose produce is so valuable. Kämpfer speaks of the poisonous effects of the effluvia of his varnish-tree, like what we have related of the other.

Section 2. *Leaves ternate or quinate*. Eighteen species

*R. Toxicodendron*. Trailing Poison-oak, or Sumach. Linn. Sp. Pl. 381. Willd. n. 17. Ait. n. 11. Pursh n. 7. (*Edera trifolia canadensis*; Cornut. Canad. 96. t. 97. Barrel. Ic. t. 228.)  $\beta$ . *R. radicans*; Linn. Sp. Pl. 381. Willd. n. 16. Ait. n. 10. Kalm's Travels, v. 1. 67. 177. (*Toxicodendron triphyllum glabrum*; Duham. Arb. v. 2. 341. t. 98.)—Leaves ternate; leaflets stalked, ovate, angular, cut, or crenate. Stem creeping.—Common in woods, fields, and hedges, from Canada to Georgia, flowering in June and July. *Pursh*. We readily concur with Mr. Pursh, in considering these two Linnæan species as mere varieties. The *leaves* when young are more downy beneath, in some instances than in others; but that character, as well as their notches, is certainly variable. We speak with confidence on this subject, having been at no small trouble formerly, to determine which was the plant recommended in paralytic and rheumatic complaints, by some eminent physicians in England and France; and after much examination, finding no certain or permanent difference between the two. Kalm speaks of the poisonous qualities of the present species, as like those of *R. Vernix*; but it had no effect on him, even when he made the rash experiment of dropping the juice into his eye. The *stem* never grows erect, but when it meets with support, will climb, like ivy, to the tops of the loftiest trees. The *leaflets* are of a broad, ovate, or rhomboidal form, pointed, always more or less downy, at least about the ribs, and sometimes quite covered with soft down at the back; their margin occasionally almost entire, but most generally, in the downy variety, strongly crenate, cut, or lobed. *Flowers* in compound axillary clusters, greenish, dioecious. *Berries* white. Both varieties have long been known in our gardens, but have nothing to recommend them to general culture, even were they unexceptionable as to danger.

*R. tomentosum*. Woolly-leaved Cape Sumach. Linn. Sp. Pl. 382. Willd. n. 24. Ait. n. 15. (*Vitex trifolia minor indica ferrata*; Commel. Hort. v. 1. 179. t. 92.)—Leaves ternate; leaflets stalked, rhomboid, somewhat angular; white and very downy beneath.—Native of the Cape of Good Hope. It was introduced very early by the Dutch, into the European gardens, but we know not whether it has been preserved, or noticed, though an extremely handsome

evergreen shrub, the backs of whose *leaves* are elegantly white and downy, with reddish veins. We know nothing of the *flowers* or *fruit*. Commelin mistook this plant for the East Indian *Vitex trifolia*.

Several other three-leaved species of *Rhus*, from the Cape, elegant evergreen shining-leaved shrubs, are cultivated in our more curious collections, as may be seen in Aiton. We subjoin one species to this section, which Willdenow has not admitted here.

*R. pentaphyllum*. Five-leaved Morocco Sumach. Defout. Atlant. v. 1. 267. t. 77. (*Rhamnus pentaphyllum*; Jacq. Obf. fasc. 2. 17. Linn. Syst. Veg. ed. 14. 233. *R. ficulus*; Syst. Nat. ed. 12. v. 3. 229. *R. ficulus pentaphyllos*; Bocc. Sic. 43. t. 21.)—Leaves ternate or quinate; leaflets linear-lanceolate, dilated upwards, obtuse, nearly smooth; cut or undivided. Stem thorny.—Native of uncultivated hills in Morocco and Sicily. A thorny shrub, or small tree, with numerous, round, smooth, grey branches. *Leaves* alternate, stalked, digitate, of from three to five narrow-wedge-shaped, obtuse leaflets, above an inch long; somewhat downy when young; either quite entire, or unequally toothed, sometimes pinnatifid. *Flowers* pale yellow, in axillary compound clusters, dioecious. *Berry* red, resembling hawthorn, but with three tubercles at the top; its flavour slightly acid, not unpleasant. The *bark* is used for tanning, and for dyeing red. *Desfont*.

Section 3. *Leaves simple*. Two species.

*R. Cotinus*. Venice Sumach, or Coecygria. Linn. Sp. Pl. 383. Willd. n. 32. Ait. n. 21. Jacq. Austr. t. 210. Coggyria Theophrasti, and *Cotinus coriarius* Plinii; Ger. Em. 1476. *Cotinus*; Duham. Arb. v. 1. t. 78.)—Leaves simple, obovate, or orbicular.—Native of Austria, Switzerland, Italy, and Greece, in hilly situations. Common with us in plantations, for the sake of the very singular and ornamental appearance of its elongated feathery fruit-stalks. The *stem* is bushy, the height of a man. *Leaves* smooth, orbicular, entire. *Flowers* greenish, small, in terminal compound panicles. *Fruit* gibbous. The *leaves* and *stalks*, when bruised, have an aromatic but pungent and acid scent. The whole plant is used for tanning in Italy, and called *Scotins*; see Smith's Tour. The wood is much used by the modern Athenians, according to Dr. Sibthorp, for dyeing wool of a most beautiful and rich yellow.

*R. atrum*. Black Sumach. Forst. Prodr. 23. Willd. n. 33.—“Leaves simple, ovate-oblong. Flowers polygamous.”—Found by Forster in New Caledonia. A shrub or tree. We know nothing more of this species, the only one, except *Cotinus*, with simple leaves.

RHUS, in Gardening, contains plants of the tree and shrub kinds, sumach and toxicodendron; of which the species cultivated are, the elm-leaved sumach (*R. coriaria*); the stag's-horn Virginian sumach (*R. typhinum*); the scarlet sumach (*R. glabrum*); the Carolina sumach (*R. elegans*); the lentiscus-leaved sumach (*R. copallinum*); the Venice sumach (*R. cotinus*); the trailing poison-oak, or sumach (*R. toxicodendron*); the varnish sumach (*R. vernix*); the rooting poison-oak, or sumach (*R. radicans*); the woolly-leaved sumach (*R. tomentosum*); the narrow-leaved sumach (*R. angustifolium*); and the shining-leaved sumach (*R. lucidum*).

The branches in the first sort are used instead of oak bark for tanning leather, and it is said that Turkey leather is all tanned with this shrub.

In the third sort there are several varieties; as the New England sumach, in which the stem is stronger, and rises higher than that of the second sort; the branches spread more horizontally, they are not quite so downy, and the

down is of a brownish colour; the leaves are composed of many more pairs of leaflets, and are smooth on both sides: the flowers are disposed in loose panicles, and are of an herbaceous colour. The Canada smooth red sumach, which has smooth branches of a purple colour, covered with a grey pounce; the leaves are composed of seven or eight pairs of leaflets, which are four inches and a half long, and one inch broad in the middle, terminating in acute points, and a little serrate, of a lucid green on their upper surface, but hoary on their under, and smooth: panicle large, composed of several smaller, each on separate footstalks, the whole covered with a grey pounce; the flowers are of a deep red colour.

In the sixth sort the root is used for dyeing: the leaves and young branches dye black; and the bark is used for tanning leather.

In the eighth species Martyn says, that the milky juice stains linen a dark brown. The whole shrub is, in a high degree, poisonous; and the poison is communicated by touching or smelling any part of it.

The ninth species having, in common with ivy, the quality of not rising without the support of a wall, tree, or hedge, it is called in some parts of America creeping ivy. It will climb to the top of high trees in woods, the branches every where throwing out fibres that penetrate the trunk. When the stem is cut, it emits a pale brown sap of a disagreeable scent, and so sharp, that letters or marks made upon linen with it cannot be got out again, but grow blacker the more it is washed. Like rhus vernix it is poisonous to some persons, but in a less degree. Kalm relates, that of two sisters, one could manage the tree without being affected by its venom, whilst the other felt its exhalations as soon as she came within a yard of it, or even when she stood to leeward of it, at a greater distance; that it had not the least effect upon him, though he had made many experiments upon himself, and once the juice squirted into his eye; but that on another person's hand, which he had covered very thick with it, the skin, a few hours after, became as hard as a piece of tanned leather, and peeled off afterwards in scales.

There is a variety with a straight and stout trunk, having a brownish ash-coloured bark: the leaves smooth, veined, bright green above, somewhat paler underneath, pendulous, and somewhat bent back: in the male plant the leaves are rather wider and longer, and are drawn more to a point; in the female they are shorter and blunter, and the petioles are reddish, whereas in the others they are green: the flowers axillary, in racemes; the males larger, whitish-yellow; the females smaller, herbaceous, on the germ instead of the style there are two, sometimes three black dots: fruits round, the size and form of coriander seeds, streaked with five lines, remaining on the tree till new flowers come out; when the outer rind comes off, and a cretaceous substance comes into view, in which an ash-coloured, hard, horny seed is involved, slightly divided on the upper part, and somewhat kidney-shaped.

*Method of Culture.*—The first nine sorts of these plants are capable of being raised by seeds and layers, and some of them also by suckers, or their rooting branches. In the first method such of them as do not send up suckers should have the seed procured from abroad, and sown in pots of a large size, or in beds of light mould, being covered in about the depth of half an inch in the autumn. Those in pots should be protected from the frosts during the winter, and if plunged in a moderate hot-bed in the early spring, they will be rendered more forward, letting the plants have a free air when they appear. Those in the open ground often remain long before they vegetate; they should be kept free from

weeds, be well watered in summer, and have the protection of mats the first winter. When the plants have had the growth of a year or two, they may be planted out in nursery-rows till fit to be set out in the places where they are to remain. The potted plants should have the protection of the frame the second winter, air being freely admitted in mild weather; and in the spring following they may be shaken out of the pots without injuring the roots, and be set out in nursery-rows, three feet apart, and a foot distant in the rows, where they may remain two years, and then be planted out where they are to remain.

Such sorts as have young branches sufficiently low, may have them laid down in the slit method; when they will mostly have stricken root in the course of a year, and may be taken off and planted out where they are to remain, or in the nursery.

And all those sorts that send up suckers from the roots should have them taken up during the winter, and planted out in nursery rows, in the manner of the seedlings, till of a proper growth to be planted out.

The seventh and ninth sorts may likewise be increased by their trailing branches, which have stricken root as they rest on the ground, which should be taken up with their roots entire in the autumn, winter, or in early spring, and be planted out, either where they are to remain, or in nursery rows, till of sufficient growth for the purpose they are intended.

The first and fourth sorts, being the most tender, require the most sheltered situations.

Most of these plants afford a milky juice, which is extremely acrid and corrosive.

The three last sorts may be raised by cuttings and layers with great facility. In the first method, the cuttings of the young shoots should be planted out in pots of light fresh mould, in the spring and early summer months, plunging them in a moderate hot-bed, where they readily strike root, being occasionally watered and shaded: and when they have formed good roots, they may be potted off into separate pots. And in the latter mode, any of the young wood may be laid down in the usual manner, in the early spring, when by the autumn they will mostly have stricken good root, and may be taken off, and be potted out the same way as the cuttings.

All the first nine sorts have a fine effect in mixture with other deciduous shrubby plants, in the borders, clumps, and other parts of pleasure grounds, and the three last afford variety among other potted greenhouse plants of the less tender kinds.

*Rhus Cobbe*, in *Botany*. See SCHMIDELIA.

*Rhus*, in the *Materia Medica*. This genus comprehends a variety of species, which are known to be poisonous; but the *rhus coriaria*, or elm-leaved sumach, is perfectly innocent, and its leaves have been used occasionally for culinary purposes. Its medicinal qualities are owing to its stypticity or astringency, which property renders it useful in dyeing, and also in tanning of leather, to which purpose it was applied in the time of Dioscorides. The leaves and berries have been used in medicine; but the leaves are more astringent and tonic, and have been commonly employed in complaints which indicate remedies of this class. The berries, which are of a red and compressed figure, contain a pulpy matter, in which is lodged a brown, hard, oval seed, manifesting a considerable degree of astringency. The pulp, even when dry, is gratefully acid, and has been found to contain an essential salt similar to that of wood-forrel, or perhaps more nearly allied to crystals of tartar. An infusion of the dry fruit is not blackened by a solution of iron,

so that it appears to be destitute of astringency; but its acidity is very grateful, and hence the French have called it "le vinaigrier." Like many other acid fruits, these berries, which in eastern countries are used as a pickle, may be advantageously taken to allay febrile heat, and to correct bilious putrescency. The *rhus toxicodendron* and *radicans* have of late been recommended in paralytic affections; the latter by M. Frefnoi, and the former by Dr. Alderson of Hull: but the cases in which these virulent plants were employed are but few and indecisive. They excite, however, a sense of heat and pricking, and irregular twitches in the affected limbs. It is suggested that some advantage has been derived from their use in herpetic eruptions. The dose of the powdered leaves may be gr. ss, given twice or thrice a day, and gradually increased to grs. iv, in the form of a bolus. The stems of the toxicodendron, when cut or broken, exude a milky juice, which inflames the skin wherever it touches, and becomes black when it is exposed for a short time to the action of atmospheric air. This juice forms an indelible black stain on linen cloth, and is used in Japan, where it is a native, as a varnish. (Phil. Trans. vol. xlix. p. 158. See VARNISH.) The leaves are inodorous, and their taste is mawkish and subacid. Their virtues are completely extracted by water, and partially by alcohol. The aqueous infusion reddens litmus paper; precipitates the solution of iron black, that of nitrate of silver brown, and throws down a precipitate with gelatine. Hence it contains gallic acid and tannin; but its effects chiefly depend on a narcotic principle. Woodv. Med. Bot. Thomson's Lond. Disp. See SUMACH and TOXICODENDRON.

RHUSELNIUM, in *Botany*, a name given by some authors to the ranunculus.

RHUSTICANA, or RUSTICANA, in *Ancient Geography*, a town of Hispania, in the interior of Lusitania, between Talebriga and Medeculia. Ptolemy.

RHUSUNCORÆ, or RUSUCURRUM, a town of Africa, in Mauritania Cæsariensis. Ptolemy. It had the title of a Roman colony.

RHUTHYN, or RUTHIN, in *Geography*, a borough and market-town in the cwmwd of Llannerch, cantref of Dyffryn-Clwyd, (now called the hundred of Rhuthyn,) county of Denbigh, North Wales, is situated on the slope of a considerable hill, which rises near the centre of the delightful vale of the Clwyd, at the distance of 205 miles N.W. from London. This town, from the etymology of its name, appears to have derived its origin from a castle, called Rhyddin, or the red fortrefs, in allusion to the colour of the stone of which it is constructed. Although there was probably a walled fortrefs here anterior to the reign of king Edward I., yet the last castle erected here was most probably by this monarch. Camden, however, assigns its origin, as well as the town, to a baron named Roger Gray. Its history affords only a few events worthy of notice. In the year 1400 Owen Glyndwr attempted to take it by assault, but was unsuccessful; so that after pillaging the inhabitants, and setting fire to the town, he retreated precipitately to the mountains. In the reign of king Charles I. it was garrisoned in the royal cause, till about the middle of April, A.D. 1646, when it was compelled to surrender, after having sustained a siege of two months. Not long subsequent to that period, it was dismantled by order of parliament, and has since gradually fallen into its present ruinous state; only a few fragments of walls remaining to mark its site and character.

Rhuthyn is described as having been formerly a populous town, and as possessing the best market of any in the vale. This pre-eminence, however, is now lost; though it is yet

a respectable and flourishing place, containing, according to the parliamentary reports of 1811, 271 houses, and a population of 1292 persons. The government is vested in two aldermen and sixteen common council-men, chosen annually in the lord's court. The number of burgesses is unlimited. Rhuthyn is a borough both by prescription and by charter, and joins with Denbigh in returning a representative to the national senate. It has two markets, weekly; one on Saturday for provisions, and another on Monday for corn, &c.; besides which, there are six annual fairs. The lordship of Rhuthyn, a manorial right belonging to the Middleton family of Chirk-Castle, comprises three comots, viz. Coleigon, Dogfeilyn, and Llannerch; and is distinct with respect to government from the hundred, the lord appointing a steward to it. Here is a free-school of equal, if not greater, celebrity than any other in North Wales. It was founded and endowed by Gabriel Goodman, D.D., who was dean of Westminster in the reign of queen Elizabeth. His descendant, Godfrey Goodman, was likewise a benefactor to the town. From this school young men are sometimes admitted into orders, without having graduated at any university. It has two masterhips, the head one of which is in the gift of Jesus college, Oxford. The town-hall is situated near the market-place, and is fitted up with apartments for holding the hundred courts, the county assizes, and the quarter sessions; which last are held alternately here and at Denbigh. The new gaol is a handsome and commodious building, erected according to designs furnished by Mr. Joseph Turner. The debtors' apartments and those of the felons are divided by a lofty wall; and both have spacious yards, with baths, attached to them. The church is a large structure of considerable antiquity. It was originally conventual, having been attached to a religious house of the order of monks denominated Bonhommes. In the year 1310, however, it was made collegiate by John de Gray, who placed in it a chapter of seven regular canons, and conferred upon them considerable landed possessions, and numerous privileges. The apartments for the canons were connected with the church by a cloister, of which a portion is still remaining, converted into a residence for the warden of an hospital, which was founded and endowed by Gabriel Goodman, the founder of the free-school, as an asylum for twelve decayed housekeepers, viz. ten men and two women. The warden is *ex officio* rector of the parish of Rhuthyn, and has, besides, the government of the free-school. The interior of the church is much admired, and particularly its roof, which is a very curious piece of workmanship, consisting of small squares, adorned with various sculptures, and bearing the names of the different workmen employed in their formation. The collegiate establishment here was dissolved at the period of the general suppression, when its lands were granted to William Winlove and Richard Fyld. There are no remarkable monuments in this church, excepting that of Dr. Gabriel Goodman, which displays a bust of the deceased, in marble. The doctor was a native of Rhuthyn, where he was born in 1583. He was successively advanced to be canon of Windsor, dean of Rochester, and bishop of Gloucester. See Fuller's Church History, book xi. Worthies, and Chalmers's General Biographical Dictionary.

The vicinity of Rhuthyn presents some objects worthy of notice. At a short distance from the town is the neat village of Llanrhydd, which is noted for the fine sculptural monuments and decorations in its church. Near this village is the Bathafarn, anciently a feat belonging to the lord Gray; and more to the south-west lie Pool-Park and Bachymbyd, both seats of the lord Bagot. Stretching towards

wards the north is the vale of Clwyd, which is deservedly celebrated by all travellers. Commencing at Rhuthyn, it extends not less than twenty-four miles in length, and from six to eight in breadth, exhibiting a rich scene of cultivation, happily blended with many of those objects which constitute the picturesque. On a small eminence in this vale stands the village of Llan-Rhaeadar; and near it is a well, called Ffynnon Ddyfnog, which is much esteemed by the inhabitants for its medicinal quality in the cure of rheumatism. The church here is an elegant structure in the pointed style, and has a beautiful east window, ornamented with stained glass. The subject is the root of Jesse, who is represented as extended upon his back, with the genealogical tree issuing from his loins, comprising all the kings of Israel and Judah, down to the birth of Christ. Above is an outline rose, including an eye surrounded with a radiance, and another rose of Lancaster to correspond; which last emblem indicates that the work was executed after the accession of Henry VII. to the throne. Here is a splendid but tasteless monument to the memory of Maurice Jones, esq., who founded an alms-house in this parish, A.D. 1720; and in the church-yard is a striking instance of genealogical vanity, in an inscription to the memory of John ap Robert, whose pedigree is traced up to Cadel, king of Powis. Carlisle's Topographical Dictionary of Wales, 4to. 1813. A Tour in South Wales, by the Rev. W. Bingley, 8vo. 1801. Pennant's Tour through Wales, 1770, 2 vols. 4to.

RHYAS, from *ρῆναι*, to flow, in Surgery. See RHŒAS.

RHYDDA, in *Ancient Geography*, a town of Palestine, belonging to the Arabs, according to Josephus.

RHYME, RIME, *Ryme*, or *Rime*, in Poetry, the similitude of cadence and termination of two words which end two verses, &c.

Or, rhyme is a similitude of sound between the last syllable or syllables of one verse, and the last syllable or syllables of a verse succeeding either immediately, or at a distance of two or three lines.

Rhyme is a modern invention, and the product of a Gothic age; Milton calls it the *modern bondage*. Yet some authors will have it, that the English, French, &c. borrow their rhyme from the Greeks and Latins. The Greek orators, they say, who endeavoured to tickle the ears of the people, affected a certain cadence of periods, which ended alike, and called them *ομοιοπιδευστα*. The Latins, who imitated them, called these chining terminations, *similitudo d'sinentia*.

This affectation increased as the Latin tongue declined; so that in the later Latin writers, scarcely any thing is more common than rhyming periods.

The French, and from them the English, &c. adopted this cadence of rhyme, which seemed to them more pretty and agreeable than the metrical verses of the Greek and Roman poets.

This kind of Latin poetry in rhyme was much in vogue in the twelfth century; and the verses thus running were called Leonine verses, for what reason Camden owns he does not know (for a lion's tail, says he, does not answer to the middle parts, as these verses do); but, doubtless, they had their name from a French monk of St. Victor at Marzeilles, about the year 1135, called Leoninus, who first composed them with success, and of whom we have several pieces in them remaining, addressed to pope Adrian IV. and Alexander III. It is certain, however, (says Dr. T. Warton, Hist. of English Poetry, vol. i.) that rhymed Latin verses were in use at a much earlier period. Pelloutier (Mem. sur la Lang. Celt. part i. vol. i. ch. 12.) has given a very early specimen of Latin rhymes, occurring in

the beginning of the seventh century. Latin rhymes seem to have been first used in the church hymns, but Leonine verses are properly the Roman hexameters or pentameters rhymed, and it is not improbable, that they had their name from the above-mentioned monk, who was the most popular, and almost only Latin poet of his time in France. He wrote many Latin pieces not in rhyme, and in a good style of Latin versification. The early French troubadours mention a sort of rhyme in their vernacular poetry partly distinguished from the common species, which they call Leonine or Leonime.

Camden has given us a collection of Latin rhymes of our ancient English writers; among whom, Walter de Mapes, archdeacon of Oxford, in the time of king Henry II. makes a principal figure, especially for two pieces, the one in praise of wine beginning,

“ Mihi est propositum in taberna mori,  
Vinum sit appositum morientis ori;  
Ut dicant, cum venerint, angelorum chori,  
Deus sit propitius huic potatori.”

The other against the pope, for forbidding the clergy to have wives, beginning,

“ Prisciani regula penitus cassatur,  
Sacerdos per *hic* et *hæc* olim declinatur;  
Sed per *hic* solummodo nunc articulatur,  
Cum per nostrum præfulum *hæc* amoveatur.”

Since the restoration of learning in the sixteenth century, attempts have been made to banish rhyme out of the modern poetry, and to settle the English and French verses on the footing of the ancient Greek and Latin ones, by fixing the quantities of the syllables, and trusting wholly to those, and to the numbers or measure.

This Milton has done, with great success, in his Paradise Lost, and other pieces; and after him Philips, Addison, and some others. Verses of this kind we call *blank verses*. See VERSE.

The French have attempted the same, but not with the same success. Jodelet made the first essay, and after him Pasquier; but they both failed. Passerat and Rapin followed them, and failed, like them. Their hexameter and Sapphic verses were neither imitated nor approved; and the cadence of rhyme was generally preferred to quantity, or the use of long and short syllables. Des Portes, likewise, made some essays of verses, constructed of long and short lines, without rhyme, but the attempt only served to convince the world, that this kind of measure is inconsistent with the genius of the French tongue.

To succeed in such kind of verses, there must be a liberty of varying the order of the words, or of changing their situation, as may best suit the occasions of the poet; of making the substantive either go before or follow after the verb, as the verse requires, &c. Now none of the modern tongues will admit of such an arbitrary situation of the words, equally with the ancients; yet none will allow this more than the English, nor any less than the French.

The principal defect in rhyme is the full close which it forces upon the ear at the end of every couplet; and in this respect it is far inferior to *blank verse*; (which see.) Besides, the constraint and strict regularity of rhyme are unfavourable to the sublime, or to the highly pathetic strain.

An epic poem, or a tragedy, would be fettered and degraded by it. It is best adapted to compositions of a temperate strain, where no particular vehemence is required in

the sentiments, nor great sublimity in the style; such as pastorals, elegies, epistles, satires, &c. To these it communicates that degree of elevation, which is proper for them, and, without any other assistance, sufficiently distinguishes the style from prose. He who should write such poems in blank verse, would render his work harsh and unpleasing. In order to support a poetical style, he would be obliged to affect a pomp of language unsuitable to the subject. Dr. Blair farther observes, that though he coincides in opinion with those, who think that rhyme finds its proper place in the middle, but not in the higher regions, of poetry, can by no means join in the invectives which some have poured out against it, as if it were a mere jingling of sounds, fit only for children, and owing to nothing but the corruption of taste in the monkish ages. Rhyme might indeed be barbarous in Latin or Greek verse, because these languages, by the sonorousness of their words, by their liberty of transposition and inversion, by their fixed quantities and musical pronunciation, could carry on the melody of verse without its aid. But it does not follow, that it must, therefore, be barbarous in the English language, which is destitute of these advantages. Rhyme was barbarous in Latin; and an attempt to construct English verses, after the form of hexameters and pentameters, and Sapphics, is as barbarous among us. It is not true, that rhyme is merely a monkish invention. On the contrary, it has obtained under different forms in the versification of most known nations. It is found in the ancient poetry of the northern nations of Europe; and it is said to be found among the Arabs, the Persians, the Indians, and the Americans. This shews, that there is something in the return of similar sounds, which is grateful to the ears of the greatest part of mankind. And if any one, after reading Mr. Pope's Rape of the Lock, or Eloisa to Abelard, shall not admit our rhyme, with all its varieties of pauses, to carry both elegance and sweetness of sound, his ear must be pronounced to be of a very peculiar kind.

The present form of our English heroic rhyme in couplets is a modern species of versification. The measure generally used in the days of queen Elizabeth, king James, and king Charles I., was the stanza of eight lines, such as Spencer employs, borrowed from the Italian; a measure very constrained and artificial. Waller was the first who brought couplets into vogue; and Dryden afterwards established the usage. Waller first smoothed our verse; Dryden perfected it. Mr. Pope's versification has a peculiar character. It is flowing and smooth in the highest degree; far more laboured and correct than that of any who went before him. He introduced one considerable change into heroic verse, by totally throwing aside the triplets, or three lines rhyming together, in which Mr. Dryden abounded. Dryden's versification, however, has great merit; and, like all his productions, has much spirit mixed with carelessness. If not so smooth and correct as Pope's, it is however more varied and easy. He subjects himself less to the rule of closing the sense with the couplet, and frequently takes the liberty of making his couplets run into one another, with somewhat of the freedom of blank verse. Blair's Lect. vol. iii. See VERSE.

Rhymes are either *single*, or *double*, or *triple*, though the two last are now much diffused.

RHYMES, *Single*, are divided into perfect or whole rhymes, and imperfect or half rhymes. A *whole* or *perfect* rhyme is where there is a similitude of sound without any difference; or where a thorough identity of sound appears in the pronunciation of the two syllables, notwithstanding that there may be some difference in the orthography. A *half* or im-

perfect rhyme is where there is a similitude, with a difference either in respect of the pronunciation, or the orthography, but chiefly the former.

RHYME, *the feminine*, is that where the last syllable of the rhyme ends with an *e* mute, or quiescent, as in *dove*, *belle*, &c.

RHYMES, *Masculine*, are those of all other words.

Menage observes, that the masculine rhymes close the periods better; but the feminines, being the softer and more languishing, end more agreeably, especially in mournful subjects.

RHYMES, *Double*, by the French called *rich* rhymes, are those where the two words terminate alike through the whole two last syllables, as *squabble* and *rabble*, &c.

RHYMES, *Plain*, are those where the two rhyming verses succeed immediately to each other.

RHYMES, *Cross*, are those where the verses are so disposed, as that the first rhymes with the third, and the second with the fourth, &c.

RHYMES, *Assonant*. See ASSONANT.

RHYMNICI MONTES, in *Ancient Geography*, mountains of Scythia, on this side of Imaus, in which the river Rhymnus had its source. The mouth of this river was in the Caspian sea, between that of the river Rha and that of the river Dai.

RHYNBECK, or RHINBECK, in *Geography*, a post-town of America, in Dutchess county, New York, on the E. side of Hudson's river, opposite to Kingston; 103 miles N. of New York. The township is bounded S. by Clinton, and N. by Beckman. A curious cavern has been discovered, in 1792, at a place in this town, called by the Indians Sepacoot.

RHYNCHÆ, in *Ancient Geography*, a country of Greece, in the isle of Eubœa. Steph. Byz.

RHYNCHOSPORA, in *Botany*, so called from  $\rho\upsilon\chi\alpha\varsigma$ , a *beak*, and  $\sigma\pi\omicron\rho\alpha$ , *seed*; because the permanent base of the style forms a beak to the seed.—Vahl. Enum. v. 2. 229. Brown Prodr. Nov. Holl. v. 1. 229. Ait. Hort. Kew. v. 1. 127.—Class and order, *Triandria Monogynia*. Nat. Ord. *Calamaria*, Linn. *Cyperaceæ*, Brown.

Ess. Ch. Glumes chaffy; the lower ones empty. Corolla none. Seed one, crowned with the hardened permanent style, whose base is as broad as the seed.

Vahl, the founder of this genus, describes nineteen species, among which are *Schoenus albus* and *fuscus* of Linnæus, and Sm. Fl. Brit. Mr. Brown adopts it, adding to the character, that "the seed is accompanied at its base by toothed bristles, shorter than the glumes." He remarks, that it differs from *DICHROMENA*, (see that article,) in having these bristles. This writer defines three New Holland species, one the *R. aurea* of Vahl, and other two non-descript. The inflorescence is said to be very various, some species having the flowers panicled, whilst in others they are either corymbose, or capitate. We do not see the necessity of establishing this genus; at least, as it concerns the British Flora, we beg leave to suspend our opinion. See SCHOENUS.

RHYNCSIA, from  $\rho\upsilon\chi\alpha\varsigma$ , a *beak*, because the keel terminates in a long sharp point.—Loureir. Cochin. 460. Class and order, *Diadelphia Decandria*. Nat. Ord. *Papilionaceæ*, Linn. *Leguminosæ*, Juss.

Ess. Ch. Corolla papilionaceous. Keel rhomboid, beaked. Legume membranous, with two seeds.

1. *R. volubilis*.—Found wild near Canton in China. Stem herbaceous, round, twining. Leaves ternate, roundish, downy. Flower-stalks axillary, in pairs, many-flowered. Calyx two-lipped. Corolla yellow. Seeds black and shining.

In so difficult a tribe, we dare not answer for the permanency of this genus, not having seen a specimen. The plant may possibly be known to botanists, under some other name and genus.

**RHYNCOTHECA**, from *ῥυγχος*, a beak, and *βύκη*, a capsule, on account of its beaked or pointed seed-vessel. De Théis Gloztaire de Botanique, 402. Fl. Peruv. 71.

**RHYNDACUS**, in *Ancient Geography*, a river of Asiatic Mylia, according to Pomponius Mela, who places its source in mount Olympus. According to Pliny it had been denominated Lycus.—Also, a town of Asia, between Phrygia and the Hellespont. Steph. Byz.

**RHYNE**, in *Botany*, a name used by some authors for the camphor tree.

**RHYPÆ**, **RÏPÆ**, or *Rhyper*, in *Ancient Geography*, a town of the Peloponnesus, in Achaia, the territory of which was denominated Rhypidis. According to Strabo it was N. of Helice, and at some distance from the coasts of the gulf of Corinth. Pausanias says that in his time they could only perceive the ruins of Rhyper, 30 miles from Ægium. Homer calls this town Répe.

**RHYPARA**, an island situated near that of Samos. Pliny.

**RHYPTICS**, **RRIPTICS**, *ῥυπτικά*, in *Medicine*, detergent remedies, or cleansers. See **DETERGENT**.

**RHYSSADIUS**, in *Ancient Geography*, a mountain of Africa, in Lybia interior, in which Ptolemy places the source of the river Stachir.

**RHYSTROM**, in *Geography*, a river of Holstein, which runs into the Elbe at Glückstadt.

**RHYTHM**, **RHYTHMUS**, *ῥυθμός*, in *Music*, the variety in the movement, as to the quickness or slowness, and length and shortness, of the notes.

Or the rhythmus may be defined, more generally, the proportion which the parts of a motion bear to each other.

In *ancient poetry* rhyth or rhythm denotes the measure of the feet, or the number and combination of long and short syllables, called also *metre* and *quantity*.

A continued motion in every organized body that is capable of rhythm, is susceptible of some kind of measure. This measure marks the several parts of motion, and enables us to judge of their proportions. It is to point out these proportions that the Greeks, among many other terms, have made use of *ῥυθμός*, *rhythm*, which they have applied to different purposes. They have not only expressed by it the kind of cadence, or vibration of the wings, in the flight of birds; the movement of the feet in the progressive motion of animals; and the gestures, figures, and steps of dancers; but every species of regular motion, such as is observable in the beating of the pulse, and in respiration. They have even abused the original import of the word so far as to apply it to things absolutely motionless and inanimate; such as works in painting and sculpture, in which they have called that symmetry and just proportion which reigns in all the parts by the name of rhythm.

But the most common application of this term has been to express the *time* or duration of many sounds heard in succession; whether these sounds are musical, and such as are produced by voices and instruments, or without any determinate tone, as in the strokes of a hammer upon an anvil; in the beating of a drum; and in the articulations of the voice in common speech, in repeating poetry, or pronouncing an oration.

But our enquiries here shall be confined to that species of rhythm, which more particularly concerns melody, and which merits discussion the more, on account of its great

importance in music, and of the darkness in which it is usually involved by writers on the subject.

From the strict union of poetry and music among the ancients, which seem to have been almost inseparable, an offence against time or rhythm was unpardonable, as it not only destroyed the beauty of the poetry, but sometimes even the meaning of the words of which it was composed.

Το πᾶν πᾶρα μουσικῆ: ὁ ῥυθμός, say the Greeks; it was the principal point in their music, without which they regarded melody as wholly unmeaning and lifeless. Hence Plato refused the title of musician to every one who was not perfectly versed in rhythm, as we should now to a bad *timeist*. It is of such importance, that, without it, music can have no power over the human passions. Pythagoras, according to Martianus Capella, used to call rhythm, in music, the *male*, and Melos the *female*; and Doni has compared rhythm with *design*, in painting, and Melos to *colouring*. It is certain that an ordinary melody, in which the time is strongly marked, and the accents are well placed, has more effect than one that is deficient in those particulars, though more refined and uncommon, and set off with all the richness of harmony, and learning of modulation.

Isaac Vossius, in his Dissertation “De Poematum Cantu, et viribus Rhythmici,” has attributed to rhythm all the miraculous powers of ancient music.

As vocal music was chiefly cultivated among the ancient Greeks, the first part of these rhythmical observations shall be confined to lyric poetry.

Aristides Quintilianus defines musical rhythm *συσκευὴ ἐκ χρόνων κατὰ τὰς τάξεις συγκαταμένη*; “the assemblage of many parts of time, which preserve a certain proportion with each other;” which, since the use of bars in music, may be called aliquot parts of a measure, or a given portion of time. For the better understanding of this definition, it is necessary to remember that the music in question was constantly sung to verses, the words of which were all composed of *long* and *short* syllables; that the short syllable was pronounced as quick again as the long, and the short syllable being regarded as one part or portion of this measure, the long was equal to two; so that, consequently, the sound which was applied to the long syllable, was equal in duration to two such sounds as were sung to short syllables, or, in other words, that one note was equal to two portions of time, and the other to one. It must likewise be remembered that the verses thus sung, were composed of a certain number of feet, formed by these long and short syllables differently combined, and that the rhythm of the melody was regulated by these feet; as, whatever was their length, they were always divided into two parts, equal or unequal, the first of which was called *ἄρσις*, *elevation*, and the second *θρσις*, *depression*. A foot in poetry seems to answer to a bar in music. A *time*, among the ancients, was a proportion of that foot or bar; as, with us, a bar is divided into accented and unaccented parts. In like manner the rhythm of the melody, corresponding with these feet, was divided into two parts, equal or unequal, which we now call the *down* and *up* parts of a bar, expressed by *beating down* the hand or foot, and *lifting it up*. Thus far concerns *vocal* rhythm; what follows belongs to *instrumental*.

As the notes of the ancient music were constantly written over each syllable of the verses which were to be sung; as the quantity of each of these syllables was perfectly known to musicians; and as the duration of each sound was regulated by the syllables; it did not seem necessary that the time should be marked by any particular sign or character. However, for the ease and convenience of the musician, a

canon,

canon, or rule, was given of the rhythm at the beginning of a lyric poem. This canon consisted of nothing but the numbers 1 and 2, that is, the alpha and beta of the Greek alphabet, disposed according to the order of the breves and longs which composed each verse, and divided according to the number of its feet. The alpha, or unit, marked a breve, because it contained only one portion of time; and the beta, or binary, marked a long, being equal to two portions. Some of these poetical, or rhythmical canons, are still to be found in the Manual of Hephæstion.

Rhythm in Latin was called *numerus*; and this term, in process of time, was extended to the melody itself, subjected to certain numbers or rhythms, as appears from this line of Virgil:

“Numeros memini, si verba tenerem:”

“If I knew the words, I could remember the tune well enough.”

The Romans had signs for rhythm, as well as the Greeks; and these signs were not only called *numerus*, but *æra*, that is, *number*, or the mark for time. *Numeri nota*, says Nonius Marcellus. In this sense we find the word used in a verse of Lucilius:

“Hæc est ratio? perversa æra? summa subducta improbe?”

“Do you call that settling accounts? such a confusion of figures? and the sum falsely cast up?”

Though the word *æra* was at first only applied by musicians to the time, or measure of the melody, they afterwards made the same use of it as of *numerus*, to express the tune or melody itself; and it has been thought that the word *air*, or, as the Italians call it, *aria*, which includes a certain piece of music of a peculiar rhythm, or cadence, is derived from *æra*.

Such was the manner in which the ancients marked the measure in their written music; but to make it still more sensible in the execution, they beat time in several different ways. The most common was by the motion of the foot, which was lifted up and beat down alternately, according to what we call common, or triple time. To regulate the time was generally the office of the music master or director, called *μυσοχορος* and *κορυβαίης*, *coryphaeus*, because he was placed in the middle of the orchestra, among the musicians, and in an exalted and conspicuous situation, in order to be seen and heard the more easily by the whole band.

The directors of the time were likewise called in Greek *ποδοκτυπαι* and *ποδοδμοι*, from the noise of their feet. In Latin they were called *pedarii*, *podarii*, and *pedicularii*, for the same reason. Their feet were generally furnished with wooden or iron sandals, in order to mark the time in a more distinct manner; these implements the Greeks called *κρηπίδες*, *κρηπίδα*, *κρηπίδα*; and the Latins *pedicula*, *scabella*, or *scabilla*, because they resembled little pattens, or clogs.

But it was not only with the feet that the ancients beat the time, but with all the fingers of the right hand upon the hollow part of the left; and he who marked the time or rhythm in this manner, was called *manu-duktor*. For this purpose they sometimes used oyster-shells, and the shells of other fish, as well as the bones of animals, in beating time, as we do of castanets, tabors, &c. Both Hesychius, and the scholiast of Aristophanes, furnish passages to confirm this assertion. What a noisy and barbarous music! All rhythm, and no sound. The drums and sistrums of the Idæi Dactyli could not have been more savage.

Many ancient instruments were monotonous, and of little use, but to mark the measure; such were the cymbalum and

sistrum; and it was for this reason, perhaps, that the cymbal was called *æra*, by Petronius. But it would afford us no very favourable idea of the abilities of modern musicians, who should require so much parade and noise in keeping together. The more time is beat, says M. Rousseau, the less it is kept; and, in general, bad music, and bad musicians, stand most in need of such noisy assistance.

However, if any thing like the power which ancient music is said to have had over the passions can be credited, it must have derived this power chiefly from the energy and accentuation of the rhythm. Aristides Quintilianus gives a long list of different metres, with their several properties of calming or agitating the mind, according to the nature of the syllables, or feet of the verses, as well as the sentiments which they were intended to express; and as it will afford the reader an opportunity of seeing how much stress was laid on this part of music, and how fanciful and ideal many of the distinctions seem to have been, we shall give the whole passage in English.

“Measure, which begins by a *down part* of the metrical division, is calm and gentle; whereas that which begins by an *up part*, expresses trouble and agitation. Full time, that is, always accompanied with melody, is noble in its effect; and that arising from catalectic verses, deficient in a syllable or note, if it be supplied by a rest or pause, has more simplicity. Time of equal proportions, is graceful; and that of odd numbers, or sesquialterate proportion, is more proper to excite commotion. Double time is a kind of mean betwixt the graceful and the turbulent. Among the movements of two even notes, if they are short, their effect is lively, impetuous, and proper for military dances, called *Pyrrhics*, in which the dancers are armed; and time, of which the movement is regulated by poetic feet composed of long syllables, is more grave, serious, and fit for hymns which are sung in honour of the gods, at festivals, and in sacrifices; the measure composed of a mixture of long and short notes, participates of the qualities of both these last mentioned.

“Among the duplicate proportions, the Iambic and Trochaic have the most vivacity and fire, and are peculiarly proper for dancing. Those called *οβρις* and *σημαντοι*, of which the arsis answers to two long syllables, are full of dignity. Compound measures are more pathetic than simple; and such as are confined to one genus, move the passions much less than those which pass from one genus to another.”

After giving these characteristics of time, Aristides proceeds to prove their reality and foundation in nature, by drawing a parallel between some particular species of rhythm, and the gait and actions of man. He pretends, for instance, “that the motion which answers to the Spondaic measure, is a sign of moderation and fortitude; that Trochaics, or Pæans, indicate a greater degree of fire and vivacity; that the Pyrrhic has something low and ignoble in it; that an irregular velocity implies dissoluteness and disorder; and finally, that a movement resulting from all these, is wild and extravagant.”

With respect to the excellence and effects of ancient music, it is very difficult to steer between the extremes of credulity and scepticism. Such enthusiasts as Aristides Quintilianus, by asserting too much, have thrown a ridicule upon the subject, and inclined us, perhaps, to believe too little. The simplicity of ancient melody, and its slavish dependence upon poetry, may probably have given birth to some of these fancies.

In addition to the account already given of the poetic feet under their respective articles, we shall here introduce a  
short

# RHYTHM.

short description of each as they more immediately relate to music, at the same time rendering our dissertation on rhythm more complete.

A poetical foot consists of a certain number of syllables, which constitutes a distinct part of a verse, as a bar does of an air in music. An hexameter verse consists of six of these feet, a pentameter of five.

The Spondee, Iambus, Trochee, and Pyrrhic or Periambus, are dissyllabic feet, or of two syllables each.

The Spondee consists of two long syllables, as *vertunt*. --

An Iambic foot has one short and one long syllable. *Θεῶν, λειψῶν. potens, amas.* ~ -

return.

The Trochee has one long and one short syllable, as *gratus, musa.* - ~

silent.

The Pyrrhic, or Periambus, two short syllables, as *mare, probus.* ~ ~

quiver.

The Daetyl, Anapæst, Molossus, Tribrach, Bacchius, Antibacchius, Amphibrachys, and Creticus, are trisyllabic, or of three syllables. To some of these we have no equivalents; however, the Daetyl, consisting of one long

and two short syllables ~ ~ ~ is very com-

mon in our language, as *tenderly, hastily*; and we have verses composed of daetyls as well as the Greeks and Romans:

*Mÿ | bānks thÿ wÿre | fÿrnish'd with | beēs,  
Whōse | mÿrmÿrs in- | vitē òne tò | sleēp.*

These may be compared with the following celebrated passages in Homer and Virgil, where the sound is manifestly, and intentionally, an *echo to the sense*. Homer (*Odyssæy*, book xi.) after he has described in labouring Spondees the slow and painful manner in which Syphilus rolled the stone up hill, makes use of nimble Daetyls in describing its swift descent:

*Αὔθι; ἐπιτόσ' πτόσ' ὀδοῖ κῦλινδ' ἐπ' ἑλᾶς ἀναίδης.*

And Virgil, lib. viii. v. 596, describes, in pure Daetyls, the galloping of the horse:

"----- It clamor, et ægmīnē fāctō  
Quādrupēdāntē pūtrēm sonitū quātīt ūngulā cāmpūm."

The Anapæst has two short and one long syllable; as

*sapiens, recubans,* ~ ~ ~  Isaac Vossius,

"De Viribus Rhythmī," p. 56, has said, that the French have no Daetyls, nor the English a perfect Anapæst in their language. Let the French speak for themselves; but as to our own part of the charge, it is easily confuted by the mere mention of the words *recommend* and *disappoint*.

We shall enumerate the rest of the poetic feet of the

ancients, merely to shew what resources they had in varying their melody by different combinations of two kinds of notes.

The Molossus has three long syllables, ---

The Tribrach, three short, ~ ~ ~

The Bacchius, which is the reverse of the Daetyl, has one short, and two long syllables, ---

The Antibacchius, two long and one short, ---

Amphibrachys, one short, one long, and one short, or one long between two short, ~ ~ ~

Creticus, one short between two long, ---

The quadrifyllabics are compounded of feet already mentioned.

The Proceleusmaticus is composed of four short syllables, or of two Pyrrhics, ~ ~ ~ ~

The Choriambus, two short between two long, or the junction of the Trocheus and Iambus, ~ ~ ~ ~

Epitrite; of this foot there are four species: 1. The Iambus and Spondee ~ ~ ~ ~: 2. The Trochee and Spondee ~ ~ ~ ~: 3. The Spondee and Iambus ~ ~ ~ ~: and 4. The Spondee and Trochee ~ ~ ~ ~.

The Pæan or Pæon, which is the contrary of this last, consists of one long syllable, and three short: ~ ~ ~ ~, ~ ~ ~ ~, ~ ~ ~ ~.

Servius reckons more than a hundred different kinds of verse among the Latins; and, according to Hephæstion, the number was still more considerable among the Greeks; consequently their melody might have been varied in as many different ways. There is not, however, the least appearance of the ancients having had in their vocal music that kind of measure which we call pointed; nor did they admit rests in the middle of a verse, though at the end of catalectic, or broken verses, the finger was allowed to make up the deficiency by a silence, equivalent to a rest in modern music; and though they had so great a variety of feet in their poetry, many of those already instanced are unfit for modern melody.

"After all the researches," says Dr. Burney, "which I have been able to make, it must be acknowledged that the subject of ancient music, in general, still remains, and probably ever will remain involved in much difficulty and uncertainty. It is fortunate, however, for those who wish to view as near as possible this dark angle of antiquity, that the prospect happens to be the clearest just in that part where all its admirers assure us it is best worth examining;

or however ignorant we may be of the melody of ancient music, the rhythm, or time of that melody, being regulated entirely, as has been already observed, by the metrical feet, must always be as well known to us as the prosody and construction of the verse; so that we have nothing to do but to apply to the long and short syllables any two notes, one of which is double the length of the other, in order to know as exactly as if we heard, in what manner any particular kind of metre was set by the ancients with respect to time and cadence, that boasted rhythm, which we are so often told was every thing in their music. It may, therefore, afford some gratification to the curiosity of those who have never considered the poetry of the ancients in this point of view, if I produce a few examples, which will, perhaps,

help to throw a little light upon the dramatic music of the Greeks, and give some idea of the rhythmical resources of the poet-musician in one of the most interesting provinces of his art.

“The first example shall be of the Iambic verse, which chiefly prevails in the Greek tragedies, and in which the dialogue and soliloquy, indeed all but the chorus and ode, were generally written. I shall content myself with applying notes of correspondent lengths to the syllables, and marking the time; leaving the melody to the imagination of the reader. Should I presume to supply it, I might expect to be reproached as another Salmoneus for my temerity.

“Demens! qui nimbos et non imitabile fulmen, &c.”

This measure, when pure and unmixed, consisted of six Iambic feet, as,

æquē | fōnān|tē vēr|bērā|bit ūn|gūlī.

Such verses, however, seldom occur. The laws of this metre only required that the second, fourth, and last feet should be Iambics; in the other places, Spondees, Anapaests, and Dactyls, were admitted. This metre answers to our Alexandrine, or verse of twelve syllables; but more exactly in the number and kind of feet, than in its cadence, or general effect upon the ear. The pause after the third foot, so essential to a melodious Alexandrine, has no place but by accident, in the Iambic, which runs more swiftly, and has a more profane effect. This, undoubtedly, led the ancients to measure it per dipodiam, or by double feet (see Hor. Art. Poet. v. 252. pes citus: unde, &c.), which answer to double bars in modern music. Aristotle wrote some comedies in this Iambic measure. One of his lines will, perhaps, be as exact a representation of the ancient Iambic as can be produced, in point of cadence.

Per dio son qua|si in pensier di | tornarmeue.

The following Alexandrine of Spenser may also serve for the same purpose.

“So in his angry courage fairly pacified.”

The above Greek lines are the beginning of the Hecuba of Euripides, and were sung by the ghost of Polydorus. The bars in the verse are only to shew how the ancients divided it into three portions of two feet in each; but the bars of time, the thesis, or beat, must always fall in the middle of the foot: ~ | - ♩ | ♩. For the sake of distinguishing the feet more clearly, Dr. Burney barred them singly; though it would have been more conformable to the ancient manner

of scanning this kind of verse, and probably more expressive of its cadence and effect, to have made but three bars in each line. The Iambics of Greek comedy differ from these only in a little more liberty of construction; those of the Roman, in Plautus and Terence, are so licentious, as often not to differ perceptibly from prose, even in the judgment of Cicero himself: “propter similitudinem sermonis, sic sæpe sunt abjecti, ut nonnunquam vix in his numerus et versus sentiri possit.” Orator, cap. 55.

Besides this metre, the dialogue admitted, occasionally, Trochaic verses. They are generally introduced in scenes of hurry and disorder; being, as Aristotle has described them, and as their name implies, a voluble and dancing measure. A character which the reader will not be inclined to dispute, when he compares the ancient Trochaic with a measure exactly corresponding to it in our own language, but which we have not yet admitted into our tragedy.

Πῆ ῥῆν ὄτῳ; ὄ; πῆρῶν; | τῆμῶν ἐκ δόμων ἔξῆρῳ;

This is a pure Trochaic, and is precisely in the measure of our

“Jolly mortals fill your glasses,  
Noble deeds are done by wine.”

The whole difference is, that the ancient Trochaics were written in one line; but this is merely to the eye; for they really consist of two verses; the last syllable of the fourth foot being, as Dr. Burney believes, constantly, the end of a word.

Mr. West, in his translation of the “Iphigenia in Tauris” of Euripides, has given a whole scene of Trochaics in the correspondent English measure. A single line of the original, with his translation, will be a sufficient example of Trochaic rhythm.

# RHYTHM.

Such were the metres appropriated to the dialogue of the ancient tragedy, and such must have been the rhythms or times of the music to which they were set.

We shall clofe these observations with one example more, taken from the *choral* part of the drama, that part which was more particularly *musical*, and the circle marked out for the musician, where all the magic of his art, with all the wonders of rhythm, were to be displayed. Of the metre of this part, we shall only observe, in general, that it seems to have admitted of such an unbounded variety in the mixture and arrangement of feet, and to have been fettered by so few restraints, that, to a modern ear, it is frequently not to be distinguished from a smooth and elegant prose. We can therefore be certain of nothing, concerning the music applied to the ancient chorus, except the *relative lengths* of the notes as they are determined by the prosody: in what manner the ancients divided them by beats, we do not even presume to guess; and we believe it may be proposed to the musical reader as a problem, worthy, for its difficulty at least, if not for its importance, to exercise his sagacity, how the following specimen should be *barred*, in order to render it as little tormenting to the ear as possible.

Ω γῆ - νῆ - αἰ βροτῶν, ὤρι, ὑμᾶς ἔ - σα καὶ τὸ μῆδεν.

Ζεῦ πάτερ ἔ - νῶ - ριβμῶ.

Τίς γὰρ, τίς ᾄ - νῆρ παλῆ - ὄν.

Τῶς, εὐδαί - μῶ - νῶ - ᾄς ῥῆ ρῆι.

Πι τὸ - σῆτον ὄ - σὸν δόκτεν.

Καὶ δόξάντ' ᾄ - ποκ λι - ναί.

The most striking circumstance in all these examples, is the perpetual change of time, occasioned by the mixture of unequal feet. To the eye, indeed, the recitative of the old French opera presents a similar appearance; but where no strict time is observed, the changes are less perceptible to the ear. No circumstance relative to ancient music has been more frequently and triumphantly opposed to the modern, in proof of superiority, than its inviolable adherence to the *fixed quantity* of syllables. It is, perhaps, equally difficult to disprove this, and to conceive how such a music could be rigorously executed, without throwing both the hearers and performers into convulsions. If, however, this was the case,

we need no longer wonder at the noisy expedients, to which the ancients had recourse in beating time; for we believe the best modern band would find it difficult, if not impossible, to keep exactly together in the execution of a Greek chorus, though assisted by all the clatter of an ancient coryphæus.

Upon the whole, perhaps, even the imperfect view which we have here attempted to give of the rhythmical resources of ancient music, may be sufficient to warrant something more than a doubt, whether, after all that Isaac Vossius, and many others, have said, a *fixed prosody*, and the rigorous, unaccommodating length of syllables, be any recommendation of a language for music; that is, whether a music formed and moulded closely upon such a language, must not necessarily be cramped and poor, in comparison of that free, unshackled variety; that independent range of rhythmical phrase, which constitutes so considerable a part of the riches of *modern* music. Let the most inventive composer try to set half a dozen Hexameters, pure Iambics, or any other verses that will fall into regular common or triple time, and he will soon find that no resources of melody are sufficient to disguise or palliate the insipid and tiresome uniformity of the measure; and as for any thing like expression, we may as well expect to be affected by the mechanical strut of a soldier upon the parade. In other metres, such as those already given in the preceding examples, where feet of different times are intermixed, *some* variety is indeed acquired; but it is a misplaced variety, which, without obviating the tiresome effect of a confinement to no more than *two* lengths of notes, adds to it that of an awkward and uncouth arrangement; the ear is still fatigued with uniformity where it requires change, and distracted by change where it requires uniformity.

Modern music, on the contrary, by its division into *equal* bars, and its *unequal* subdivision of these bars by notes of various lengths, unites to the pleasure which the ear is by nature formed to receive from a regular and even measure, all the variety and expression which the ancients seem to have aimed at by sudden and convulsive changes of time, and a continual conflict of jarring and irreconcilable rhythms.

Nothing seems more essential to musical pleasure, than the division of melody into equal portions of time, or bars. Quintilian attributed to this natural mensuration of the ear, the first production of poetry: "Poema—aurium mensurâ, et similiter decurrentium spatiorum observatione esse generatum." Hexameters and Iambics appear to have been the most ancient Greek metres; and the latter, if we may credit Horace, Art. Poet. 253, were at first *pure* and uncompounded. The mixture of *unequal* feet, and the Dithyrambic licence of lyric poetry, were later refinements. The progress of musical rhythm was, of course, the same. Plutarch expressly says, in the dialogue de Musica, that the compositions of Terpander, and other old masters, were set to Hexameters, chiefly of Homer; that is, they were in regular common time. The change and intermixture of rhythms is spoken of as the innovation of modern artists. Plato rejects these complicated measures from the music of his republic; and even Isaac Vossius, the great champion of ancient rhythm, who asserts that "no man can be a good musician, that is not a *good drummer*," owns, p. 11, that "vitiosum et incompositum imprimis, fiet carmen, si duorum, trium, quatuor, pluriumve temporum pedes, veluti Pyrrichii, Iambi, Daetyli, Pæones, Iunci, simul copulerentur;" though this is done continually, not only in the lyric part, but even in the dialogue of the ancient drama.

It is evident, from the proofs already given, that the Greeks and Romans had but two different degrees of long and short notes; and even the old lozenge and square characters

acters still used in the *canto fermo* of the Romish church, under the denomination of Gregorian notes, are but of two kinds; the time of these may, indeed, have been accelerated or retarded, but still the same proportion must have been preserved between them; and all their variety must have arisen from different combinations of these two kinds of notes, such as any two of ours could afford; as semi-breves and minims, minims and crotchets, or crotchets and quavers.

This accounts for the facility with which even the common people of Greece could discover the mistakes, if any were committed, in the length and shortness of the syllables, both with respect to the poetry, and the music, a point of history in which all writers agree; for besides the intervals peculiar to the melody, rhythm, or time, must have contributed to characterize the modes, though it has no kind of connection with our flat and sharp keys; and this gives an idea quite different from what our modern modes, taken as keys, and our music, in general, furnish. Tartini, upon this subject, says, that we make the profody subservient to the music, not the music to the profody; and adds, "that as by the laws prescribed to the ancient musicians, they were obliged to preserve rigorously in their music the quantity of syllables, it was impossible to protract a vowel, in singing, beyond the time which belonged to a syllable; we, on the contrary, prolong the vowels through many bars, though in reading they are oftentimes short."

Tartini, however, in pure courtesy, allows to the ancients a discretionary power of making syllables longer or shorter than rigorous time would admit, in order to diversify expression, and to enforce the passion implied by the words; but if time was rigorously beaten, in the manner the ancients have related, it is not very easy to subscribe to this opinion.

Having explained the nature, difference, and properties of ancient rhythm, Dr. Burney bestows a few words on an examination of the modern, and endeavours to shew what it has, in common with the ancient, and what peculiar to itself.

We no longer know rhythm now under its ancient name; however, it has been continued, with a small change of pronunciation, merely to express the final cadence of verses, or the agreement and similarity of sound in the last syllables of two or more lines in poetry; being at present what we call *rhyme*; whereas the proportion subsisting between the different parts of a melody are called *time, measure, movement*.

And when we come to examine this proportion, we find that it only consists of two kinds, differently modified; and these two are known by the names of *common time*, consisting of equal numbers, and *triple time*, of unequal.

Tartini has deduced all measure from the proportions of the octave and its fifth. "Common time, or measure," says he, "arises from the octave, which is as 1 : 2; triple time arises from the fifth, which is as 2 : 3. These," adds he, "are the utmost limits within which we can hope to find any practicable proportions for melody. Indeed many have attempted to introduce other kinds of measure, which, instead of good effects, have produced nothing but the greatest confusion; and this must always be the case. Music has been composed of five equal notes in a bar, but no musician has yet been found that is able to execute it."

By the improvement of instrumental music, and indeed by the liberties which we have taken with poetry in singing, we have multiplied notes, and accelerated the measure. Instead of one sound to one syllable, or one portion of time for a short syllable, and two for a long one, we frequently divide and subdivide the time of these several portions into

all their aliquot parts, and sometimes into incommensurable quantities.

After the invention of musical characters for time, different from those in poetry, the study of their relations became one of the most laborious and perplexed parts of a musician's business. These characters were of different value and velocity, according to other characters placed at the beginning of a musical composition, and likewise frequently occurring in the course of a piece, to announce a change of measure; as from common time to triple, from quick to slow, or the contrary. These characters were called *moods*, but they were so extremely embarrassing and ill understood, till the invention of bars, by which musical notes were divided into equal portions, that no two theorists agreed in the definition of them.

These modes, by which the kind of movement, with respect to quick and slow, as well as the proportions of the notes, used to be known, since the use of technical terms, chiefly taken from the Italian language and music, has been adopted, serve no other purpose than to mark the number and kind of notes in each bar.

But by this invention of musical characters for time, and the use of bars, we have certainly advanced in the performance of instrumental music, by giving to it more energy and accentuation; it has now a cadence and feet of its own, more marked and sensible than those of poetry, by which it used to move.

We have also, in our *airs*, a distinct species of music for poetry, wholly different from recitative and chanting; for in these we are no more tied down to stated measure than the ancients, but are governed by the accent and cadence of the words. However, our florid-song, it cannot be dissembled, is not always sufficiently subservient to poetry; for in applying music to words, it frequently happens that the finest sentiments and most polished verses of modern languages are injured and rendered unintelligible, by an inattention to profody. Even the simple and plain rules of giving a short note to a short syllable, a long to a long; and of accentuating the music by the measure and natural cadence of the verse, which the mere reading would point out to a good ear and understanding, are but too frequently neglected.

Modern melody requires, perhaps, more than a single sound to a single syllable; and a fine voice deserves, now and then, a long note to display its sweetness; but this should be done upon long syllables, and to open vowels, and, perhaps, in general, after the words have been once simply and articulately sung, for the hearer to know what passion is intended to be expressed, or sentiment enforced, by future divisions.

Expletives, particles, and words of small importance, are forced into notice by careles or ignorant composers, who, only intent upon mere music, pay no regard to her sister, poetry. But then, poetry, in revenge, is as little solicitous about musical effects; for symmetry of air, or simplicity of design, are generally so little thought of, that every heterogeneous idea, which can be hitched into rhyme, is indiscriminately crowded into the same song. Indeed music and poetry, like man and wife, or other associates, are best asunder, if they cannot agree; and on many occasions, it were to be wished, that the partnership were amicably dissolved.

Salinas tells us, from St. Augustine, that poets and musicians have ever been at strife concerning long and short syllables, accents, and quantity, since they have ceased to be united in one and the same person, and have set up different interests.

There is some poetry so replete with meaning, so philosophical,

sophical, instructive, and sublime, that it becomes wholly enervated by being drawn out to a tune, which affects no part of the head, but the ear.

And there is, again, some kind even of instrumental music, so divinely composed, and so expressively performed, that it wants no words to explain its meaning; it is itself the language of the heart and of passion, and speaks more to both in a few notes, than any other language composed of clashing consonants, and insipid vowels, can do in as many thousand.

And, upon the whole, it seems as if poetry were more immediately the language of the head, and music that of the heart; or, in other words, as if poetry were the properest vehicle of instruction, and modulated sound that of joy, sorrow, and innocent pleasure. "Let the musician," says M. Rousseau, "have as many images or sentiments to express as you please, with few simple ideas; for the *passions* only *sing*, the *understanding* speaks."

But, notwithstanding both poetry and prosody are so frequently injured by injudicious composers, it must not be imagined that in our simple airs of the gavot and minuet kind, we have no musical rhythm, or that it always clashes with the poetical. Innumerable instances may be given from well-known English songs, where the cadence of the verse, and even the pronunciation of each syllable, is carefully preserved by the air. For though our time-table furnishes six different degrees of long and short notes, without points, yet, if the divisions in songs designed to display a particular talent for difficult execution be excepted, we seldom use more than *two* kinds of notes in the same air.

"Mirth, admit me of thy crew," by Handel, as well as several popular songs by Dr. Arne, Mr. Jackson, and others, are sufficiently conformable to poetical numbers and rhythm, to satisfy the greatest admirers of ancient simplicity, or even such as love poetry better than music, from whom complaints of non-conformity generally proceed.

Isaac Vossius says it is now above a thousand years since musicians have lost that great power over the affections, which arose only from the true science and use of rhythm; and he accuses in modern music of such a want of time and accent, as to be all of one style and colour. We will not defend the age in which Vossius wrote from the charge, nor the music of the present serious opera in France; but the compositions of Italy and Germany are certainly free from the censure, as music is now more divided into phrases, and sentences, than it was; time is more marked, and more easily felt than it has ever been since the days of Guido. What it was before, is not very well known; but to confess the truth, it is our opinion, that whatever it has comparatively lost in some particulars, it has gained in others.

**RHYTHMICA**, **RHYTHMICE**, *ῥυθμικα*, in the *Ancient Music*, that branch of music which regulated the rhythmus. See the preceding article.

**RHYTHMOPŒIA**, one of the musical faculties, as they are called, which prescribes rules for the motions, or rhythm.

The ancient rhythmopœia is very defective. We find nothing of it in the books of the ancients, but some general hints, which can scarcely be called rules. In their explanations there appears nothing but what belongs to the words and verses of their songs, which is a strong presumption they had no other. See **RHYTHM**.

**RHYTIDOSIS**, formed of *ῥυτιδος*, *to wrinkle*, the name of a distemper of the eye, in which it waxes and wrinkles up.

**RHYTIS**, in *Botany*, from *ῥυτις*, *a channel*, or *furrow*, so named by Loureiro, because it has a furrowed berry.

—Loureir. Cochinch. 660.—Class and order, *Polygamia Dioecia*. Nat. Ord. . . .

Gen. Ch. Perfect Flowers, *Cal.* Perianth inferior, cloven into from three to six, obtuse, spreading segments. *Cor.* none. *Stam.* Filaments three, thread-shaped, erect, longer than the calyx, attached to the receptacle; anthers two-lobed. *Pist.* Germen superior, rather long; style none; stigmas three, cloven, reflexed. *Peric.* Berry flatly ovate, rugose, flaccid, with one cell, and three, ovate, small seeds.

Female Flowers on a separate plant, *Cal.* Perianth inferior, cloven into numerous, lanceolate, hairy, spreading segments. *Cor.* none. *Stam.* none. *Pist.* and *Peric.* as in the perfect flowers.

Ess. Ch. Calyx from three to six-cleft. Corolla none. Stamens three. Stigmas three. Berry three-seeded.

Female, Calyx cloven into many segments.

1. *R. fruticosa*. Shrubby Rhytis. Loureir. Cochinch. 660.—Native of woods in Cochinchina.—A *shrub* about six feet high. *Stem* nearly erect, branched in a spreading manner. *Leaves* alternate, ovate-oblong, slightly pointed, smooth, entire. *Flowers* in long, slender, crowded, terminal spikes. *Berry* channelled.

**RHYTIUM**, in *Ancient Geography*, a town of the island of Crete.

**RHYZELIUS**, **ANDREW**, in *Biography*, a learned Swedish bishop, was born in West Gothland in 1677, and studied at Upsal. In 1711 he was appointed professor of theology at Abo, from thence he proceeded to Upsal, where he was ordained, and appointed under pastor of the congregation of St. Nicholas at Stockholm. In 1713 he was nominated by Charles XII. to be one of his chaplains, whom he afterwards accompanied to Norway. He obtained other high offices, and at length, in 1743, he was raised to the episcopal bench. He died in the year 1761, leaving behind him a high character for deep learning and accurate judgment. His works are numerous, some of which are, 1. "Svio-Gothica munita," or an historical description of the towns, fortresses, castles, and royal palaces in the kingdoms of Sweden and Gothland. 2. "Monasteriologia Svio-Gothica," or a description of monasteries. 3. "Mnemonica Historiæ Svio-Gothica Epitome." 4. "Episcoposcopia Svio-Gothica," or a chronicle of the Swedish bishops. Gen. Biog.

**RIACA**, or **RIAZA**, in *Geography*, a river of Spain, which rises in the mountains which separate Old and New Castile, and runs into the Duero near Roa.

**RIADHIAT**, in *Modern History*, a superstitious practice among the Mahometans, and chiefly among those of Hindoostan, which consists in shutting themselves up for fifteen days, without any other nourishment than bread and water, in a place where there is no light; during which time, the devout Mussulman incessantly repeats the word *hou*, which denotes one of the attributes of God.

**RIAITTE**, in *Geography*, a town of France, in the department of the Lower Loire, and chief place of a canton, in the district of Ancenis; 12 miles N. of Ancenis. The place contains 613, and the canton 5555 inhabitants, on a territory of 150 kilometres, in 5 communes.

**RIAL**, in *Commerce*. See **REAL**.

**RIAL**, or *Royal*, is also the name of a piece of gold anciently current among us for ten shillings.

In 1 Henry VI. by indenture of the mint, a pound weight of gold of the old standard was coined into 45 rials, passing for ten shillings a-piece, or a proportional number of half rials, passing at five shillings a-piece; or rial farthings, which went at two shillings and two-pence.

In 1 Henry VIII. the gold rial was ordered to pass at eleven shillings and three-pence. In 2 Elizabeth, gold rials were coined at fifteen shillings a-piece, when a pound weight of old standard gold was to be coined into 48 rials. In 3 James I. rose-rials of gold were coined at thirty shillings a-piece, and spur-rials at fifteen shillings.

RIALEJO, in *Geography*, a town on the W. coast of the island of Teneriffe.

RIALEJO, or *Ria Lexa*. See REALEJO.

RIALP, a town of Spain, in the province of Catalonia.

RIANA, in *Botany*, a genus of Aublet's; but that author gives no account, or reason, why it is so called. We presume this may be its common name in Guiana.—Aubl. *Guian.* 237. Juss. 287. Lamarek *Illustr.* t. 135.—Class and order, *Pentandria Monogynia*. Nat. Ord. *Berberides*, Juss.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, cloven into five, roundish, acute segments. *Cor.* Petals five, ovate, acute, joined at the base. Nectary of five scales. *Stam.* Filaments five, very short, inserted at the base of the nectary; anthers ovate-oblong, nearly sessile, two-celled. *Pist.* Germen superior, ovate, villous, with five streaks; style fleshy; stigma capitate, obtuse. *Peric.* Capsule oblong, of one cell, and three valves, compressed in the middle. *Seeds* three.

Obf. Aublet describes the five-scaled nectary, as five inner petals.

Ess. Ch. Calyx deeply five-cleft. Petals five. Nectary composed of five scales. Anthers nearly sessile. Capsule of one cell and three valves. Seeds three.

1. *R. guianensis*. Aubl. *Guian.* t. 94.—Native of woods in Aroura, where it flowers in August. This shrub is ten feet high, and has a branched trunk. Branches erect, knobbed. Leaves opposite, stalked, ovate-oblong, acute, toothed, smooth, rigid. *Stipulus* short, twin, opposite, acute, deciduous. Flowers white, arranged in an alternate manner, forming a terminal spike; each flower on a short stalk, which has four scales or bracteas at the base.

Jussieu suspects that this plant may be akin to *Passoura*, Aubl. *Guian.* t. 380.

RIANANTLA, in *Geography*, a town of Mexico, in the province of Tlascala; 60 miles S. of Puebla de los Angeles.

RIANJO, a town of Spain, in Galicia, at the mouth of the Ulla; 23 miles S.W. of Compostella.

RIANO, a town of Italy, in the Patrimonio; 13 miles N. of Rome.—Also, a town of Naples, in Abruzzo Ultra; 8 miles W. of Teramo,

RIANS, a town of France, in the department of the Var; 10 miles N.W. of St. Maximin.

RIAO, an island in the East Indian sea, about 25 miles in circumference, near the W. coast of Morty. N. lat. 2° 25'. E. long. 128° 2'.

RIAPA CREEK, a river of West Florida, which runs into the Mississippi, N. lat. 31° 2'. W. long. 91° 17'.

RIAVIA, a mountain of Africa; 60 miles W. of Tripoli.

RIAZAN, a town of Russia, and capital of a government, on the Oka; 80 miles S.S.E. of Moscow. N. lat. 34° 45'. E. long. 38° 54'.

RIAZANSKOE, a government of Russia, bounded on the N. by Vladimirskoi, on the E. and S. by Tambovskoi, and on the W. by Moskovskaia and Talskoe; 108 miles from N. to S. and 100 from E. to W. N. lat. 54° 40' to 55° 20'. E. long. 38° to 41°.

RIAZSK, a town of Russia, in the government of

Riazan; 56 miles S.E. of Riazan. N. lat. 54°. E. long. 40° 4'.

RIB, in *Rural Economy*, the small arched bones forming the chests of animals. Cattle and most other animals should be full in the rib.

In horses the chest or barrel formed by the ribs should be full and circular, taking their fullness quite from the back-bone. See HORSE.

RIB-Furrowing, in *Agriculture*, a mode of ploughing somewhat similar to that of ribbling.

RIB-Grafs, a sort of grafs much cultivated in some districts, and which is said to afford an herbage of which cattle are very fond. It is also asserted to be useful as a grafs for milch cows, and also for fattening any sort of stock. It is an indigenous plant in this country, which frequently abounds in pasture or meadow lands where the soil is rather inclined to moisture. See PLANTAGO.

In the mode of cultivating it as a grafs for cattle food under the modern system of husbandry, from four to six pounds of seed are sated by Mr. Donaldson to be sown upon the acre. It is a coarse sort of grafs, however, that requires to be kept well fed down, in order to render it valuable and prevent its running to seed.

In Cheshire some farmers are fond of it, while others think that its place would be better supplied by some of the other grasses. In some places, some fields are sown with it, nearly without any admixture of grafs seeds; and where plentiful crops of it have been produced no animal would eat it, which is supposed probable from its nature. And in the Staffordshire agricultural report, it is said that there is authority for asserting that cattle will not eat its leaves, but it is believed to be grateful in admixture with other herbage.

RIBA, or RIBAS, in *Geography*, a town of Spain, in New Castile, on the Xaramo, founded by William de Ribas of Segovia, a celebrated commander, in the year 1100; 9 miles from Madrid.

RIBA de Sella, a small sea-port of Spain, in Asturia, on the coast of the Atlantic; 36 miles E.N.E. of Oviedo. N. lat. 43° 28'. W. long. 5° 18'.

RIBADAVIA, a town of Spain, in Galicia, famous for its vineyards, which are said to produce some of the best wine in Spain; 15 miles S.W. of Orense.

RIBADENEIRA, PETER, in *Biography*, a Spanish Jesuit, was a native of Toledo. He studied at Paris and at Padua, after which he taught rhetoric with reputation at Palermo. He died at Madrid in 1611, aged 81. His works are "Lives of the Saints," folio, 1616; the "Lives of St. Ignatius Loyola, St. Francis de Borgia, and of the Father Lainez and Solmeron;" "A Treatise of the Schism of England;" another entitled "The Prince," which is full of bad political maxims; and the "Library of Writers among the Jesuits," 8vo.

RIBADEO, in *Geography*, a sea-port town of Spain, in Galicia, at the mouth of the Eo, with a good harbour defended by two castles; 15 miles N.E. of Mondonedo. N. lat. 43° 33'. W. long. 7° 5'.

RIBAGNAC, a town of France, in the department of the Dordogne; 5 miles S. of Bergerac.

RIBAGORZA, a district of Spain, bordering on the E. part of Aragon, and W. part of Catalonia; watered by the river Noguera de Ribagorza, about 40 miles long and 18 wide, N. of Balaguers.

RIBAN, an island in the Red sea, near the coast of Arabia. N. lat. 17° 12'.

RIBATTUTA, Ital. in *Music*, is iterating, striking, or sounding the same note again.

RIBATTUTA *di Gola* is one of the graces used in sing-

ing; it is performed by beating or striking two diatonic notes, the one slow and the other quick, in the following manner.

It differs from the shake and the beat.

RIBAUEQUEM, in *Ancient Artillery*, a projectile machine used in the 11th and 12th centuries, which was a large kind of cross-bow: the cross-bow was called in Latin *ballista*, and sometimes *manubalista*.

RIBAUVILLE', in *Geography*, a town of France, in the department of the Upper Rhine, and chief place of a canton, in the district of Colmar; 6 miles N. of Colmar. The place contains 4950, and the canton 14,219 inhabitants, on a territory of 85 kilometres, in 9 communes.

RIBBAND, or RIBBOND, a narrow sort of silk, chiefly used for head ornaments, badges of chivalry, &c.

The knights of the Garter wear a blue ribband; those of the Thistle, a green ribband, &c. scarfwise. See COLLAR, GARTER, &c.

RIBBANDS, *Figured*. See FIGURED.

RIBBAND, or *Ribbon*, in *Heraldry*, is the eighth part of a bend. (See the article BEND.) It is borne a little cut off from the outlines of the escutcheon: thus; he beareth or, a ribband, gules.

RIBBANDS, from *rib* and *band*, in *Ship Building*, are long pieces of fir timber from four to eight inches square, according to the size of the ship; these are nailed on at certain heights to the frame timbers of the square body, as the *harpins*, which are oak of the same size, are nailed to the frames of the cant-bodies; but the latter are shaped to the form of the body by moulds and bevelling. The ends of the harpins forward are fastened against the stem, and those abaft against the stern-post or transoms; the ribbands then uniting with the harpins, envelop the ship lengthways, and being judiciously arranged, with regard to their distance from each other, they not only support the filling-timbers, but by being shored at every frame, the whole ship is supported, and kept to her true shape, until the plank is brought on, as they are in that case removed one at the time, the bottom being shored against the planks above. The difference between cant-ribbands and horizontal or square ribbands is, that the latter are only ideal, and used in the laying-off.

RIBBING NAILS. See NAIL.

RIBBLE, in *Geography*, a river of Lancashire, England, has its source in the high moors of Craven, Yorkshire, and passing the lofty mountains of Ingleborough and Pennigaut, enters the county of Lancaster near the town of Clitherhoe, where it forms a boundary to the county. Taking a south-western course, and receiving, in its progress through Lancashire, several smaller streams, and the tributary rivers of the Hodder, Calder, and Darwent, it passes by Ribchester and Preston. Soon after leaving the latter town it gradually expands its stream, and in a few miles presents a broad estuary, and unites its waters with the Irish sea. At this place, the ferry from North Theols to Lytham, it is about five miles across at high water. This river is navigable, for small crafters, as high as Preston, and was formerly capable of conveying vessels much higher up the country. At Preston it is crossed by an aqueduct, for the Lancaster canal. See Aiton's *Lancashire Gazetteer*, Beauties of England, vol. ix. and Whitaker's *History*, &c. of Whalley, 4to.

RIBBLING, in *Agriculture*, a term used in some districts to signify a mode of ploughing similar to that of slob-fur-

rowing. It is practised in some northern counties as well as those of the south, and in the former appears to be the only kind of winter fallow which is beneficial to lands of loose texture. Every furrow that is turned over on a foot of solid ground, from the beginning to the end of the ridge, that is every alternate furrow, is left untouched, and the ploughed furrow is turned over above it, so that the greatest surface possible is exposed to the ameliorating influence of the atmosphere, while, at the same time, the loose soil is out of the reach of any little rills which may run down in the different ruts. If the stubble has been, in some measure, luxuriant, and the ribbling done soon after the crop was taken from the ground, the two strata of stubbles meeting and fermenting under cover of the rid furrow, form, it is supposed, an aid to the subsequent manure, while the weeds are no less smothered than when the whole land is turned over by a complete ploughing. Nevertheless, it is believed, that when the use of green crops becomes general, and the planting and hoeing of them are neatly performed by the plough, this will stir the earth more perfectly, and pulverize and clean the soil more completely than any winter fallow or ribbling can possibly effect. See TILLAGE.

RIBCHESTER, in *Geography*, a village and parish in the hundred of Blackburn, and county palatine of Lancaster, England, is situated at the distance of five miles and a half N.N.W. from the town of Blackburn, and eight miles N.E. from Preston. Though now comparatively an insignificant place, it was in Roman times an important and flourishing town. Much dispute has taken place among antiquaries with respect to the original name of this station. Horsley calls it the *Coccium* of Antoninus, and Camden the *Rigodunum* of Ptolemy, the identity of which places is clearly proved by the reasonings of Dr. Whitaker, in his *History of Whalley*. (See COCCUM, in which article for *Rilcheſter* read *Rilcheſter*.) Mr. Whitaker, the author of the *History of Manchester*, however, contends that Ribchester must have been the *Vericonium* of Richard of Cirencester, and places *Coccium* at Blackrode. But whatever was the name of this place, it was indubitably among the number of *Agricola's* stations, and appears to have been not merely a military post, but the seat of manufacturing and commercial prosperity. At that period the river Ribble was navigable as high as *Coccium* to vessels of no inconsiderable burden. Of this fact, tradition, the vestiges of a dock, and numerous nautical relics, afford incontrovertible proof. To the filling up of the river, by the gradual accumulation of sand, is to be attributed, in part at least, the decay of this place after its abandonment by the Romans. Many votive stones, and others with inscriptions, have been found here. Of these Dr. Whitaker has printed nine, but they do not furnish any thing interesting either with respect to the place or the people. Various smaller antiquities have likewise been dug up here at different periods; such as silver and brass coins, an intaglio in a ruby, gold rings, &c. "But," to use the words of the historian of Whalley, "the noblest discovery ever made here, or perhaps in Britain, was in the year 1796, when the shelving bank of the Ribble exposed the following remains, which seemed to have been deposited in an excavation of the earth, filled up with soil of a different quality. These

were,

were, 1. A large flat earthen vessel, extremely thick, with the potter's stamp very distinct, "*Boriedof, Boriedi officina.*" 2. An entire patena of copper, about six inches diameter, with a handle. 3. The imperfect remains of a similar vessel. 4. A column, or colander of the same size and metal. 5. Several concave and circular plates of copper, with loops behind, which had evidently been intended to fasten them perpendicularly against a shaft, in order to form a Roman vexillum: such are frequent upon ancient monuments; but for a particular illustration, the reader is referred to a monument of Lucius Duceius, signifer of the ninth legion, in Hortley, pl. 63. 6. A very fine helmet, of which the crest was a sphinx, afterwards unfortunately lost, the head-piece enriched with basso-relievos of armed men skirmishing with swords, and a visor, consisting of an entire and beautiful female face, with orifices at the eyes, mouth, and nostrils." These remains were deposited in the museum of Charles Townley, esq. The helmet particularly merits attention. From the style of the head-piece, it is conjectured by the best judges not to be prior to the age of Severus; but the visor is a much more delicate and exquisite piece of workmanship, and is supposed not only to be Grecian, but, from the boldness of its lines, to belong to a period somewhat anterior to the last perfection of the arts in that wonderful country. For engraving of this helmet, with some observations thereon, see "*Vetusta Monumenta,*" vol. iv.

The chief remains of this station, now visible, are a mutilated rampart and fosse, surrounding a small eminence near the church, which is called Anchor-hill, from the circumstance of several anchors having been dug up at its base. In the same place, some years ago, an entire vessel was discovered at a great depth beneath the surface of the ground. From this place the Roman road, called Watling-street, stretches itself in a northern direction over Long Ridge Fell, marked by "a long stripe of green intersecting the brown heath of the mountain." Hence it is denominated Green Lane. It enters Yorkshire a little below Dowford bridge, and proceeds by Newton and Bentham to the celebrated station at Overborough.

The parish of Ribchester formerly constituted a portion of the original parish of Whalley, but was severed from it at the same time with that of Chipping. According to the parliamentary returns of 1811, it contained 649 houses, and 3544 inhabitants, including the townships of Ribchester, Dilworth, Dutton, Alton, and Hotherfal.

At Stede, in the vicinity of Ribchester, is a parochial chapel, which Dr. Whitaker states to be the oldest building within the boundaries of ancient Whalley. It appears to have formerly belonged to a guild, or hospital, and, from the style of its architecture, was probably erected in the reign of king Stephen. The arches are slightly pointed, and are decorated with zigzag, and other Saxon ornaments. In the interior is a "coffin tomb" of high antiquity, placed in front of the pulpit, which is elevated upon an antique stone pediment. The floor is covered with ancient grave stones, some of which are inscribed with Longobardic or Norman characters. An History of the original Parish of Whalley and Honor of Clitheroe, in the Counties of Lancaster and York, by Thomas Dunham Whitaker, L. L. D., F. S. A. 2d edit. 4to. Lond. 1806. A Description of the Country, from thirty to forty Miles round Manchester, by J. Aikin, M. D. 4to. Lond. 1795. History of Manchester, by John Whitaker, B. D., F. S. A. 2. vols. 4to. 1771. Antiquitates Bretonnenses; or the Roman Antiquities of Overborough, &c. Lond. 4to. 1746.

RIBECOURT, a town of France, in the department of the Oise, and chief place of a canton, in the district of

Compiègne. The place contains 520, and the canton 8805 inhabitants, on a territory of 182½ kilometres, in 21 communes.

RIBEMONT, a town of France, in the department of the Aisne, on the Oise, and chief place of a canton, in the district of St. Quentin; six miles S.E. of St. Quentin. The place contains 2345, and the canton 12,497 inhabitants, on a territory of 182½ kilometres, in 17 communes.

RIBENSKOI, a town of Russia, on the Tunguska; 72 miles E.S.E. of Eniseisk.

RIBERA, FRANCIS DE, in *Biography*, a learned Spanish Jesuit in the sixteenth century, was born in the year 1537. He pursued his academical studies at the university of Salamanca, and acquired a high reputation for his intimate acquaintance, not only with the Latin, but with the learned languages also. Having been ordained priest, he retired to his native place, that he might prosecute his theological studies in uninterrupted privacy, at the same time he was able to assist his brethren in the neighbouring country churches. In the year 1570, when he was thirty-three years of age, he was persuaded to unite himself with the disciples of Loyola, and become a member of their society. He now spent most of his time in interpreting the scriptures, and filling the chair of professor of divinity, in their seminary at Salamanca, till his death, which happened in the year 1591. He was author of numerous works, which are still in estimation with the Catholics; among these may be mentioned "*Commentarii in XII. Prophetas minores, sensum eorum et Prophetarum historicum et moralem, sæpe etiam Allegoricum complectentes,*" 4to. "*Commentarii Historici selecti in XII. Prophetas minores,*" 8vo. "*De Templo, et iis quæ ad Templum pertinent Lib. V.*" 8vo. And "*The Life of St. Theresa, Foundress of the reformed Order of the barefooted Carmelites,*" written in the Spanish language.

RIBERA, GIUSEPPE. See SPAGNOLETTO.

RIBERA, in *Geography*. See St. JAGO.

RIBERA de Muria, a town of Portugal, in Estramadura; six miles N. of Thomar.

RIBERAC, a town of France, and chief place of a district, in the department of the Dordogne; 17 miles E. of Perigueux. The place contains 2985, and the canton 11,194 inhabitants, on a territory of 85 kilometres, in 13 communes. N. lat. 45° 14'. E. long. 6° 25'.

RIBERAIRY, a town of Abyssinia; 25 miles E.N.E. of Axum.

RIBES, in *Botany*, an Arabian name, properly belonging to an acid-leaved species of RHEUM, see that article; but which botanists, for about 200 years past, have, by mistake, applied to the currant and gooseberry family, and with these it now remains. They constitute a natural and very important genus.—Linn. Gen. 111. Schreb. 154. Willd. Sp. Pl. v. 1. 1153. Mart. Mill. Dict. v. 4. Sm. Fl. Brit. 263. Prodr. Fl. Græc. Sibth. v. 1. 160. Ait. Hort. Kew. v. 2. 40. Pursh 163. Juss. 310. Lamarck Illustr. t. 146. (Grossularia; Tourn. t. 409. Gærtn. t. 28.)—Class and order, *Pentandria Monogynia*. Nat. Ord. *Pomacea*, Linn. *Cassi*, Juss.

Gen. Ch. *Cal.* Perianth superior, of one leaf, tubular, or bell-shaped; the limb cut, about half way down, into five oblong, concave, coloured, reflexed, permanent segments. *Cor.* Petals five, small, obtuse, erect, inserted into the rim of the calyx. *Stam.* Filaments five, awl-shaped, erect, inserted into the rim of the calyx; anthers incumbent, compressed, bursting at the edges. *Pist.* Germen roundish, inferior; style cloven; stigma obtuse. *Peric.* Berry globose, umbilicated, of one cell, with two lateral, opposite, longitudinal

## RIBES.

tudinal receptacles. *Seeds* numerous, roundish, slightly compressed.

*Eff. Ch.* Calyx superior, tubular, five-cleft. Petals inserted, with the stamens, into the calyx. Style cloven. Berry with many seeds.

The whole genus is shrubby. *Leaves* deciduous, alternate, stalked, simple, lobed and notched. *Flowers* stalked, generally pale, greenish or yellow, rarely reddish. *Fruit* eatable.

Section 1. Currants. *Stem without prickles.*

1. *R. rubrum*. Common Currant. Linn. Sp. Pl. 290. Willd. n. 1. Fl. Brit. n. 1. Engl. Bot. t. 1289. Woodv. Med. Bot. t. 74. Fl. Dan. t. 967. (*R. vulgaris*, fructu rubro; Ger. Em. 1593.)—Clusters smooth, pendulous. Flowers flattish. Petals inversely heart-shaped. Leaves obtusely five-lobed. Stem erect.—Native of woods and thickets, especially about the banks of rivers, in the north of Europe. Undoubtedly wild on the banks of the Tees, Durham. *Mr. Robson*. Commonly cultivated throughout the cooler parts of Europe, for the sake of its gratefully acid and wholesome berries, of which the white or bluish variety is the sweetest and mildest. It flowers in May; the fruit is scarcely ripe before August. The stem is bushy, three or four feet high, or more, if trained to a wall, with smooth blackish bark. *Leaves* on long stalks, spreading, doubly serrated, veiny, bright green, somewhat downy. *Flowers* in stalked, simple, pale green, drooping clusters. *Petals* yellowish-green. *Braçteas* ovate, minute, solitary at the base of each partial flower-stalk. *Fruit* quite pendulous.

2. *R. petraeum*. Rock Currant. Wulf. in Jacq. Misc. v. 2. 36. Jacq. Ic. Rar. t. 49. Willd. n. 2. Fl. Brit. n. 4. Engl. Bot. t. 705. (R. n. 818; Hall. Hist. v. 1. 364. *R. vulgaris rubro flore*; Clus. Hist. v. 1. 119.)—Clusters erect, somewhat hairy; pendulous when in fruit. Flowers flattish. Petals obtuse. Leaves acutely lobed. Braçteas shorter than the flower-stalks. Stem erect.—Native of Germany, Switzerland, and the north of England. This was confounded, even by Haller, with the former. The leaves are more downy, especially about the veins; more acutely lobed and notched. Clusters erect when in blossom; their stalks less elongated in the lower part. Flowers often stained with red. Berries bright red, very acid.

3. *R. spicatum*. Acid Mountain Currant. Robson Tr. of Linn. Soc. v. 3. 240. t. 21. Fl. Brit. n. 3. Ait. n. 6. Engl. Bot. t. 1290.—Spikes erect. Flowers nearly sessile. Petals oblong. Braçteas shorter than the calyx. Stem erect.—Native of the mountainous parts of Yorkshire and Durham, flowering in May. Differs from the last in having the inflorescence spiked, not racemose; upright both in flower and fruit. The berries are red and acid.

4. *R. procumbens*. Trailing Currant. Pall. Ross. v. 1. p. 2. 35. t. 65. Willd. n. 3. Ait. n. 3.—Clusters erect. Flowers flattish. Leaves bluntly lobed. Berries smooth. Stem procumbent. Plentiful, according to Pallas, on the mossy sides of hills in Dauria, where its fruit is much in request. The prostrate stems are concealed among the moss. Leaves not bigger than those of a gooseberry-bush, while the shrub is in blossom, but afterwards attaining the size and shape of the three foregoing species. Flowers like *R. rubrum*, but smaller, in erect clusters, which become drooping as the fruit ripens. The berries are full as large as a common Black Currant, but of a greenish-yellow, or, when quite ripe, reddish.

5. *R. glandulosum*. Glandulous Currant. Ait. n. 4. Willd. n. 4. (*R. prostratum*; L'Herit. Stirp. v. 1. 3. t. 2.

Pursh n. 4.)—Clusters erect, rough with glandular hairs. Flowers flattish. Leaves acutely lobed, toothed. Braçteas minute. Berries hispid. Stem creeping, with ascending branches.—Native of rocky moist places, in Newfoundland, Canada, and Pennsylvania, flowering in April and May. *Pursh*. Habit and leaves not unlike the last. The flowers are yellow, tinged with red. Berries red.

6. *R. rigidum*. Stiff-branched Currant. Michaux Boreal-Amer. v. 1. 110. Pursh n. 3.—Clusters lax, erect. Leaves acutely lobed and toothed, reticulated, rugose; downy beneath. Berries roughish. Branches straight.—On the banks of lake Mistassins, in Canada. *Michaux*. In the Pennsylvanian mountains, &c. flowering in May and June. Berries red, erect, as well as the flowers. *Pursh*.

7. *R. trifidum*. Notched-flowered Currant. Michaux Boreal-Amer. v. 1. 110. Pursh n. 2.—Clusters lax, downy. Leaves lobed, smooth; downy beneath. Flowers flattish. Segments of the calyx slightly three-cleft. Petals spatulate. Berries hairy.—Found by Michaux near Quebec, and at Hudson's Bay; by Pursh on the Pennsylvanian mountains, &c. flowering in April and May. Flowers like *R. rubrum*, but smaller. Calyx pale green. Petals purple, rounded, and blunt at the end. Berries red.

8. *R. albinerve*. White-veined Currant. Michaux Boreal-Amer. v. 1. 110. Pursh n. 1.—Clusters recurved. Berries smooth. Leaves short, acutely lobed, smoothish, with pale ribs.—Found by Michaux, about lake Mistassins, Canada; by Pursh, on the Catskill mountains, about New York, &c. flowering in April and May. Flowers small, greenish-yellow. Berries red.

9. *R. alpinum*. Tasteless Mountain Currant. Linn. Sp. Pl. 291. Willd. n. 5. Fl. Brit. n. 2. Engl. Bot. t. 704. Jacq. Austr. t. 47. Fl. Dan. t. 968.—Clusters erect. Braçteas longer than the flowers. Leaves smooth; shining at the back. Stem erect. Berries smooth.—Native of mountainous woods and thickets, in Germany, Switzerland, Sweden, Siberia, and the north of England, flowering in April and May. The leaves are rounder, and scarcely half so large as those of our common Currants, besides being quite smooth on both sides, and remarkably polished beneath. Braçteas very long, acute, erect. Flowers said to be often dioecious, from which cause perhaps the fruit is seldom perfected in our shrubberies, where this species often occurs. The berries are somewhat elliptical, of a beautiful red, but insipid and mucilaginous like a solution of gum arabic.

10. *R. resinosum*. Resinous Currant. Pursh n. 5. Curt. Mag. t. 1583.—Whole plant viscid, with glandular hairs. Leaves with roundish, notched lobes. Clusters erect. Flowers flattish. Braçteas tongue-shaped, concave, as long as the flowers. Berries hairy.—Gathered on the mountains of North America, by Mr. Frazer, from whose garden we obtained flowering specimens, in May 1810. This has more the aspect of a gooseberry-bush, especially in the size and form of the leaves, but the whole herbage is clothed with downy, viscid, foetid pubescence. Clusters most like those of *R. alpinum*, but the partial flower-stalks are extremely short, and the braçteas more obtuse, and elliptical. Flowers apparently dioecious, green, with short, rounded, yellowish petals.

11. *R. viscosissimum*. Glutinous Currant. Pursh n. 6.—Whole plant very glutinous, with viscid hairs. Leaves heart-shaped, bluntly three-lobed, serrated. Clusters short, erect. Calyx tubular. Petals oblong. Braçteas linear-spatulate, shorter than the partial flower-stalks. Germen hairy.—Found by the late governor Lewis, on rocky mountains in the interior of North America, flowering in

## RIBES.

June. Whole plant covered with viscous hair. *Flowers* large, yellow. This approaches near to *R. glandulosum*, Fl. Peruv. v. 3. 13. t. 233. f. b. It differs principally in the *leaves* being equally lobed, not having the middle lobe projecting; its long slender *partial flower-stalks*, and its *petals*. *Pursh*.

12. *R. sanguineum*. Crimson-flowered Currant. *Pursh* n. 7.—Leaves heart-shaped, three-lobed, serrated, veiny; smooth above; finely downy and hoary beneath. Clusters lax, downy, twice the length of the leaves. Calyx tubular. Petals oblong, equal to the limb. Bractæas obovate-spatulate, the length of the partial stalks. Germen hairy.—Gathered by governor Lewis, on the Columbia river, flowering in March. *Branches* purple. *Flowers* beautiful, blood-red or purple. It nearly approaches *R. albinervium*, Fl. Peruv. v. 3. 12. t. 232. f. b. *Pursh*.

13. *R. malvaceum*. Mallow-leaved Currant.—Leaves heart-shaped, slightly five-lobed, serrated, veiny; hispid on both sides; densely downy beneath. Clusters hairy, longer than the leaves. Calyx tubular, hairy. Petals rounded, not half so long as the limb. Bractæas ovate, acute, jagged, half the length of the calyx.—Gathered in California, by Mr. Menzies. *Branches* dark purple, downy, like every part of the plant. *Leaves* an inch, or inch and half, long; dark green above; white, and densely downy, beneath; hispid on both sides with glandular bristles. *Stipulas* beautifully fringed. *Clusters* dense, on long, rough, glandular stalks. *Calyx* red, about half an inch long, hairy, especially its base, and the *germen*. *Petals* wedge-shaped, rounded, somewhat cloven, scarcely one-third so long as the segments of the limb, which are elliptical. *Stamens* the length of the petals. Bractæas elegantly jagged and fringed. This fine species seems nearly allied to the last. We have not at hand the *Flora Peruviana*, to ascertain how far it resembles any in that work.

14. *R. aureum*. Golden-flowered Currant. *Pursh* n. 8.—Very smooth. Leaves with three, obtuse, sparingly notched lobes. Footstalks fringed at the base. Clusters dense. Calyx tubular, slender. Petals linear, half the length of the limb. Bractæas linear, equal to the partial stalks. Berry smooth.—Found by governor Lewis on the banks of the Missouri and Columbia, flowering in April. We received wild specimens from Mr. John Bradbury, three years ago. The *leaves* have the aspect of Hawthorn. *Flowers* in dense clusters. *Calyx* of a beautiful golden yellow, about three-fourths of an inch long, not unlike the flower of a Jonquill in miniature, and reported to have a similar scent; its segments oblong, obtuse. *Petals* purple. *Berries* red or brown, considerably larger than any garden currants, and peculiarly delicious in flavour. This very desirable plant is introduced into the gardens about London, but we have not yet heard of its blossoming.

15. *R. recurvatum*. Recurve-branched Currant. Michaux Boreal-Amer. v. 1. 109. *Pursh* n. 9.—“Branches recurved. Leaves dilated, downy, dotted with minute glands, acutely lobed. Clusters reflexed. Calyx tubular, smooth.”—Found near Hudson’s Bay. *Michaux*. *Berries* black. We know nothing more of this species.

16. *R. fragrans*. Fragrant Siberian Currant. “Pallas Nov. Act. Acad. Petrop. v. 10. 377. t. 9.” Willd. n. 6.—Stem ascending. Leaves bluntly three-lobed, glandular beneath.—Flowers bell-shaped. Clusters erect.—Native of Siberia, on mountains bordering on the country of the Mongols, where no woods grow. The *stems* are partly procumbent, a foot and a half long; their young *branches* besprinkled with yellow, prominent, glandular dots. *Leaves* on long stalks, smooth, serrated, slightly five-angled, with

three or five lobes; very veiny, and most glaucous beneath, where also they are covered with minute crowded drops of a yellow fragrant exudation, having a scent stronger than balm, approaching that of *R. nigrum*, n. 18, to which species indeed the present bears altogether a considerable resemblance. *Clusters* when in flower short, erect, rigid, dense, of about ten white, highly fragrant, *flowers*. *Calyx* bell-shaped, deeply five-cleft. *Petals* lanceolate, acute, spreading. Bractæas deciduous, smaller than in *R. procumbens*, n. 4. *Clusters* elongated in fruit, still erect, except when bent down by its weight. *Berries* reddish, extremely sweet, the full size of *R. rubrum*. Pallas.

17. *R. trifide*. Dark-coloured Siberian Currant. “Pallas Nov. Act. Acad. Petrop. v. 10. 378.” Willd. n. 7.—Root creeping. Stems erect, leafy in the upper part. Leaves five-lobed. Clusters smooth, pendulous. *Flowers* flattish. Petals revolute.—Native of lofty mountains in Siberia, towards Tartary. The creeping root throws up many erect *stems*, two or three feet high, bearing at their summits a few scattered *leaves*, resembling those of *R. rubrum*. *Clusters* always pendulous. *Flowers* reddish without, yellowish within. *Berries* small, black, insipid; their deep-red juice very useful for colouring wines. Pallas.

18. *R. nigrum*. Common Black Currant. Linn. Sp. Pl. 291. Willd. n. 8. Fl. Brit. n. 5. Engl. Bot. t. 1291. Woodv. Med. Bot. t. 75. Fl. Dan. t. 556. Lob. Ic. v. 2. 202.—Stem erect. Leaves five-lobed, acute. Clusters pendulous, downy, with a separate flower-stalk at their base. Calyx tubular-bell-shaped. *Berries* smooth.—Native of wet bushy islands, and banks of rivers, in Sweden, Germany, Switzerland, and England, flowering in May. In gardens it is well known, and valued for the fruit, whose flavour indeed, in a recent state, is not acceptable to every body; but its jelly is both agreeable, and useful for colds, sore-throats, &c.; whence this currant has been named Squinancy-berry or Quinsy-berry. The bush is of a more humble stature than *R. rubrum*; the *leaves* have a strong scent, if bruised, resembling Savine, and are somewhat glutinous when young. The tube of the *calyx* is more elongated than in any other British species. *Berries* large, black, each bunch always accompanied at the base by a solitary stalk, whose fruit is larger and earlier than the rest. Dr. Withering made the truly curious observation, that the *petals* are sometimes changed into *stamens*, of which we know no other instance.

19. *R. floridum*. Pennsylvania Black Currant. L’Herit. Stirp. v. 1. 4. Willd. n. 9. Ait. n. 8. *Pursh* n. 10. (*Ribesium nigrum pensylvanicum, floribus oblongis*; Dill. Elth. 324. t. 244. f. 315.)—Leaves three-lobed, cut; dotted with glands on both sides. Clusters pendulous, downy. Calyx somewhat cylindrical. Bractæas about as long as the germen.—Found in hedges and woods, from Canada to Virginia; flowering in April and May. *Flowers* pale yellow. *Berries* black. *Pursh*. The resinous dots on both sides of the *leaves* distinguish this species, and its *flowers* are more oblong than those of *nigrum*, with much larger bractæas.

SECT. 2. Gooseberries. *Stem* prickly.

20. *R. Diacantha*. Two-thorned Cluster Gooseberry. Pallas Reise v. 3. 722. t. I. f. 2. Rosl. v. 1. p. 2. 36. t. 66. Linn. Suppl. 157. Willd. n. 10. Ait. n. 9.—Prickles in pairs, in the place of stipulas. Leaves wedge-shaped, deeply three-cleft, bluntly notched. Clusters nearly erect. *Berries* smooth.—Native of gravelly, stony, saline soils in Dauria. Introduced into England by Mr. Buxh, in 1781. Hardy, flowering in May and June. Ait. Linnæus says it flowered every year at Upsal, without bearing fruit.

fruit. Possibly the *flowers* may be in some measure dioecious, like those of *R. alpinum*, a species which this nearly resembles, except the prickles.

21. *R. faxatile*. Rock Siberian Gooseberry. "Pallas Nov. Act. Acad. Petrop. v. 10. 376." Willd. n. 11.—Prickles scattered, setaceous. Leaves wedge-shaped, bluntly three-lobed. Clusters erect.—Native of granite mountains in Siberia. Allied to *R. alpinum* and *R. Diacantha*. Berries red, fourish, scarcely so big as our red currant. Pallas.

22. *R. reclinatum*. Procumbent Gooseberry. Linn. Sp. Pl. 291. Willd. n. 12. Ait. n. 10.—Prickles solitary or three together. Branches reclining. Stalks single-flowered, with a three-leaved bractea. Germen hairy.—Native of Germany and Switzerland. Said to have been long known in our gardens. It much resembles the following.

23. *R. Grossularia*. Rough Gooseberry. Linn. Sp. Pl. 291. Willd. n. 13. Ait. n. 11. Fl. Brit. n. 6. Engl. Bot. t. 1292. (*R. Uva crispa*; Fl. Dan. t. 546.)—Prickles solitary or three together. Branches spreading. Footstalks hairy. Stalks single-flowered, with a two-leaved bractea. Fruit hairy.—Common throughout Europe, but so generally cultivated, that we can hardly say when we meet with it truly wild. The *shrub* is bushy, of humble growth, armed, as every body knows, with smooth awl-shaped prickles, either solitary or ternate, in the place of *stipules*. Leaves bluntly three-lobed and cut, slightly downy. Flowers drooping, solitary, green, on downy stalks, with two separate bractea. Calyx cup-shaped. Germen and fruit rough with prominent bristly hairs. The berries are either green, yellow, or red.

24. *R. Uva crispa*. Smooth Gooseberry. Linn. Sp. Pl. 292. Willd. n. 14. Ait. n. 12. Fl. Brit. n. 7. Engl. Bot. t. 2057. Schmidel Ic. 5. t. 1. (*Uva crispa*; Fuchf. Hist. 187. Ger. Em. 1324.)—Prickles usually three together. Branches spreading. Footstalks hairy. Stalks single-flowered. Bractea united into a tube. Fruit smooth.—Native of Europe, and as commonly cultivated as the last, of which we believe it a mere variety. The number and connection of the bractea are certainly variable.

25. *R. aciculare*. Needle Siberian Gooseberry.—Prickles scattered, setaceous; those under the buds five together, combined. Leaves bluntly five-lobed and cut. Stalks single-flowered. Bractea united. Fruit smooth.—Gathered by Laxmann in Siberia. We find two specimens in the Linnean herbarium of this, which seems a very distinct species, hitherto neglected by every author. The habit is like the three last, but the branches are copiously armed all over with fine, straight, prominent, needle-like, brown prickles, besides the larger ones, five together, and combined by a broad base, which stand, like those of common Gooseberries, under the buds. Flowers solitary, drooping, on longish simple stalks, with two or three bractea, usually combined, about the middle. Calyx bell-shaped, smooth, red. Petals white, obovate, one-third the length of the limb. Germen smooth.

26. *R. ferax*. Strong-thorned Californian Gooseberry.—Prickles scattered, setaceous, very slender; those under the buds three together, combined, awl-shaped. Leaves five-lobed, rugose, downy beneath. Stalks single-flowered. Segments of the calyx lanceolate, twice the length of its tube. Germen and fruit prickly.—Gathered by Mr. Menzies, near Port Trinidad, in California. A very fine remarkable species, whose branches are thickly covered with tawny, setaceous, prominent prickles, about a quarter of an inch in length, and armed under each bud, with three

very strong and pungent awl-shaped ones, an inch long, having sometimes lesser reflexed prickles at their base. The leaves are not unlike our common Gooseberries, but more rugose; and densely downy at the back. Flower-stalks solitary, simple, longer than the leaves. Bractea scattered. Flowers drooping, large and handsome. Calyx three quarters of an inch long, funnel-shaped, downy and bristly; as far as we can judge from the dried specimens it seems of a fine crimson; its segments lanceolate, ribbed, erect, full twice as long as the tube. Petals half the length of these segments, erect, pale, obtuse. Stamens the length of the calyx. Anthers large, oblong-heart-shaped, pointed. Germen covered with prominent, glandular bristles, which harden, as the fruit advances, into stiff, sharp spines, so that whatever its flavour may be, it seems perfectly inaccessible, in the common way of eating gooseberries.

27. *R. rotundifolium*. Round-leaved Carolina Gooseberry. Michaux Boreal-Amer. v. 1. 110. Pursh n. 11.—Prickles solitary under the buds. Leaves nearly orbicular, slightly downy; lobes roundish, obtuse. Stalks single-flowered. Limb of the calyx tubular. Fruit smooth." Native of the high mountains of Carolina. Michaux.

28. *R. hirtellum*. Small-leaved Canada Gooseberry. Michaux Boreal-Amer. v. 1. 111. Pursh n. 12.—Prickles solitary under the buds, small. Branches somewhat hispid. Leaves three-cleft half way down, slightly notched. Stalks single-flowered. Fruit smooth.—Found among rocks, on the Allegany mountains; from Canada to Virginia, flowering in May and June. Pursh. Leaves small. Berries red.

29. *R. gracile*. Slender-stalked Blue Gooseberry. Michaux Boreal-Amer. v. 1. 111. Pursh n. 13.—Prickles solitary under the buds, very short. Leaves acutely lobed and cut, downy on both sides. Footstalks slender. Flower-stalks capillary, erect, mostly two-flowered. Calyx bell-shaped. Fruit smooth.—On rocks, and in mountain meadows, from New York to Carolina, flowering from April to June. Calyx smooth. Berries purple or blue, of an excellent taste. Pursh.

30. *R. flamineum*. Scarlet-flowered Californian Gooseberry.—Branches finely hispid. Prickles several under each bud, unequal. Leaves rounded, slightly three-lobed, smooth. Stalks two-flowered. Calyx hemispherical; limb in very long parallel segments. Petals equal to the limb. Stamens thrice as long.—Gathered by Mr. Menzies in California. Branches brown, clothed with copious, extremely fine, prominent, capillary bristles. Prickle under each bud rigid and sharp, about one-third of an inch long, with several smaller deflexed ones at the base. Leaves not an inch long, quite smooth, veiny; paler beneath; orbicular and entire, except three very slight, scarcely notched, obtuse lobes, at the extremity. Footstalks short, smooth. Flower-stalks longer than the leaves, hispid, glandular, two-flowered, with a single roundish bractea. Flowers scarlet. Calyx with a very short hemispherical tube, hispid like the germes; its limb five times as long, in five oblong, parallel, smooth segments. Petals of the same length, but rather paler and more obtuse. Stamens capillary, straight, parallel, projecting (four of them at least) with the style, full an inch out of the flower; the fifth is perhaps abortive. We know nothing of the fruit of this beautiful species, whose flowers have the aspect of a *Fuchsia*.

31. *R. triflorum*. Three-flowered Mountain Gooseberry Willd. Hort. Berol. v. 1. 61. t. 61. Pursh n. 14.—Prickles solitary under each bud. Leaves smooth, three or five-lobed, notched. Stalks about three-flowered. Petals spatulate, undulated. Style prominent, hairy, divided.

Fruit smooth.—On the Blue mountains; from Pennsylvania to Virginia, flowering in May and June. *Pursh*. The *partial flower-stalks* are very long. *Braçteas* very short. *Flowers* yellowish-green, with white *petals*. *Berries* pale red, small.

32. *R. oxyacanthoides*. Hawthorn-leaved Gooseberry. Linn. Sp. Pl. 291. Willd. n. 15. Ait. n. 13. Pursh n. 15. (*Grossularia oxyacanthæ foliis amplioribus, e linu Hudsonio*; Dill. Elth. 166. t. 139.)—Branches clothed with bristly prickles; those under the buds larger, mostly solitary. Leaves smooth, three-lobed, notched. Stalks one or two-flowered, shorter than the footstalks. Fruit smooth.—Native of rocky places at Hudson's Bay, Canada, New York, &c. flowering in April and May. It is said to have been cultivated in England in 1705, and was certainly in the Eltham garden near thirty years after. This resembles the common gooseberry in habit, but the *branches* are covered with innumerable, fine, bristly, not very rigid prickles, besides the larger ones, proper to this section of the genus, which are mostly solitary under each bud. *Leaves* larger, more deeply cut than in our gooseberries, smooth. *Flowers* drooping, one or two on each stalk. *Fruit* globose, the size of a black currant, purple, or almost black, with a cærulean bloom on the surface; slightly acid.

33. *R. lacustris*. Swamp Cluster Gooseberry. "Perf. Syn. v. 1. 252." Pursh n. 16. (*R. oxyacanthoides*; Michaux Boreal-Amer. v. 1. 111.)—Branches clothed with bristly prickles; those under the buds numerous, aggregate, pungent.—Leaves deeply lobed, doubly notched. Clusters downy, drooping, many-flowered. Fruit hispid.—Found in swamps, on the mountains, from Canada to Virginia, flowering from April to June. *Pursh*. Many persons have confounded this with the last, and we are not sure that the two are distinguished by our leading gardeners. We received specimens of the present from the Edinburgh garden, so long ago as 1782, with the name of *R. oxyacanthoides*. Another, in the herbarium of the younger Linnaeus, is marked *armatum*; an excellent name, given, we believe, by sir J. Banks or Dr. Solander, who could not overlook the characters which so clearly distinguish this from the true *oxyacanthoides*. These are not only the deeply divided vine-like *leaves*, but the numerous, combined, ascending *prickles*, almost palmate at their base, which stand under each leaf or bud; and also the long hairy glandular clusters of *flowers*, with a prickly *germen* and *fruit*. The *branches* are beset with abundance of rigid prickly bristles, rather stronger than those of *oxyacanthoides*. The *flowers* are of a dull, tawny, yellowish-green. "*Berries* amber-coloured, or brown." *Pursh*.

34. *R. cynosbati*. Thorny-fruited Cluster Gooseberry. Linn. Sp. Pl. 292. Willd. n. 16. Ait. n. 14. Pursh n. 17. Jacq. Hort. Vind. v. 2. t. 123.—Branches smooth. Prickles one or two under each bud, simple. Leaves five-lobed, downy beneath. Clusters drooping, of few flowers. Fruit armed with strong thorns.—On the sides of hills and rocks, in the Alleghany mountains, and in Canada, flowering from April to June. *Flowers* green. *Berries* dark brown, and covered with thorns. *Pursh*. Miller cultivated this species at Chelsea, where we believe it still remains. The *leaves* are downy on both sides, but especially beneath. *Prickles* mostly solitary, variable in size; those on the large globular fruit are peculiarly strong.

We have thus more than doubled Willdenow's catalogue of species, in this genus. Some of the newly discovered ones, from North America, are likely to prove great acquisitions to our kitchen gardens, provided they bear fruit in this climate; of which, till the experiment is fairly made, there must always be some uncertainty.

RIBES, in *Gardening*, contains plants of the hardy, deciduous, shrubby kind, of which the species cultivated are; the common currant (*R. rubrum*); the common black currant (*R. nigrum*); the rough-fruited gooseberry (*R. grossularia*); the smooth-fruited gooseberry (*R. uva crispa*); the procumbent gooseberry (*R. reclinatum*); the hawthorn-leaved currant (*R. oxyacanthoides*); and the prickly-fruited currant (*R. cynosbati*).

It is observed by Martyn, that the first sort is very apt to be infested with the aphid ribes, in which case the green leaves become red, pitted, and puckered. It has been long cultivated in the garden, and greatly improved. There are several varieties; as the common sort, with small red fruit; with white fruit; with pale fruit, commonly called the Champaign currant, differing only in being a pale red or flesh-colour. But since the white and red Dutch currants have been introduced and become common, the old sorts have been almost banished, and are now rarely to be found. And Mr. Forsyth mentions the fine new white Dutch, long-branched red, striped-leaved red-white currant, and large pale and red Dutch.

There are also the sweet currant, the small-fruited currant, and a variety with blotched leaves, which is kept in some plantations; but as the variegation is apt to go off when the plant is vigorous, it scarcely deserves a place in them.

Of the second there is a sort often termed the American black currant. The berries have a very peculiar flavour, which many persons dislike; but are commonly eaten in puddings in some parts, and make a tart little inferior to the cranberry. The juice of which is also frequently boiled down to an extract, with the addition of a small proportion of sugar; in this state it is called rob, and used in sore throats and other diseases.

Currants in general are by some supposed the most useful of all the small fruits, as serving either for table or culinary uses, as well as for wine, and continuing long in succession with due management. The black sort is seldom sent to table as a fruit for that purpose. But it is a sort which may be infused in spirit of any kind, in which way they make a good liquor.

The third, or rough-fruited, sort is a low branching shrub, which has the berries pendulous and hairy. And it is observed by the editor of Miller's Dictionary, that if the roughness do not distinguish this from the following, the roughness or smoothness of the berries will hardly do it, as Mr. Robson has found that seeds from the same plant will produce both rough and smooth fruit. He cannot regard them as different species.

The fourth, or smooth-fruited, sort has the berry pulpy, subdiaphanous, pale, amber-coloured, red or purple, smooth, and the pulp watery and sweet. And Martyn remarks, that the gooseberry seems to have been formerly a fruit in very little esteem, but has received so much improvement, that it is now become valuable, not only for tarts, pies, and sauces, both fresh and preserved in bottles, but as an early desert fruit, and preserved in sugar for winter use to answer the same purpose.

It may be noticed, that the most important varieties of the red kind are, the hairy, smooth, deep red, damson or dark red, blueish, red raspberry, early black-red, Champaigne, &c. Of the green kind; the hairy, smooth, Gascoigne, raspberry, &c. Of the yellow kind; the great oval, great amber, hairy amber, early amber, large tawny or great mogul, &c. And of the white kind; the common, white-veined, and large crystal. But besides these, there is the rumbullion, large ironmonger, smooth ironmonger, hairy globe, and innumerable

# RIBES.

innumerable others, some of very large size, annually raised from seed, weighing from ten to fifteen pennyweights; however, there are small ones better tasted. There are said to be upwards of two hundred, at least in name.

And Mr. Forsyth has given the following list from the catalogue of Messrs. Kirk, nurserymen, at Brompton, near London.

The supreme red, perfection red, high sheriff of Lancashire, royal George, unicorn, rough amber, white walnut, Ackerley's double bearer, royal oak, Miss Bold's, sparkler, Ackerley's Rodney, Hampson's Cæsar, Monk's Charles Fox, St. John, pigeon egg, Worthinglowe's conqueror, golden eagle, Royder's triumph, Williamson's yellow hornet, Swingham, Jackson's golden orange, Goliath champion, hairy amber, Nixon's golden eagle, Worthington's white lily, Laylord's seedling, Nixon's white heart, Riding's old England, Bakeley's Swingham, Tillotson's St. John.

The same writer also adds another list of the largest new sorts which were shewn in Lancashire, in the summer of 1800, with their colour and weight, as communicated by Messrs. McNiven, nurserymen, Manchester.

## Red Sorts of Gooseberries.

	dwt.	gr.
Alcock's king	16	15
----- duke of York	16	1
Boardman's royal oak	15	4
Brundrit's atlas	17	1
Chapman's peerless	15	21
Dien's glory of England	16	2
Fairlow's lord Hood	14	5
Fisher's conqueror	17	19
Fox's jolly smoker	15	8
Hall's porcupine	13	20
Lomax's victory	16	11
Mason's Hercules	13	16
Taylor's volunteer	16	17
Worthington's glory of Eccles	14	10

## Yellow Sorts of Gooseberries.

Read's satisfaction	15	4
Robinson's stump	13	21
Smith's green mask	13	20
Yates's duke of Bedford	14	11

## White Sorts of Gooseberries.

Adam's snow-ball	12	22
Atkinson's white hall	14	8

Chapman's Highland white	12	0
Davenport's lady	15	0
Gibson's Apollo	14	20
Holding's white muslin	13	0
Kenyon's white noble	13	6
Moor's white bear	14	12
Woodward's white smith	17	2

It is observed, that in favourable seasons, many of the above sorts have been known to weigh more by several pennyweights.

In all the south-eastern parts of Lancashire there are a great number of little societies held by the labouring and manufacturing workmen, and the gardeners; where these sorts of fruits are annually exhibited, under many different arbitrary names and designations, as *Goliaths*, *golden drops*, &c. and their merits and capabilities of improvement finally settled and decided upon.

The fifth sort has the fruit when ripe commonly dark purple, but sometimes red or even yellow.

In the sixth kind the fruit is small and round, the size and shape of a currant; the colour at first purple, but when ripe, dark purple with a blue bloom; it is smooth, on a short slender stalk.

*Method of Culture in the Currant Kind.*—In general these may be raised with great facility from layers, seed, cuttings, and in other ways. In the first of these modes, when the trees are cut low, Mr. Forsyth advises the laying down some of the branches either in the winter or spring seasons, when the ground in the quarters or rows is dug, which should always be done annually. In the autumn following, these layers will have made fine roots; then they may be taken off, and planted out where they are to stand, and they will mostly bear fine fruit in the following summer.

But in the second method, the cuttings should be chosen of the strongest and straightest shoots, which should be cut six or eight inches in length, and be planted out on an east or north border, in the early autumn, at the distance of a foot from row to row, leaving only a few inches out of the ground. In this way they may be kept perfectly free from weeds. In dry weather, during the spring, they should be often refreshed with water. Some also raise these plants from suckers; but this is a method that should be avoided as much as possible, as they never grow handsome, and are apt to throw out suckers afterwards.

With respect to the seed, it should be sown on a border where the mould is fine, either in the autumn or early in the spring; and the young plants, when they appear, be kept free from weeds. When they have attained sufficient growth, they may either be planted out where they are to remain, or be set out in nursery-rows. However, Mr. Forsyth observes, that under the bushes that have been covered for late fruit, plenty of self-sown plants may constantly be found, which he advises to be planted out by themselves. And those who make currant-wine may, he thinks, save the seed, after the fruit is squeezed, and dry it: it may then be sown in the manner directed above, by which, most probably, some fine varieties may be obtained. As in many gardens there still remains, the same writer remarks, a small sort of red and white currant not worth cultivating, he would advise those who have any of them to root them up, and plant in their room the large red and white Dutch, the long-bunched red, and Champagne large pale red. These kinds of plants may be planted out, it is suggested, either in the quarters, or single rows round the edges of the quarters, in the gardens or other places. And he would particularly

particula-ly recommend planting a few againll a fourth or west wall, or paling, which will produce fruit much earlier than in the quarters, &c.: also to plant some between other fruit-trees, on north walls, or palings, for later crops. These may be covered with double nets, to preserve them from birds; tucking in a few fern branches between the two nets, which will prevent the heat of the sun and drying winds from shrivelling the fruit. In the quarters they should be covered with mats, for the same purpose; at the same time permitting all the leaves to remain on the bushes, to shade the fruit, and make it keep the longer in a proper state.

In what respects the pruning of the bushes, the work may, according to the above author, be begun in the month of November, and continued till March, as it suits the planter's convenience. And they should never be left too thick of wood; but a great deal depends on the management of them in summer, to have strong and fine wood for the following season. If they have been neglected for some years, and suffered to run up to long naked wood, they must, in his opinion, be cut down near the ground: they will then send forth fine strong shoots. In this case, he would recommend heading down every other tree, and cutting the others partially, by taking out every other branch as near as can be to the ground, unless they are trained up with single stems; in which case, it will be necessary to cut them as near as possible to where the branches begin to break out and form the head. And in the winter pruning, the strongest and finest shoots should be preserved, leaving them from nine to eighteen inches long, according to their strength, and from eight to ten inches apart, and as regular as possible from top to bottom of the tree; taking care to cut out all the dead and weak shoots. And particular attention should be paid in summer, keeping the middle of the bush open to admit the sun and air; preserving the finest and strongest shoots that are nearest the stem. Some, he remarks, are fond of training them up with single stems, to a considerable height, to form fine round heads, which are very ornamental, if not suffered to run up too high; as, in that case, they are liable to be broken by the wind, if not well supported by stakes. Care must be taken not to let the shoots run to more than six inches long, because such short shoots will not be so liable to be damaged by the wind as long and weak ones are, especially when loaded with fruit. He prefers dwarfs from three to four feet high.

Further it is added, that the same manner of pruning, &c. will do for black currants; but as they grow stronger than the red or white, the shoots should be left thinner, and laid in longer, which will make them produce larger and finer fruit. And those against walls and palings should have the shoots laid in thinner than those in the quarters, and trained as horizontally as possible; shortening them, in the winter pruning, to a foot or eighteen inches, according to the strength of the shoots.

As this sort of fruit is very liable to be devoured by earwigs, which take shelter under their leaves and branches, bundles of bean-stalks should, he suggests, be hung up some time before the bushes are covered with mats or nets. If proper attention be not paid to this, the fruit will generally suffer very much from these insects. After the bushes are covered, take the mats off once in three or four days, and kill the earwigs that have got in the bean-stalks, which it will be necessary still to keep hung up. As there is a sweetness in the inside of bean-stalks, which attracts the earwigs, they very readily take shelter in them from rain. By proper attention to these directions, these destructive insects may be kept under, and the greater part of the fruit be

preserved. It is also necessary to carefully stock up all suckers at the roots of the trees, and keep them as clean as possible; otherwise they will prevent the sun and air from penetrating to the roots, and greatly weaken and injure the trees.

These plants are very liable to be infested with aphides, and other insects, from which they should be freed as soon as possible, by proper picking, washing, and liming.

*Culture in the Gooseberry Kind.*—All these are capable of being raised by cuttings and layers, as well as seeds for new varieties. They are likewise sometimes increased by suckers; but this last is not an advisable method, as the plants raised in this way are more apt to throw out suckers than those from cuttings or feed. The cuttings should be made from the strongest and cleanest shoots, and have the length of seven or eight inches, being planted out in the early autumn, in a border which has an eastern or northern aspect, at the distance of about a foot from row to row, and having only about three or four inches of each cutting above the ground; as by this means they may be kept clean by hoeing. They require to be frequently watered in the spring season, when the weather is dry.

Also the layers may be laid down any time in the autumn or spring season, in the common way, when they readily strike root; and in the following autumn, may be taken off, and planted out where they are to remain, or in nursery-rows, to get strength to be finally planted out.

And the seed obtained from the ripened berries should be sown in the autumn, or very early spring, in a bed of fine light mould. The plants come up readily, and should be kept perfectly clear from weeds; and when they have had one or two years' growth, may be removed into nursery-rows, in the same manner as the currants, to remain till they become fit for being planted out. In this way good new varieties may be procured. Mr. Forsyth remarks, that the gardeners in the vicinity of Manchester have made great additions to the varieties of this fruit; and by mixing up a rich soil to plant them in, carefully watering, shading, and thinning the fruit, have brought the berries to a size much larger than had been before met with in this country; but that those of some of the layers are much thicker in the skin, and not so well flavoured as many of the old sorts.

In most parts of Lancashire, this is indeed a kind of fruit which is uncommonly fine, and of a very large size, in both the red and white kinds; and in many of the southern and south-eastern parts, very great attention, in numerous instances, is bestowed in the cultivation and improvement of it, so as to render it of an unusual magnitude and fine appearance. This is chiefly effected by much more pruning and thinning than that which is generally had recourse to with these sorts of plants, frequent digging about them, and a very liberal use of well rotted stable dung incorporated with the mould which is applied near their roots.

As to the methods of planting out this sort of plants, they are extremely various. According to Mr. Forsyth, the market gardeners in the vicinity of the metropolis set them out in rows from eight to ten feet apart, and six from plant to plant. In cases of this sort, he recommends that they should be pruned in the autumn, as about the beginning of October, when the ground between them may be planted with coleworts, or beans for a spring crop; and by so doing, there will be no occasion to tread over the ground, and hurt the coleworts, in pruning the bushes; as, before the gooseberries begin to shoot, the coleworts will be all cleared off the ground. And after this time, (or before, if you find it convenient,) a good coat of rotten dung should

be laid on the ground; then dig it, and plant early potatoes, but not so near as to hurt the gooseberries by their growth. He likewise advises that the roots of gooseberries should be kept clear to admit the sun and air. In small gardens, he would recommend planting them in a quarter by themselves, at the distance of six feet between the rows, and four feet from plant to plant: they may be planted round the edges of the quarters, about three feet from the path; in which case, the ground will be clear for cropping, and a man, by setting one foot on the border, can gather the gooseberries, without injuring the crop that may be on the border. Also that, as they like a rich soil, they should be dunged every year, or at least have a good coat of dung once in two years. They should never be planted under the shade of other trees, as it injures the flavour of the fruit.

And in respect to the pruning of the bushes, it is a practice too common, Mr. Forfyth thinks, to let them branch out with great naked stems, suffering them to remain in that state for years. When that is the case, they should be cut down near to the ground in the winter pruning, as it will make them throw out fine strong healthy shoots, which will bear fruit the second year; and as gooseberry bushes, in general, bear their fruit on the second year's wood, great care should be taken in summer to keep the middle of the bush clear, to admit a free air, leaving the finest and strongest shoots from six to ten inches distant from each other. This will, he conceives, help to ripen and harden the wood. It is a practice with some to shorten the shoots in the autumn or winter pruning, which should be always near to a wood-bud; which may be known by its being single, whereas fruit-buds are in clusters. The shoots may, he thinks, be shortened to eight or ten inches, according to their strength. Some leave them at full length for three or four years, thinning out those that are superfluous. He advises always to leave a proper number to be trained up between the full length shoots, to succeed them when they are tired of bearing; and then to cut the old ones down to the young ones that are to succeed them. By these means, the bushes may always be kept in a constant state of bearing. Those branches which were cut the first year will, in the second, throw out short dugs, or spurs, which produce the fruit; and these should by no means be cut off, unless the branches are in a sickly state, and require to be cut close down, when the bushes are overloaded with fruit. It will then, in his opinion, be necessary to cut out a good deal of the old wood, to assist nature to recover herself, after producing so great a quantity of fruit.

He likewise advises that great attention be paid to the cultivation of the early and late sorts. In some old gardens, in particular, there are, he observes, very valuable sorts that have been of late too much neglected; he would therefore recommend to those who live in the neighbourhood of such gardens, to observe their time of ripening, and to cultivate those especially which are early and late. And he adds, that it is a practice with some to clip the tops of gooseberries with a pair of garden shears, as they would clip a thorn hedge; this he by no means approves of, as the fruit will not be half the size, nor of so fine a flavour, as when the bushes are kept clear of such wood as is unnecessary.

Further it is recommended that great care should be taken in spring and summer to flock, or grub up, all the suckers from the roots of the bushes, leaving their stems clear and unencumbered. And as many of the Lancashire sorts are apt to grow horizontally, and the branches frequently trail on the ground, which renders them liable to be broken by high winds, especially when they are loaded with fruit, he would recommend two or three hoops to be put round them, to

which the branches may be tied, to support them, and prevent their being broken by the wind, or any other means.

In cases where it is wished to have them late, they should be planted on north walls and palings, between the other trees, when they may be removed as the trees begin to meet. If laid in thin, they will bear very fine and handsome fruit. He would advise to plant the finest late sort; as by this method the table will be supplied much longer than by the common custom of planting in quarters of the garden.

Also immediately after pruning, he always applies the plaster composition to the ends of the shoots and cuttings; and he finds it of great use in preventing the exhalation of the sap, and preserving the cuttings till they take root, and become established.

It may be observed that these sorts of plants are very much infested with a small green caterpillar, which frequently devour both leaves and fruit: great attention is of course necessary to observe their first appearance on the bushes; as, if not destroyed early, they increase so fast, that they soon devour all the leaves, and the fruit is good for nothing. It is noticed, that they first appear generally on the edges and under-sides of the leaves. In order to destroy them, he advises to take some sifted quick-lime and lay it under the bushes; but not at first to let any of it touch the branches or leaves; then shake each bush suddenly and smartly, and the caterpillars will fall into the lime; if the bush be not shaken suddenly, the caterpillars, on being a little disturbed, will take so firm a hold as not easily to be shaken off. After this is done, some of the lime should be sifted over the bushes; this will drive down those which have lodged on the branches. The caterpillars ought, in his opinion, to be swept up next day, and the bushes well washed with clear lime-water mixed with urine; this will destroy any caterpillars that may still remain, and also the aphides, if there are any on the bushes at the time.

*Forcing.*—It may be stated, that sometimes trees of the gooseberry and currant kinds are forced for early fruiting, by means of artificial heat in fruit-forcing-houses, hot-walls, or forcing-frames, &c. For this purpose, some young trees should be planted in largish pots, one plant in each, and being advanced to a full state of growth for plentiful bearing, should be introduced in any of the above forcing departments that are in work by fire, or hot-bed heat, or both, in forwarding any principal sorts of fruit-trees, plants, or flowers, at the proper season, as about January or February, in which the same culture, in regard to the degree of heat, and other requisites, necessary for the other trees, &c. is suitable for these. Water should be given occasionally to the earth in the pots, and sometimes after the fruit is set, throwing it lightly over the branches on a warm sunny day; and they will thus produce ripe fruit in April or the following month.

However, the forcing of this sort of fruit is now seldom much attended to, in consequence of other finer sorts being so common.

*RIBES*, in the *Materia Medica*. The *ribes rubrum* or *rutilum*, i. e. the red currant, and the *ribes album*, or white currant, are varieties of the same species, and therefore the fruit of both, considered in both a botanical and medical sense, is perfectly analogous. The red currant is abundantly cultivated in our gardens, from which we are supplied with the fruit; and this, on account of its grateful acidity, is universally acceptable, both in its natural state, and as variously prepared by art with the addition of sugar. The juice is a most agreeable acid in punch. If equal weights of picked currants and pure sugar are put over the fire, the liquor

liquor that separates spontaneously is a molt agreeable jelly. The juice of red currants, with sugar, is a common beverage at Paris, where it is generally preferred to orgeat or lemonade. Dr. Cullen classifies this fruit with the alimentary plants, and being generally and exclusively considered as such, it was not received in the British catalogues of the *Materia Medica* till that published in a late collection of the London Pharmacopœia: but it is omitted in the last edition. The medicinal qualities of red currants appear to be similar to those of the other subacid fruits, which are esteemed to be moderately refrigerant, antiseptic, attenuant, and aperient. Hoffman and Boerhaave had great confidence in the efficacy of these fruits in obstinate visceral obstructions. They may be used with considerable advantage to allay thirst in most febrile complaints; to lessen an increased secretion of bile; and to correct a putrid and scorbutic state of the fluids, especially in sanguine temperaments; but in constitutions of a contrary kind they are apt to occasion flatulency and indigestion.

The *ribes nigrum*, or black currant, has berries larger than those of the red; and besides possessing the properties in common with the "fructus acido-dulces," they are also said to be peculiarly useful in sore throats; and to manifest a diuretic power in a very considerable degree. In cases of inflammatory angina, they may be advantageously employed to answer the same intentions as gargles, and from their efficacy in this respect they have acquired the name of "Squinancy berries," but the proofs of their diuretic powers seem to want confirmation. With respect to their former application and utility we may observe, that the black currant jelly in common domestic use is rendered less efficacious by having too much sugar in its preparation. The fruit both of this, and of the red currant, afford a pleasant wine; and that made of the former is mentioned by Haller, "ex eo optimum vinum fieri non deterius vinis verioribus viteis, quando annuum est." The leaves of the black currant are extremely fragrant, and have been recommended for their medicinal virtue, which Bergius states to be "mundificans, pellens, diuretica." An infusion of these leaves is said to have the taste of green tea, and when prepared from the young leaves, is to some people very agreeable. The official preparations of the black currant berries in the late London Pharmacopœia (but omitted in the last edition) were the "Syrupus ribis nigri," and the "Succus ribis nigri inspissatus." Woodv. Med. Bot. See CURRANTS.

RIBIERS, in *Geography*, a town of France, in the department of the Higher Alps, and chief place of a canton, in the district of Gap; four miles N.W. of Sisteron. The place contains 1301, and the canton 3939 inhabitants, on a territory of 180 kilometres, in nine communes.

RIBNA, a town of Russia, in the government of Kholivan, on a river of the same name; 112 miles S.E. of Krasnoiarsk.

RIBNIK, a town of Silesia, in the principality of Ratibor; 13 miles E. of Ratibor. N. lat.  $50^{\circ} 3'$ . E. long.  $18^{\circ} 30'$ .—Also, a town of European Turkey, in Walachia, on the Alaut; 44 miles S. of Hermanstadt. N. lat.  $45^{\circ} 19'$ . E. long.  $24^{\circ} 8'$ .—Also, a town of European Turkey, in Walachia, on the Ribnik, otherwise Rymnick, as it is called by the Russians; the see of a Greek bishop. From a severe battle fought here in 1789, between the Austrians and Russians against the Turks, Suwarrow, who commanded the Russians, and defeated them, was created by the emperor Leopold, a count of the empire, invested with the order of St. Andrew, and honoured with the title of Rymnicki by the empress Catharine; 100 miles S. of Jassi. N. lat.  $45^{\circ} 36'$ . E. long.  $27^{\circ} 4'$ .—Also, a river of Walachia, which

runs into the Siret, near Dubravitzza, on the borders of Moldavia.

RIBNITZ, a town of the duchy of Mecklenburg, situated on a large lake, near the mouth of the Reckenitz; 12 miles N.N.E. of Rostock. N. lat.  $54^{\circ} 17'$ . E. long.  $12^{\circ} 35'$ .

RIBNITZY, a town of Poland, in the palatinate of Braclaw; 64 miles S. of Braclaw.

RIBNO, a town of Prussia, in the province of Oberland; 15 miles N.N.E. of Ortelburg.

RIBNOI, a town of Rullia, in the government of Jaroslavl; 40 miles W.N.W. of Jaroslavl. N. lat.  $57^{\circ} 45'$ . E. long.  $39^{\circ} 14'$ .

RIBS, in *Anatomy*, the bones forming the sides of the chest, attached to the spine behind, and terminating in front in portions of cartilage, some of which are fixed to the sternum, the others not. The former are called *true*, the latter *false* ribs. They are described in the article LUNG of this Cyclopædia.

RIBS, *Fractures of the*, in *Surgery*. See FRACTURE.

RIBS of *Fish*. There is a very great variety in the shape and other peculiarities of the ribs of fish. They are in some smooth, and flattened sideways, as in the cyprini; in others they are rounded, as in the cotti and gadi. In the cyprini the several species have from thirteen to nineteen ribs on a side, and the vertebræ are from thirty-seven to forty-nine in number, differing greatly in number in the several species of the same genus. The ribs in many fish adhere to the vertebræ, by means of cartilages, and seem only continued parts of them; but in others they are free and loose, and do not so much as touch the vertebræ. We find instances of the first sort of structure in the cyprini, salmon, &c. and of the other in the perch, the gadi, and the pleuronectæ. In the spinose fishes, the last vertebra always is terminated by a pair of broad apophyses placed perpendicularly, and touching one another, and by means of cartilages these are fixed to the bones of the tail. Artedi Ichthyolog. See *Anatomy of FISH*.

RIBS, a figurative expression for the timbers or frames of a ship, arising from the comparison of it with the human body, as the keel with its keelson, to the back-bone, and the timbers to the ribs; for the former unite and support the whole fabric, since the stem and stern-frame, which are raised on the ends of the keel, may be said to be a continuation of it, and serve to connect and inclose the extremities by the hawse-pieces forward, and the transoms abaft, as the keel forms and unites the bottom by the floor-timbers. The idea, if carried further, may in a manner represent the muscular parts of the human fabric; for the wales, clamps, and thickitts, at the different heads of the timbers, are as so many muscles or strong ligaments to connect the ribs together, while the planking of the bottom and top-sides, which is thinner, may be compared to the skin or covering of the whole; and hence planking is often termed, *skimming* the ship.

RIBS of a *Parrel*, short flat pieces of wood hollowed on the back, having a hole near each end, through which the parrel rope is reeved. See PARREL.

RIBS, among *Jewellers*, the lines or ridges which distinguish the several parts of the work, both of brilliants and roses.

RIB-WORT, in *Botany*. See PLANTAIN.

RICA, among the Romans, a veil with which the ladies covered their heads.

RICÆ, *ῥίξες*, surgical bandages for the head.

RICARD, DOMINIC, in *Biography*, was born at Toulouse in 1741, and entered into the congregation of the

Christian doctrine, and became a distinguished professor in it. He quitted the society after some years, and took up his residence at Paris, where he employed himself in instructing youth, and in literary pursuits. He was celebrated for his deep knowledge in the Greek language, and engaged in the great task of translating the whole works of Plutarch. Between the years 1783 and 1795 he published his version of that philosopher's moral works, in 17 vols. 12mo. : of the Lives he only published 4 vols. 12mo. He published likewise a poem, entitled "La Sphere," in eight cantos, 8vo. 1796, which contains a system of astronomy and geography, enriched with notes, and notices of Greek, Latin, and French poems, treating on astronomical subjects. Ricard died in 1803. He was distinguished by modest merit, and the practice of all the social virtues.

**RICAUT, Sir PAUL**, was the youngest son of Sir Peter Ricaut, knight, supposed to be a merchant in London. The time and place of the birth and education of the subject of this article are not known, but he appears to have travelled during several years in Europe, Asia, and Africa. In the year 1661 he went out as secretary to the earl of Winchelsea, the ambassador extraordinary to the Ottoman Porte. Here he remained eight years in that post. In 1663 he published the treaty or capitulation concluded between Charles II. and the Turkish sultan, in which was the favourable article, that English ships should be exempted from search for foreign goods. When his connection with the Porte was expired, he was appointed English consul at Smyrna, an office which he held about eleven years, to the entire satisfaction of the Turkey company, and with the respect and attachment of all the Europeans in that city. Upon his return, he employed himself in literary occupations till the year 1685, when he accompanied the earl of Clarendon, lord-lieutenant of Ireland, as his secretary for Leinster and Connaught. He was nominated by James II. one of his privy-council for Ireland, and judge of the admiralty court, and received the honour of knighthood. After the revolution, he was sent by King William as his resident to the Hanse towns, in which post he continued ten years. He died in England, in the year 1700, literally worn out with age and long services. Independently of his high character as a diplomatist, he was celebrated for his knowledge of the learned languages, and also of the modern Greek, the Turkish, the Italian, Spanish, and French. As an author, he is known by "The present State of the Ottoman Empire;" "The present State of the Greek and Armenian Churches;" "A Continuation of Knolles' History of the Turks." He continued "Platina's Lives of the Popes" to his own time. He translated from the Spanish, "The Royal Commentaries of Peru, by Garcilasso de la Vega." A paper of this author is inserted in the Transactions of the Royal Society, of which society he was a member. Biog. Brit.

**RICCATI, VINCENT**, a learned Italian Jesuit, was born at Castell-Franco, in the territory of Treviso, about the year 1707. His genius inclining him chiefly to the study of the mathematical sciences, he cultivated them with so much success, that his superiors selected him as a proper person to teach them to others. He accordingly was chosen professor in the college at Bologna, which he filled with reputation till the suppression of the order in 1773. He died in 1775, leaving behind him several works that testify his high merit as a scholar, among which is "A Treatise on the Integral Calculus," in 3 vols. 4to. He did not confine himself to the abstract mathematics, but paid much attention to the study of hydraulics; a branch of science of the utmost importance in all the northern Italian states, where the

many and rapid rivers expose the country to continual inundations. In this line he appears to have rendered considerable service to the Venetian territories; so much so, that in 1774 a gold medal was struck in his honour.

**RICCI, BARTHOLEMEW**, a learned Italian, was born at Lugo, in Romagna, in the year 1490. He studied under Amaseo in Bologna, and for further improvement visited Padua and Venice. He passed some years in the house of Giovanni Cornaro, as preceptor to his son, who was afterwards a cardinal; and for some time kept a school at Ravenna. Through the recommendation of Calcaquini, he was invited, in 1539, to the court of duke Hercules II. of Ferrara, to undertake the education of the princes Alfonso and Luigi. He there acquired the affection of his pupils, and the esteem of the learned. He died at the age of 79, in the year 1569. The principal works of Ricci are "Orations," and "Epistles," the Latin style of which has been much applauded, as a happy imitation of that of Cicero. The most laborious of his works is entitled "Apparatus Latine Locutionis," being a Latin lexicon, in two parts; the first containing the verbs, and the second the nouns with which they are joined. It was printed at Venice in 1535. Ricci also wrote a comedy in Italian prose, entitled "Le Balie," which is well spoken of; and some Italian poems, which have appeared in collections.

**RICCI, MATTHEW**, an eminent missionary, was born of a good family at Macerata, in 1552. He was sent to study the law at Rome, where, at the age of 19, he entered into the society of Jesuits. He had not completed his theological studies, when he followed to the East Indies his preceptor, father Valignan. During his abode at Goa, he applied assiduously to the language of China, to which country he was destined. In 1583 he arrived at Caoquin, in the province of Canton, where he settled with some brethren. To ingratiate himself with the Chinese, he made a map of the world, in which, whilst he corrected their prejudices with respect to the relative dimensions of their country, he complied with them by altering the meridian, so as to place it in the centre. It was not till 1600 that he was able to gain access to the emperor at Peking, employing the pretext of bringing him a present of curiosities from Europe. He was well received, and permitted to settle in that capital, where his mathematical skill rendered him acceptable to the court and men of letters. He purchased a house there, and built a church; and the progress, such as it was, which Christianity made in the metropolis of China, was greatly owing to his exertions. He died there in 1610, leaving curious memoirs on China, of which father Trigault made use in his work "De Christiana Expeditione apud Sinas."

**RICCI, MICHAEL-ANGELO**, an Italian cardinal, and able mathematician, in the 17th century, was descended from a noble family originally from Bergamo, and born at Rome in the year 1619. In the course of his studies, he conceived a powerful inclination for the mathematics, which was confirmed by Torricelli, during the temporary residence of that philosopher at Rome. Under his directions, Ricci's genius was carefully cultivated, and his progress reflected great honour both on the tutor and pupil. After Torricelli left Rome, he maintained a regular correspondence with Ricci, who proved and illustrated in a happy manner several of his new theorems. In the year 1666 Ricci published a little work, entitled "Exercitatio Geometrica," &c. in which he determined, in a purely geometrical manner, the tangents, and the maxima and minima of curves, chiefly compared with conic sections of the first order. This piece was reprinted by the Royal Society of London, as a treatise of

the greatest utility; and it was warmly applauded by some of the most distinguished mathematicians of the age. Having been induced to enter into the church, he relinquished his mathematical pursuits, and wholly devoted his attention to the assiduous study of divinity, and the duties of his new profession. He filled several ecclesiastical stations, and, among others, those of secretary to the congregation of indulgences and of relics, and of confessor of the holy office. In the year 1681, pope Innocent XI. raised him to the purple; an honour which he wished to decline, but was compelled to accept by the pontiff's absolute command. He possessed it, however, only for a short period, as he died in 1682, at the age of 64. One of his "Dissertations" is preserved in cardinal Brancaccio's "Works;" another in Charles Dati's "Epistola ad Philalethos;" and one of his "Letters" in the first volume of the collection, entitled "Lettere Memorabili." Gen. Biog.

RICCI, SEBASTIAN, was born at Belluno, near Treviso, in 1659; and having discovered an early genius for painting, was conducted by his father to Venice, and placed as a disciple with Fred. Cervelli, a Milanese artist of good reputation, with whom he studied for nine years. He afterwards improved his practice at Bologna, &c. by copying, and obtained the favour and patronage of Rannuccio, the second duke of Parma.

By the liberality of that prince, he was honourably maintained at Rome, studying the productions of the best ancient and modern masters; and there he formed that manner which distinguishes his productions, and exhibits a ready and splendid invention, a free and masterly handling of the pencil, with a full luxuriance of colour, which for a while raised him into the highest esteem, and consequently immense employment.

Having quitted Rome, he returned to Venice, where he was so eagerly solicited for his paintings, that he had scarcely time to take even necessary refreshment. His fame spread through Europe, and he received an invitation to the court of the emperor at Vienna, to adorn the magnificent palace of Schoenbrunn. From thence he was encouraged to visit London, where he was immediately and incessantly employed by the court, the nobility, and persons of fortune. Here he remained ten years, with his nephew and co-adjutor, Marco Ricci, who painted skilfully scenes of architecture and landscape. He acquired great wealth by the immense occupation he found; and then returned to Venice, where he passed the remainder of his days till his 75th year, when he shared the common fate of mortals.

Ricci was one of the few, comparatively speaking, who enjoy during their lives the utmost extent of their fame. In his history, that portion of renown which attaches to him died with him, or nearly so. In fact, he was a machinist, one who, being conversant in the rules of art, and skilful in the application of the means, dazzled where he could not instruct, and deluded by ingenuity without judgment, and art without expression. His works are to be found in many of our great houses, as well as those of his nephew. At Chelsea and at the British Museum there are considerable pictures of his painting, but they do not rise in esteem by continued observation; and yet, unfortunately, they had sufficient influence in their day to lead the artists astray from the contemplation and imitation of the works of Raphael, and the greater masters of the Italian school.

RICCIA, in *Botany*, a cryptogamic genus of plants, named by Micheli after a Florentine Senator of his time, Peter Francis Riccio, President of the Order of St. Stephen, Auditor of the Academy of Pisa, &c.; who seems to have been rather a patron, than a practical cultivator, of

botanic science.—Mich. Gen. 106. t. 57. Linn. Gen. 566. Schreb. 766. Mart. Mill. Dict. v. 4. Schmidel. Ic. t. 44. 45. Hedw. Theor. 116. t. 29. Juss. 8. Lamarck Illustr. t. 877.—Class and order, *Cryptogamia Hepatica*. Nat. Ord. *Alga*, Linn. *Hepatica*, Juss.

Ess. Ch. Male, scattered warts?

Female, German globose, sunk, with the *style*, in the frond. *Capsule* exposed, globose, crowned with the *style*, of one cell. *Seeds* numerous, elliptical.

The genuine species of this genus grow on the earth, flourishing in the damp cold season of the year, and disappearing in hot dry weather. Hence they are supposed to be annual. Such are three of the British species; *R. glauca*. Linn. Sp. Pl. 1605. Engl. Bot. t. 2546; *R. minima*. Linn. Sp. Pl. 1605. Mich. Gen. t. 57. f. 6; and *R. crystallina*. Linn. Sp. Pl. 1605. Dickf. H. Sicc. fasc. 15. 20. Mich. Gen. t. 57. f. 3.—These form small glaucous patches on the ground, in sandy or moist places. The other two British species float in fresh water pools; *R. fluitans*. Linn. Sp. Pl. 1606. Engl. Bot. t. 251, whose frond is forked and linear; and *R. natans*. Linn. Syst. Nat. ed. 12. v. 2. 708. Engl. Bot. t. 252, whose inversely heart-shaped form, with copious linear serrated scales, like radicles, beneath, has a very peculiar appearance. Nothing is known respecting the fructification of these two last. *R. fruticulosa* of Dickson is a *Jungermannia*, Engl. Bot. t. 2514, probably a variety of the *furcata*.

RICCIA, *La*, in *Geography*, a town of Italy, in the Campagna di Roma; 1 mile S.E. of Albano.

RICCIA, a town of Naples, in the Molise; 15 miles E. of Boiano.

RICCIARELLI, in *Biography*. See VOLTERRA, DANIEL DA.

RICCIOLI, JOHN-BAPTIST, a learned Italian Jesuit, and an eminent philosopher, astronomer, and mathematician, in the 17th century, was born at Ferrara, a city belonging to the papal jurisdiction, in the year 1598. At the age of 16 he commenced his novitiate in the society of Jesus. When he had completed his course of academical studies, he was selected to teach successively rhetoric, polite learning, philosophy, and scholastic divinity, in the Jesuits' colleges at Parma and Bologna. While he discharged the duties of these appointments with great success and reputation, he devoted his leisure hours to the study of geography, hydrography, chronology, experimental philosophy, and astronomy. During the dispute which took place in his time, respecting the correctness of the Gregorian reformation of the calendar, he insisted himself among the advocates for the reform, and published some little pieces on the subject at Bologna, under the name of Michael Manfredi. His principal attention, however, was occupied on productions of greater magnitude. He projected a grand work, which was to be divided into three parts, containing a complete system of philosophical, mathematical, and astronomical knowledge. The first of these parts was given by him to the public in 1651, in two large and closely printed volumes, folio, under the title of "Almagestum Novum, Astronomiam Veterum, Novamque Complectens," &c. In imitation of the "Almagest" of Ptolemy, it presents us with a collection of the discoveries and improvements in astronomical science, from the earliest ages of antiquity to the author's own time. From a table of contents which is prefixed to this part, it appears that the second part was to be divided into five books, treating of trigonometry, or the doctrine of plane and spherical triangles, astronomical instruments, the optical part of astronomy, geography, and chronology; and the third part into ten books, comprehending

hending observations of the sun, of the moon, of eclipses, of the fixed stars, and planets, with precepts, and tables of the primary and secondary motions, and other altronomical tables. But if these parts were completed, they do not appear to have been ever published. In the year 1661 he presented to the world his "Geographiæ et Hydrographiæ Reformata, Libri XII." in folio; and in 1665, his "Astronomiæ Reformata, Tomi duo," folio, 2 vols. in one. The last work which he published made its appearance in 1669, under the title of "Chronologia Reformata, et ad Certas, Conclusiones Redacta," folio, 2 vols. in one. Father Riccioli died in 1671, when about 73 years of age.

**RICCOBONI, Louis**, a comic actor and writer, born at Modena in 1674, devoted himself to the theatre under the name of Lelio. In 1716 he came to France with his family, and distinguished himself as the best actor at the Theatre Italien. Religious motives induced him to quit the stage in 1729; and he died in 1753, much esteemed for the decency of his manners, and his amiable disposition. He was the author of a number of comedies, which had a temporary success, and which contain much comic humour. One of them, entitled "Les Coquets," was revived a few years since. He also wrote "Penfées sur la Declamation;" "Discours sur la Reformation du Theatre;" "Observations sur la Comedie et sur le Genie de Moliere;" "Reflexions Historiques et Critiques sur les Theatres de l'Europe;" and "Histoire du Theatre Italien."

The "History of the Italian Theatre" of this author, in 2 vols. 8vo., published in 1730 and 1731, and the "Reflections Historical and Critical upon all the Theatres of Europe," which appeared in 1738, contain many judicious observations relative to the stage in general, and, in the work first mentioned, to the lyric theatre in particular.

**RICCOBONI, MARIE LABORAS DE MEZIERES**, second wife of the preceding, was born at Paris in 1714. After her marriage, she became an actress on the Italian theatre, which she quitted with her husband. She is known by several novels, written with much elegance of style and refinement of sentiment. The principal of these are "Lettres de Miladi Catsby;" "Lettres de la Comtesse de Sancerre;" "Lettres de Sophie de Valiere;" "Ernestine;" "Lettres de Milford Rivers." She also translated Fielding's *Amelia*; and she appears to have had a predilection for England, in which the scene of several of her novels is laid. She was in habits of intimate correspondence with Garrick. The works of Madame Riccoboni were printed collectively in 10 vols. 12mo. Neufchâtel, and 9 vols. 12mo. Paris. They rank among the most elegant and ingenious of the class, and display much knowledge of the tender affections, and great decency joined to vivacity. Several of her novels have been translated into English. She died in 1792, reduced by the troubles of the time to a state approaching to want.

**RICE**, in *Botany*. See *ORYZA*.

**RICE**, in *Rural Economy*, the name of a plant cultivated in many parts of the East, in South Carolina, in America, and also in Spain, Italy, and Piedmont. It is a plant that grows to the height of about two feet and a half, with a stalk not unlike that of wheat, but fuller of joints, and with leaves resembling that of the leek. It branches out into several stems, at the top of which the grain grows in clusters, and each of them is terminated with an ear or beard, and inclosed in a yellow rough hulk. When stripped of this, they appear to be of an oval shape, of a shining white colour, and almost transparent. It is probably a plant that cannot be cultivated in this climate, as the experiments said to be made by sir Joseph Banks, and detailed as below by a writer in the tenth volume of the *Agricultural Magazine*,

seem to shew. It is stated, that the dry or mountain rice which he received last year from the Board of Agriculture for trial, had been procured at a considerable expence by sir John Murray, from the neighbourhood of Serinagur, a city in India, situated at the foot of mount Imaus, where snow lies till late in the spring; and where the climate has been supposed to resemble that of England sufficiently to make it probable that the vegetable productions of the one would equally succeed in the other country; he therefore considers it as a duty owing to the patriotic exertions of sir John, to give the Board some account of the result of the trial of it, made at Spring-Grove, near Hounslow, in Middlesex. He adds, that it was not till near the end of May, when the samples, being of six sorts, were delivered out by the Board, and they were sown immediately, on the 21st day of that month, on six small beds in a garden, under the shelter of a paled fence, in a south exposure. And the grains were sown very thin, in order that the progress of their vegetation might be better noted: in a very few days they appeared above ground. The season being warm, with a moderate supply of rain, it was seldom necessary to water them; however, when they appeared to flag, which generally happened after three or four dry days had taken place, they were well sprinkled with a watering pot. He says, that in less than a month they had grown several inches high; each sort had acquired an appearance very different from the rest; some were pale green, and had broader blades; some were deeper coloured, and narrower in the blade; and one sort had a brown hue on the whole plant; and the bases of the leaves in this kind were nearly black.

He further states, that during the month of August, they tillowed much more than he has observed any other corn to do; so much so, that although they had been sown very thin, they became a dense, compact bed of plants: the blades in some of the kinds standing as close, or closer to each other, than the thickest sown barley ever does. At the close of the month the blades were from a foot to eighteen inches high; the plants continued to tillow, each root having by this time produced from ten to twenty off-sets, but no symptom of a rising stem was at all observable. In the middle of September they had still continued to tillow, and the blades to strengthen, so that some of them were at least two feet long. As the frosts of the autumn were now nearly approaching, it became an object of some importance to examine the state in which the plants really were, in order to ascertain the probability of their having produced ears, or possibility of their having ripened corn, if they had been sown a month or two earlier.

The most careful inspection was therefore made by dissection, but no traces could be found of the rudiment of a joint beginning to form itself on the crown of the root, or of the embryo of the glumes of the ear, which in all kinds of corn are first discernible in that part. He says that about this period he was taken ill, and obliged to desist from observing their future progress; but a frost soon after followed, which cut the blade down to the earth, and at once destroyed all hopes of these kinds of rice producing grain in our climate; the quantity of the blade was however so uncommonly great, that it is not impossible, he thinks, it might be advantageous to sow it as food for cattle, for a very large proportion of stock might certainly be maintained upon an acre of it. He concludes by observing, that before the frost sets in, he had ordered a tuft of each kind of the rice to be transplanted into a pot, and placed in a hot-house, in order, if possible, to ascertain the natural period of this grain; whether, like winter corn, it requires eight or nine months to come to perfection, or, like our Lent

corn, arrives at the same period in five or six : but all of these died, notwithstanding great attention was paid to them : some seed, however, which he had given to Mr. Lambert, succeeded better ; it was sown in his hot-house in the month of June, where it thrived well, but did not produce ears till near Christmas, a period of seven months, from whence it is probable, the grain would have ripened in less than two months from the time the ear appeared. It is easy to deduce that in the neighbourhood of Serinagur these kinds of rice are either sown as winter corn, or the climate there is far better suited to promote the quick progress of vegetation than our's is. It was, when it produced ears, about three feet and a half high, and some of the stems had five joints, including the radical one : had it been in a more suitable climate, it would certainly have grown taller, for the flowers dropped off without producing seed.

It is however cultivated much in the East, as in China, as well as in the southern parts of America ; the method of which is thus described by Mr. Duhamel.

1. To hasten the sprouting of the rice, it is put into baskets, and soaked for some days in a standing water.
2. When their rice-grounds are so soaked with water as to be quite like mud, they are ploughed with a buffalo yoked to a plough very simple in its make, having but one share, one handle, and no wheels.
3. After a gentle rain, they break the clods with a kind of large hurdle, drawn by a large buffalo ; the driver sitting upon it to increase the weight.
4. The ground is cleared of all stones, and whatever roots are in it are pulled up by a strong harrow, with great iron teeth. This instrument is drawn by a buffalo, and a man guides it by the help of two handles, like those of a plough, upon which he leans hard. The earth is like mud, and partly covered with water during all this operation.
5. The earth is afterwards smoothed with a harrow, which has several rows of teeth. A man guides this harrow by its two handles, whilst a buffalo draws it ; and as fast as its teeth form little channels in the ground, the water runs in and fills them up.
6. When the rice that was laid to soak has sprouted, the seed is known to be good ; and it is then sown by hand, very thick, and as equally as possible. Only part of the ground is sown in this manner, to furnish plants for the rest. The day after it has been sown the points of the plants appear above the surface of the water ; for the ground is overflowed all this time with just enough water to cover it. And it is added, that when the plants have acquired a little strength, they are sprinkled with lime-water, to destroy the insects, and some of the weeds that would hurt them. For this purpose a small basket is fastened to the end of a long handle, and dipped in the lime-water, which runs through it, and is conveyed over the plants. And the Chinese have a great veneration for the first inventor of this method, which answers to our custom of steeping wheat in lime-water, or manuring land with quick-lime.
7. Towards April, when the plants are grown strong enough to cover the whole field, and look very green and even, the greatest part of them is pulled up by handfuls, all the mud is carefully washed off their roots, and, being held at the same time as even as possible with one another, they are planted in tufts, pretty far asunder, and in a quincunx form, in fields prepared on purpose for them. A serene day is chosen for this operation, which must be performed as quick as possible. This practice of the Chinese is, he thinks, with respect to the common culture of rice, what the new husbandry is with respect to the common culture of wheat.
8. The rice must be watered, which is always done in China by overflowing it. To this end, the rice-grounds are always near a rivulet, pond, or great pool of

water, from which they are separated only by a bank or caufeway. If the water was higher than the rice-ground, a trench cut through the caufeway would overflow it at once : but as it is generally lower, or on a level with the rice-ground, the necessary quantity is conveyed in pails or buckets, which are worked chiefly by the help of ropes. 9. Though a man cannot step in these rice-grounds without being up to his knees, the Chinese weed them three times in a summer, and that with such care, that they pull up even the roots of every weed. 10. When the rice is ripe, which is known by its turning yellow, like wheat, it is cut down with a sickle, made into sheaves, and carried into a barn, where it is threshed with flails pretty much like ours : the straw is removed with pitch-forks and shovels, and the outer husk of the grain is taken off by beating it with great wooden pestles, or a kind of mallet, after which it is sifted and winnowed : and, lastly, to get off the under husk, the grain is put between two mill-stones, which are worked by a lever fastened to the upper one. But the two most remarkable circumstances of this culture are, 1st, the care which the Chinese take not to let their plants be too close together, lest they should rob one another of their food ; and 2dly, their weeding their rice-grounds three times in a summer, which answers the end of the hoeings recommended for the alleys between the beds of other grain, cultivated according to the horse-hoeing husbandry.

This plant is said to have been lately cultivated with success near Dumfries, by Mr. Charters ; notwithstanding the want of success in the above trial, as well as by others in Cambridgeshire. And it is not improbable, but that by degrees it may be so naturalized to the climate, as has been the case with many other plants, as to be cultivated without much trouble or difficulty, and thus contribute to the advantage of the country as an article of the grain kind. Rice forms an excellent kind of bread when incorporated with flour, as well as a good food for the feeding of different sorts of animals of the poultry and other kinds.

Rice is much used as food in the Roman Catholic countries in time of Lent. The ordinary preparation is, by first steeping it in water, then boiling it in milk. Some make it into a sort of farina, or flour, by pounding it in a mortar, after having first put it in hot water, and again washed it out in cold.

Among the common kinds of grain, rice is accounted the mildest and most nutritious, and is supposed to be particularly serviceable in dysenteries and diarrhoeas. It is less viscous than wheat, or of less tenacity, when boiled with water.

The northern nations eat their fowls and other meats with rice and saffron. The Chinese make a wine of rice, which is of an amber colour, and tastes like Spanish wine, and serves them for their common drink. In some parts of Europe they also draw a very strong brandy, or spirit, from rice.

*RICE-Balking*, in *Agriculture*, a provincial word applied to a method of ploughing, in which, according to Mr. Marshall, the flag is always turned up towards the unploughed ground, the edge of the coulter passing close to the edge of the flag last turned : whereas, in *Job-furrowing*, the flag is turned towards the ploughed ground, the coulter passing fifteen or sixteen inches from the last ploughed furrow ; into which, in this case, the edge of the flag hangs ; and, in both cases, a slip of unploughed soil, of a width nearly to that of the flag, is buried.

*RICE-Bird*, in *Ornithology*. See *EMBERIZA Oryzivora*.

*RICE Lake*, in *Geography*, a lake of Canada, having a portage

portage of 11 miles to lake Ontario. It discharges itself by the river Trent, into the head of the bay of Quinté.

**RICEBOROUGH**, a town of America, in Liberty county, Georgia, where the county courts are held. The county contains 6228 inhabitants.

**RICERCARE**, Ital. to seek; whence *ricercata*, a research, a flourish, a prelude, an impromptu, a voluntary. See **RESEARCH**.

**RICEYS, LES**, in *Geography*, a town of France, in the department of the Aube, and chief place of a canton, in the district of Bar-sur-Seine; 6, 7, and 8 miles S. of Bar-sur-Seine. The place contains 3842, and the canton 7875 inhabitants, on a territory of 167½ kilometres, in 8 communes.

**RICH, CAPE**, a cape on the west side of Newfoundland, towards the north end, and is the N.E. part of the gulf of St. Lawrence, having the isle of St. John, and some other small isles, to the N. This cape was the boundary of the French privilege of fishing, which extended from hence northward, and round to cape Bonavista.

**RICH Inlet**, a narrow channel between two small islands near the coast of North Carolina. N. lat. 34° 14'. W. long. 77° 52'.

**RICHARD of St. Victor**, in *Biography*, a celebrated divine and scripture commentator in the 12th century, was a native of Scotland, who went to pursue his studies at the university of Paris. Here he entered among the canons regular of St. Augustine, at the abbey of St. Victor, and became a pupil of the famous Hugh, who, like him, derived his surname from the same house. Under this master he assiduously studied the several branches of science, as far as they were then known, particularly theological and biblical literature; and he acquired great reputation by his proficiency, as well as the friendship of the most eminent men in that seat of learning. In 1164 he was elected prior of his monastery, where he died, in the year 1173, equally respected for his virtues as for his learned attainments. His critical pieces are very accurate for the time in which he lived. His style, however, is not very elevated; on which account his pious treatises, though abounding in excellent matter, are greatly deficient in weight and energy. His works consist of critical observations and remarks on some of the historical parts of the Old Testament, relating to the tabernacle and the temple of Solomon; allegorical and moral "Commentaries" on several of the Psalms, the Song of Songs, and the Apocalypse; questions on certain difficult passages of St. Paul's epistles, and other parts of the bible; and numerous critical, doctrinal, and practical treatises. The whole have been frequently printed in a collective form; and the best edition is said to be that of Rouen, in 1650, in 2 vols. folio.

**RICHARD I.**, king of England, surnamed *Cour de Lion*, son of Henry II. by Eleanor Guienne, was born in the year 1157. As second son he was invested in the duchy of Guienne, and county of Poitou. In 1173 he united with his brothers, Henry and Geoffrey, in a rebellion against his father, which was soon quelled, and forgiven by the reigning monarch. Richard was now sent to Poitou to reduce some revolted barons, where he displayed that martial spirit for which he was afterwards celebrated, and on account of which he obtained his surname. Refusing to pay homage for the duchy of Aquitaine to his elder brother Henry, a war broke out between them in France, which their father found great difficulty in terminating. Henry soon after this died, and Richard, being now heir apparent, was required to resign Aquitaine to his youngest brother, John. This he refused, and new wars ensued. In 1189 he joined

Philip Augustus, king of France, against his own father, and did homage to the French king for the possessions which he held on the continent. A war was the consequence of this unnatural junction, in which Henry was harried and worn out by Richard, while he found himself abandoned by his youngest son John. Henry died in July of the same year, and was succeeded in his throne by the subject of this article. He is said to have visited his father's corpse on the day after his decease, and expressing great remorse for his past behaviour, charged himself with being his murderer. Richard was crowned at Westminster, received into his confidence the faithful servants of the late king, and discountenanced all those who had been abettors in his own rebellion. He set at liberty his mother, queen Eleanor, who had long been in a state of confinement, and endeavoured to conciliate the affection of his brother John by grants of great extent in England and France. Richard, while prince, had taken the cross along with his father; and now he had come to the crown, he was determined to give scope to his martial talents in the East. Having made the requisite preparations, he, in 1190, had an interview with Philip of France, who had also taken the cross, at which, mutual conditions were agreed upon respecting their co-operation in the expedition, and the peace of the kingdoms during their absence. As a prelude to their enterprise, which, according to the opinion of the times, was regarded as extremely pious in its object and motives, Richard and his nobles, who had embarked in the same cause, exercised their zeal in a horrible massacre and pillage of the Jews in several of the principal towns, which was ended by a bonfire of the bonds which the Christians had entered into with this much injured people.

About the middle of the year, the kings of England and France mustered their forces, which amounted to 100,000 men in arms, in the plains of Vefelay, on the borders of Burgundy. Richard then proceeded to Marseilles for embarkation, and in September the two monarchs met at Messina, where they spent the winter, in the course of which, dissensions arose that were nearly breaking out into open hostilities, but which ended in a new treaty, in which all differences were for the present adjusted. Richard had long been under engagements to marry Adela, Philip's sister; but an attachment which he had formed to Berengaria, daughter of Sanchez, king of Navarre, together with some misconduct of the French princess, induced him to break the contract, in which it appears that Philip acquiesced. Eleanor arrived at Messina with Berengaria; but Richard, without waiting to celebrate his nuptials, set sail in April, 1191, with his fleet, which was soon dispersed by a storm. The king sailed into Crete; but three of his ships, with his intended bride, and his sister, the queen of Sicily, on board, were stranded on the coast of Cyprus. The king of that island treated the unfortunate crews and the princesses with great rigour, in revenge for which insult, Richard landed his army in the island, defeated the inhabitants in two battles, and reduced the king to the surrender of himself, his only daughter, and his sovereignty. In this island he consummated his marriage with Berengaria, and then embarked for Palestine.

The siege of Acre, celebrated likewise in modern times, which had been commenced two years before, was still carrying on by the relics of the emperor Frederic's army, with the other Christian adventurers who had at different times joined the banners of the cross, while it was obstinately defended by a numerous Saracen garrison, supported by Saladin at the head of a powerful host in the field. The arrival of the two kings infused new vigour

into the besiegers, and feats of arms were performed under the walls, by Richard and Philip, especially by the former, who far surpassed his rival in military enterprise. The city surrendered in July 1191, and immediately there were two competitors for the titular kingdom of Jerusalem, whose claims were espoused by the rival kings. Philip, however, did not remain long in the East; he returned home, leaving 10,000 men with Richard, who marched from Acre with the intent of reducing the other towns on the sea-coast, while Saladin attended his motions, and gave him frequent assaults, which produced deeds of extraordinary valour on both sides, till at length a general engagement was brought on, in which, after both wings of the Christian army had been defeated, Richard in the centre, by the most heroic exertions of bravery, and consummate military skill, gained a complete victory. This was immediately followed by the possession of Joppa, Ascalon, and other places which Saladin had deserted; and Richard advanced within sight of the holy city; but the greater part of the allies refused to concur in the siege of that capital, and he was obliged reluctantly to return to Ascalon. Here he concluded a truce with Saladin, on the condition that Acre, Joppa, and the other sea-ports of Palestine, should remain in the hands of the Christians, and that they should enjoy full liberty to perform their pilgrimages to Jerusalem.

Richard now prepared to return home, where his presence was absolutely necessary on account of the great disorders into which his kingdom was fallen. Previous to his embarkation, he terminated the contest for the crown of Jerusalem, by concurring in the election of Conrad, and bestowing the conquered kingdom of Cyprus upon the disappointed competitor Lusignan. At this period, Conrad was murdered in the streets of Tyre by two emissaries of the prince of Assassins, commonly called the "old man of the mountain;" and although the deed was clearly traced to this source, Philip was base enough to calumniate Richard as the author of it, in order that he might have an excuse for the designs which he was carrying on against him in Europe.

Richard set sail from Acre in October, 1192. In the course of his voyage he was wrecked near Aquileia: thence he pursued his way through Germany, in the disguise of a pilgrim; but being discovered near Vienna, he was arrested by the orders of Leopold, duke of Austria, and thrown into prison. He was afterwards given up to the emperor Henry VI., who had been offended by him. When intelligence of this event reached England, queen Eleanor wrote repeatedly to the pope, representing to his holiness the scandal and injustice of felling and imprisoning the most illustrious champion of Christendom, whose exertions for the common cause were celebrated throughout Europe and Asia; and claiming, in behalf of the captive king, the protection of the holy see. Her representations were of no avail: Richard was kept in prison, and loaded with irons; which afforded his rival, Philip, full opportunity for invading his dominions. He entered into a treaty with John, who readily took up arms against his brother's government, while Philip was making himself master of great part of Normandy. Richard, in the mean time, supported his misfortunes and indignities with the most undaunted courage. The emperor, to justify his own conduct, produced the royal captive before the diet at Worms, under a charge of several heinous offences; but Richard repelled the accusations with so much spirit and eloquence, that he carried the assembly with him, who loudly exclaimed against his detention. At length he was liberated, on the condition that 50,000 marks should be paid as a ransom. He arrived in

England in March, 1194, to the great joy of his subjects in general.

When Philip was made acquainted with Richard's deliverance, he wrote to John "to take care of himself, the devil being broke loose." The property of John was immediately confiscated, and his castle at Nottingham seized. Richard was recrowned at Westminster, in the presence of William, king of Scotland; and he then began to raise money, that he might take revenge upon his inveterate foe, Philip of France. John threw himself at the feet of his brother, imploring, in the most abject terms, his pardon. "I forgive him," said the hero, "and hope I shall as easily forget his injuries as he will my pardon." In the ensuing war between Richard and Philip, the former gained some advantages; but a truce suspended farther hostilities. A peace was terminated in 1196; but in the following year, the war was renewed, in which much cruelty was exercised on both sides.

England, during this foreign contention, had been the scene of much calamity, partly through disturbances occasioned by the exactions of a needy and rapacious government, and partly by the more grievous calamities of famine and pestilence. A lasting accommodation with France, as preparatory to another expedition to the Holy Land, was in agitation, when the reign and life of Richard were brought to a close through his avarice, which is thus related by Hume.

Vidomar, viscount of Limoges, a vassal of the king's, had found a treasure, of which he sent a part to that prince as a present. Richard, as superior lord, claimed the whole, besieged the viscount in the castle of Chalus, near Limoges, in order to make him comply with his demands. The garrison offered to surrender, but Richard was determined on revenge; and as he was surveying the castle with Marcadée, leader of his Brabançons, he was struck by an arrow, aimed at him by Bertrand de Gourdon. The wound was not considered as mortal: the place was assaulted and taken, and the whole garrison executed, except Gourdon, who had wounded him, and who was reserved for a more savage execution. By the unskilfulness of the surgeon, the wound, which was at first but slight, exhibited the most dangerous symptoms, and the king felt that his end was approaching. He sent for Gourdon, and asked him what had induced him to make an attempt upon his life; to which the man boldly replied, "You killed, with your own hands, my father and my two brothers, and you intended to have hanged myself: I am now in your power, and you may take your revenge, by inflicting upon me the severest torments; but I shall endure them with patience, provided I can think that I have been so happy as to rid the world of such a nuisance." Richard, struck with the magnanimity and reasonableness of the reply, and probably humbled and penitent by the near approach of death, ordered Gourdon to be set at liberty, and a sum of money to be given him; but Marcadée, unknown to the dying king, seized the unhappy man, caused him to be slayed alive, and then hanged. Richard died in the tenth year of his reign, and the forty-second of his age, leaving no issue behind him. The most shining parts of his character are his military talents. He loved glory, and chiefly military glory; and as his conduct in the field was not inferior to his valour, he seems to have possessed every talent necessary for acquiring it. His resentments were high, and his pride unconquerable. He was distinguished by all the good as well as bad qualities incident to an impetuous and vehement spirit: he was open, frank, generous, sincere, and brave; but revengeful, ambitious, haughty, and cruel. His talents were considerable

in the cabinet, as well as in the field. He was a passionate lover of poetry: some of his compositions in that line are said to remain; and he bears a rank among the Provençal poets and Troubadours, who were the first of modern Europeans that distinguished themselves by attempts of that nature.

Though the English pleased themselves with the glory which the king's martial genius procured them, his reign was oppressive and arbitrary, by the high taxes which he levied on them, and frequently without consent of the states, or great council. In the ninth year of his reign he levied five shillings on each hyde of land; and because the clergy refused to contribute their share, he put them out of the protection of the law, and ordered the civil courts to give them no sentence for any debts which they might claim. Twice in his reign he ordered all his charters to be sealed anew, and the parties to pay fees for the renewal. He established by law one weight and measure throughout the kingdom, which the mercenary disposition and necessities of his successor engaged him to dispense with for money.

RICHARD II., king of England, son of Edward the black prince, and grandson of Edward III., was born in 1366, and, on the death of his grandfather in 1377, he succeeded to the throne in his eleventh year. The chief authority of the state, at this time, was in the hands of his three uncles, *viz.* John, duke of Lancaster; Edmund, earl of Cambridge, afterwards duke of York; and Thomas of Woodstock, afterwards duke of Gloucester. A council of nine persons was now nominated to conduct the administration of government. The early part of the king's minority passed in wars with France and Scotland; the consequence of which was a formidable insurrection at home, produced by the taxes necessary for the public service. In 1381, the indecent conduct of a collector of the poll-tax at Deptford having provoked one Walter, by trade a tiler, to break his skull with a hammer, a flame was instantly kindled, which spread over Kent, and the neighbouring counties; so that, in a short time, a body of 100,000 men was collected on Blackheath. Their object was not merely to put an end to an arbitrary tax, but to free the country from the personal servitude to which the lower classes were, at that time, in a great measure subjected. On their approach to London, they sent a message to the king, requesting a conference. He met them on the bank of the Thames, but was unable to satisfy their demands. In the rage of disappointment, they burst into London, committed great devastation, and excited universal consternation. At length ample charters of freedom were granted to them, and a general pardon for all past offences. The insurgents now dispersed, but the principal leader, Wat Tyler, at the head of the Kentish men, remained in London, and was unsatisfied with the concessions granted by the monarch. He met the king in Smithfield, whom he addressed with much insolence, and making the most extravagant demands, Walworth, lord mayor of London, drew his sword and felled him to the ground. While the rioters stood astonished with the fall of their leader, the king, with great presence of mind, rode up alone, and exclaiming that he would be their leader, drew them off involuntarily into the neighbouring fields. The monarch would willingly have pardoned the insurgents, and confirmed to them the charters which had been extorted by force; but other insurrections being excited, his advisers caused him to revoke all the charters that had been extorted from him, and to issue commissions for the trial of the rioters, many of whom were executed.

Richard, when he was sixteen years old, espoused Anne, daughter of the late emperor Charles IV.; after this he began

to exercise a very tyrannical spirit, notwithstanding the early promise of his reign, and he took the great seal from Scrop, who had refused to set it to certain extravagant grants of lands made to courtiers. A war with France and Scotland, and the ambitious projects of the duke of Lancaster, disquieted some succeeding years. In 1385 Richard marched with a large army into Scotland, and ravaged the country to Edinburgh and Perth, both which towns he burnt; in the mean time a Scotch army was making a destructive inroad into England. The duke of Lancaster being absent, prosecuting his claim to the crown of Castile, the king's younger uncle, the duke of Gloucester, a man of popular manners and dangerous ambition, became a leader of the opposition to the administration of the king's favourites. By his influence an impeachment was sent up to the lords against the chancellor; and though the king withdrew, with his court, to Eltham, he was intimidated into a dismissal of his minister, who was afterwards stripped of his estates, and committed to custody. The parliament now felt themselves strong enough to proceed to active measures, and they went so far as to divest the king of all his authority, by obliging him to sign a commission, appointing a council of regency, consisting of fourteen persons, to whom the sovereign power was transferred for a year. The king now, in the twenty-first year of his age, was reduced to a state of complete insignificance, but he held frequent consultations with his friends relative to the means of emancipating himself; and in the year 1387, making a progress to the north, he summoned a council of his friends at Nottingham, by which questions were proposed to the judges concerning the legality of the commission which he had been compelled to sign. They unanimously declared it to be a violation of the royal prerogative, and pronounced all who had joined in the execution of it, as guilty of a capital offence. The duke of Gloucester and his party began now to make preparations to maintain their cause by force of arms. Being by much the stronger party, they obliged the king to accept of terms, and at the ensuing meeting of parliament the five principals in the king's council were impeached, and condemned to death. The judges, who had given their opinion in favour of the king, were all found guilty of high-treason, but the punishment of death was commuted for imprisonment in Ireland during life. In 1389 Richard entered the council, and, in a resolute tone, observed, that he was of full age to take the government into his own hands: his enemies submitted, and he granted a general amnesty.

Several years of tranquillity ensued, and the return of the duke of Lancaster formed a counterbalance to the influence of the duke of Gloucester. In 1394 Richard visited Ireland at the head of an army, in order to settle the affairs of that island, which he accomplished, and then returned. Although no acts of notorious misgovernment had been committed by the king for a considerable period, yet his private character and mode of life tended to disgrace him in the eyes of his subjects. He was indolent and averse from business, and spent all his time in conviviality and amusement, admitting jesters and persons of the meanest rank and station to his intimacy, and laying aside all the proper dignity of rank. He was still governed by favourites, who were the real distributors of every grace from the crown, so that the king was little better than a cypher. By Gloucester and his party the most criminal designs were imputed to Richard, which led the king, by the advice and solicitation of his adherents, to apprehend the duke and his two accomplices, the earls of Arundel and Warwick. This plan was executed in 1397; the duke was sent over to Calais in close custody, while the earls were committed to prison. A parliament

was then assembled, before which the culprits were impeached of high treason. Lord Arundel was condemned, and executed; the earl of Warwick was also convicted, and condemned to perpetual banishment. The duke of Gloucester was said to have died of an apoplexy, but it was soon discovered that he had been suffocated. Although the proceedings of parliament were favourable to the royal authority, yet much ill-will prevailed in the nation on account of its severities, and troubles were continually breaking out among the nobles. A quarrel between the dukes of Hereford and Norfolk, arising from a charge brought by the former against the latter, of slanderous words spoken concerning the king, was the cause of the revolution that terminated the reign. Richard interposed his authority and banished them both; but it was agreed, that both exiles might receive, by their attorneys, any inheritance that should fall to them during their absence. In 1399, John of Gaunt, duke of Lancaster, died, and his son, the duke of Hereford, became heir to his vast estates, which Richard, in defiance of the agreement, seized as property lapsed to the crown, and the attorney who claimed them for the duke was even condemned as a traitor. While the nation was full of discontent on account of this act of tyranny, Richard went to Ireland, and, during his absence, Henry of Bolingbroke, as the duke of Hereford, invited by his numerous partisans to make use of this opportunity, came over from France, and landed in Yorkshire, and being joined by the earls of Northumberland and Westmoreland, and other men of rank, proceeded towards the south, at the head of 60,000 men, pretending that their sole intention was to recover the duchy of Lancaster. The duke of York, who had been left regent of the kingdom, joined Henry; and Richard, having heard these facts, intended to withdraw into France. He was, however, taken and thrown into Flint castle, from whence he was taken to London. His deposition being resolved on, thirty-five articles of accusation were drawn up against him, which, however informal, and many of them unjust, were considered as quite sufficient to justify the measures taken against him, and Richard was deposed Sept. 30, 1399. Henry at the same instant stood forth, and claimed the crown, which was without hesitation awarded to him. He declared that the life of the dethroned king should be safe, and he was committed for safe custody to the castle of Pomfret; but the usual fate of deposed monarchs soon awaited him. Indeed it was easy to foresee that he would not long remain alive in the hands of such barbarous and sanguinary enemies. Historians differ with regard to the manner in which he was murdered. It was long the prevailing opinion, that sir Piers Exton, and others of his guards, fell upon him in the castle of Pomfret, where he was confined, and dispatched him with their halberds. But it is more probable, that he was starved to death in prison; and after all sustenance was denied him, he prolonged his unhappy life, it is said, for a fortnight, before he reached the end of his miseries. This account is more consistent with the story, that his body was exposed in public, and that no marks of violence were observed upon it. He died in the thirty-fourth year of his age, and the twenty-third of his reign. He left no posterity, either legitimate or illegitimate.

All the writers who have transmitted to us the history of Richard, lived during the reigns of the Lancastrian princes; and candour requires, that we should not give entire credit to the reproaches which they have thrown upon his memory. But, after making all proper allowances, he still appears to have been a weak prince, and unfit for government, less for want of natural parts and capacity, than of solid judgment

and good education. He was violent in his temper; profuse in his expence; fond of idle show and magnificence; devoted to favourites, and addicted to pleasure; passions, all of them, the most inconsistent with a prudent economy, and consequently dangerous in a limited and mixed government.

This prince lived in a more magnificent manner than perhaps any of his predecessors or successors. His household consisted of 10,000 persons. He had 300 in his kitchen, and all the other offices were furnished in proportion. It must be remarked, that this enormous train had tables supplied them at the king's expence, according to the mode of that age. Such prodigality was probably the source of many exactions by purveyors, and was one chief reason of the public discontents.

RICHARD III., king of England, born in 1450, was the youngest son of Richard, duke of York. On the accession of his brother, Edward IV., he was created duke of Gloucester, and during the vicissitudes in the early part of Edward's reign, he adhered most closely to him, and served him with courage and fidelity. He is said to have had a hand in the slaughter of Edward, prince of Wales, after the battle of Tewkesbury, and to have been the author, if not the real perpetrator, of the murder of Henry VI. in the Tower, but the ferocity of his disposition was in him united with deep policy and dissimulation. He married, about the year 1473, Anne, the widow of the prince of Wales, already mentioned, who was daughter of Neville, the great earl of Warwick. His elder brother, Clarence, had married the other daughter, and a violent dissension took place between them, on account of the division of the property. Richard, who found Clarence an obstacle to his views of aggrandizement, combined with the adversaries of that unfortunate prince in accusations which proved his destruction. On the death of Edward (see his article) in 1483, the duke of Gloucester was appointed the protector of the kingdom. He immediately caused his nephew, the young Edward V., to be proclaimed king, and took an oath of fealty to him. There were at this time two great factions in the nation, of which the leaders were the duke of Buckingham and lord Hastings. Both these courted the duke of Gloucester, who pretended a steady friendship for each when apart, while he was pursuing schemes of the blackest ambition. His first object was to get rid of those who were connected with the young king by blood; and after spending an evening in company with Rivers, Grey, and sir Thomas Vaughan, he caused them to be arrested the next morning, and committed to Pomfret castle, at the same time dismissing all the king's attendants and servants. He shortly after caused the prisoners at Pomfret to be put to death without the form of trial; and on the very day of their execution, at a council held in the Tower, a cry of treason was raised by his order, on which a party of armed men entered, who seized the archbishop of York, the bishop of Ely, lord Stanley, and lord Hastings, of whom the three first were committed to custody, while Hastings was led to immediate death. After this, his next step was to establish, with or without evidence, the illegitimacy of Edward's children, to make way for himself on the throne. This he did by attacking the chastity of his own mother, who, he said, had been true to her husband only in the case of himself, and that to Edward and Clarence there were different fathers. These pleas were zealously advocated by his adherents, and among others by Dr. Shaw, brother to the lord mayor of London, who dwelt upon them with much eloquence, in a sermon which he preached at St. Paul's Cross. The duke of Buckingham afterwards, in a  
speech

speech before the corporation and citizens of London, enlarged upon the title and virtues of the protector, and then put the question to his audience, whether they chose the duke of Gloucester for king? On their silence, he repeated the question with more importunity, and at length a few voices cried out "God save king Richard." This was continued into a public declaration in his favour, and Buckingham, with the lord mayor, repaired to the protector with a tender of the crown. He first affected alarm and suspicion, and then pretended loyalty to his nephew, and unwillingness to take such a burden upon himself. At length he accepted the offer, and Richard was proclaimed king on the 27th of June 1453. The deposed king and his brother were never more heard of, they were probably murdered in the Tower.

Richard was now extremely liberal towards those who had been instrumental in the change, and took other methods to court popularity. He made a progress with a splendid retinue through several of the towns, and at York was a second time crowned, on which occasion he created his only son prince of Wales. He soon began to display all the qualities of a most cruel tyrant, which so disgusted the whole nation, that designs were formed to hurl him from the throne. A conspiracy was excited against him, in favour of Henry, earl of Richmond, which he discovered and quelled. This failure appeared to seat the king more firmly on the throne, and he took advantage of his situation by calling a parliament, in which many good laws were passed, the progeny of Edward IV. were bastardized, and the crown settled on himself and posterity. The death of his son, soon after, was a severe stroke to him in the midst of his prosperity, which was followed by that of his wife; the last was imputed, but without any evidence, to the effects of poison. To prevent a projected marriage between Elizabeth, the eldest daughter of his brother Edward, and the earl of Richmond, Richard determined to marry her himself; as this union would have been very detrimental to the earl's interest, he hastened his preparations for another expedition to England, and in August, 1485, landed an army at Milford-haven. Richard, informed of the advance of his rival, took the field, and met him, with an army of nearly 15,000 men, at Bosworth, in Leicestershire. The battle was fought on the 23d of August; in which the king, finding his situation desperate, rushed against his competitor, slew his standard-bearer, and was upon the point of encountering the earl himself, when he was himself slain. The body of Richard was found in the field, stripped naked, and carried across a horse to Leicester, where he was interred in the Grey friars' church-yard. Thus fell this hated tyrant, after having possessed the throne about two years and two months. The historians, says Hume, who favour Richard, maintain, that he was well qualified for government, had he legally obtained it; and that he committed no crimes but such as were necessary to procure him possession of the crown: but this is a poor apology, when it is confessed, that he was ready to commit the most horrid crimes that appeared to him necessary for that purpose; and it is certain, that all his courage and capacity, qualities in which he really seems not to have been deficient, would never have made compensation to the people for the danger of the precedent, and for the contagious example of vice and murder, exalted upon the throne. In person, Richard has been represented as of small stature, deformed, and of a forbidding aspect, but it is probable that the detestation of his character has aggravated his bodily defects. His memory lives in popular tradition, as that of the most odious tyrant that ever filled the English throne. For the foregoing

articles we are chiefly indebted to the histories of Hume and Henry.

RICHARD, JOHN, a French advocate and theological writer in the 17th and the early part of the 18th centuries, was born at Verdun, in Lorraine, about the year 1638. The first part of his education he received at Pont-a-Mousson, and was then sent to Paris, where he studied law and divinity. Afterwards he was admitted an advocate at Orleans; but more for the sake of possessing the rank and privileges connected with that title, than from any design to practise at the bar. His inclination led him to devote his time and talents to the composition and publishing of sermons. By his numerous productions of this description he acquired celebrity. In the year 1700 he began to publish a compilation, under the title of "A Moral Dictionary, or, Universal Pulpit-Science," which, in 1715, was extended to 6 vols. 8vo. It consists of striking sentiments and reasonings on a great variety of subjects, selected from the works of French, Spanish, Italian, German, and other divines, arranged in alphabetical order.

RICHARDIA, in *Botany*, was named by Houtstoun, in honour of Richard Richardson, M.D. F.R.S. who resided on his own estate at North Bierly, Yorkshire, and died at an advanced age, about the year 1740. His fortune rendering him independent of medical practice, as a maintenance, he bestowed great attention on the botany of his own country, and his name occurs continually in the publications of the early part of the 18th century, as the correspondent of Ray, Sloane, Dillenius, &c. He communicated several papers, on various subjects, to the Royal Society; none of them botanical; see Pulteney's Sketches, v. 2. 185.—Linn. Gen. 174. Schreb. 230. Willd. Sp. Pl. v. 2. 222. Mart. Mill. Dict. v. 4. Juss. 198. Lamarck Illustr. t. 254. Gærtn. t. 25. (Ricardia; Rel. Hoult. 5. t. 9.)—Class and order, *Hesandria Monogynia*. Nat. Ord. *Stellata*, Linn. *Rubiacea*, Juss.

Gen. Ch. *Cal.* Perianth superior, of one leaf, in six deep, erect, pointed segments, half the length of the corolla. *Cor.* of one petal, funnel-shaped; limb in six acute, erect segments. *Stam.* Filaments six, very short, inserted into the tube of the corolla, alternate with its segments; anthers small, roundish, between the segments. *Pist.* Germen inferior, three-lobed; style thread-shaped, the length of the stamens, three-cleft in the upper part; stigmas obtuse. *Peric.* none. *Seeds* three, obovate, gibbous, rounded at the outer side, angular at the inner, crowned with the calyx.

Obf. Gærtner has observed that the calyx and corolla have sometimes eight segments, with eight stamens.

Ess. Ch. Calyx in six segments. Corolla of one petal, funnel-shaped. Seeds three, crowned with the calyx.

1. *R. scabra*. Linn. Sp. Pl. 470. Willd. n. 1.—Gathered by Houtstoun at Vera Cruz.—A rough hairy plant, with the habit of a *Spermatocoe*. The stem is tall, purplish, with opposite branches, its hairs curved downwards. *Leaves* opposite, crowded, ovate, pointed, entire, hairy, with many straight, parallel ribs. *Flowers* encompassed with numerous hairy bristles. *Calyx* bristly.

RICHARDSON, JONATHAN, in *Biography*, a painter, and a writer on the art of painting, was born about the year 1665. He was intended by his father for the law, but at twenty years of age was permitted to desert that profession, and follow the bent of his inclination for painting. He then became the disciple of Riley, with whom he lived four years, and finally connected himself by marrying his niece. The degree of skill which he attained, by no means

corresponded with the ideas he entertained of the art, which were certainly of a just and elevated kind. There are, however, great strength, roundness, and boldness in the colouring of his heads, which are drawn and marked in the manner of Kneller, with freedom and firmness; though the attitudes in which they and his figures are placed, the draperies which clothe the latter, and the back-grounds from which they are relieved, are insipid and tasteless. It is certainly a very curious circumstance, that, when he wrote with so much fire and judgment, as is displayed in his *Essay on Criticism*, and the *Science of a Connoisseur*, dived so deep into the inexhaustible stores of Raphael, and was so smitten with the native lustre of Vandyke, he should so ill apply to his own practice, the fugacious rules and hints he gave to others. Full of theory, profound in reflections on the art, and possessed of a numerous and excellent collection of drawings, he appears to have possessed no portion of invention, as applicable to the painter's art, and drew nothing well below the head; plainly manifesting the peculiarity of taste or feeling which leads to excellence in that profession.

Thus much, however, must be said of him, that when Kneller and Dahl were dead, he stood at the head of the portrait painters in this country, and practised in it sufficiently long to acquire a tolerable competency. He quitted his occupation some years before his death, when Hudson, who had married one of his daughters, maintained the family honours for a while. Richardson himself, by temperance and tranquillity of mind, enjoyed a life, protracted amidst the blessings of domestic friendship, to the advanced age of eighty, and then died respected and lamented. He had had, a short time previously, a paralytic stroke that affected his arm, yet never disabled him from taking his customary walks and exercise; and it was after having been in St. James's park, he departed suddenly, at his house in Queen-square, on his return home.

The sale of his collection of drawings, in February 1747, lasted eighteen days, and produced 2060*l.*; his pictures about 700*l.* He left a son, who painted and drew also, and who appears to have been a perfect pattern of filial reverence and affection.

RICHARDSON, SAMUEL, in *Biography*, was born in 1689, in some part of Derbyshire, to which county his father had retired from business, which he had carried on in London. In very early life he was characterized for his love of reading, and while a mere boy, he displayed the uncommon qualities of a taste for letter-writing and female society. At the age of thirteen, he was so much in the confidence of three young women, as to be employed by them in making draughts of letters to their lovers; and, at this early period, such were his fidelity and discretion, that not one of them suspected him to be the writer for the others. He was apprenticed to a printer, whom he served most conscientiously for the full term of seven years, stealing from the hours allowed to rest and recreation, his opportunities for mental improvement. After the expiration of his apprenticeship, he passed several years as journeyman in a printing-office, and then set up in business for himself. His habits of diligence and accuracy, and his honourable dealings, soon gained him employers and friends; and he was often applied to by book-sellers for making indexes, and writing prefaces and dedications. The immediate occasion of his becoming a novel-writer, was an application made to him by two book-sellers, to write for them a volume of letters in a common style, on subjects that might serve as models for the use of those who had not the talent of inditing for themselves. He extended the idea to the conveying of instruction in thinking and

acting upon important occasions; and in composing some letters for the salutary purpose of teaching young women going out to service how to avoid the snares that might be laid for their chastity, a story which he had heard many years before of a real occurrence came into his mind, and became the parent of "Pamela." This work was published in 1740, and was received with extraordinary applause by readers of all ranks. It brought the author into immediate notice; but his "Clarissa," of which the first two volumes appeared in 1748, placed him in the first rank of novelists. "A tale so varied by character, so minutely developing the movements of the human heart, so pathetic in its circumstances, and presenting so sublime and perfect an image of female purity, had never before been given to the public. The interest it excited during its progressive appearance, especially among female readers, was incredible, and the fate of no real personage could have agitated more bosoms than that of the fictitious heroine." Rousseau, in speaking of it, asserts, that "nothing was ever written equal or approaching to it in any language." The "History of Sir Charles Grandison," his concluding work, appeared in 1753, which was intended to give the world an example of a perfect man, uniting the fine gentleman and the Christian.

While he was advancing in the career of his literary fame, he was not inattentive to that improvement of his fortune which his assiduity and integrity in his profession so well merited. His first great public employment was that of printing the "Journals of the House of Commons," in 26 vols. folio, which he obtained through the recommendation of his friend, Mr. Speaker Onflow. In 1754 he rose to be master of the Stationers' company, and in 1760 he purchased a half of the patent of law-printer to his majesty. He was twice married, and had several children, but four daughters only grew up to solace his declining years. He was the substantial valuable friend in difficulty, distress, and sickness. He was most exemplary in temperance both of body and mind, and in the faithful discharge of every moral duty. He died at the age of seventy-two, and was interred by the side of his first wife in St. Bride's church. The writings of Richardson, exclusive of the three novels above referred to, were of no great consequence. They are chiefly the "Familiar Letters" already noticed; an edition of "Æsop's Fables," with reflections. His "Correspondence," selected from the original manuscripts, was published in six volumes, in the year 1804, with a biographical account of the author, by Mrs. Barbauld, to which the reader is referred for more particulars relating to Mr. Richardson.

RICHARDSON'S Bay, in *Geography*, a bay on the S.E. coast of Jamaica.

RICHAW, a town of Prussia, in the province of Oberland; seven miles S. of Liebitz.

RICHBOROUGH, a hamlet, and a district of land, in the parish of Ash, lower half hundred of Wingham, lathe of St. Augustine, and county of Kent, England, is situated about two miles N.W. from the town of Sandwich. It is noted in history as the site of the Roman post which guarded the southern entrance of the Portus Rutupensis, whence it derived its original name of Rutupium. The fortress which defended the northern entrance was called Regulbium; and is noticed under the article RECTIVER. This port, in Roman times, appears to have been the most famous of any in Britain; for it is noticed in the writings of Lucan, Juvenal, and Ausonius; and also in those of Tacitus, Ammianus Marcellinus, and Orosius. It likewise occurs in the Geography of Ptolemy, in the Itinerary

of Antoninus, in the Index of the writer of Ravenna, in the Peutingerian Tables, and in the Notitia of the western empire. In those days the site of Rutupium was a small island, though at present it is a considerable distance within land. This is proved by the testimony of many ancient writers; by the appearance of the surrounding country; and the fact of strata of sea-sand being discovered by digging into its surface. The period when it was deserted by the ocean was probably between the fourth and sixth centuries, as about that time the name of Sandwich, which rose on the ruins of the Rutupian haven, begins to be mentioned in ancient writings as a frequented port.

Richborough was anciently called *Rhutupia*, *Portus Rutulensis*, or rather *Portus Rhotupensis*, *Rhotupsis Portus*, *Rhotupie Statio*, and *Rhotubi civitas et portus*, among the Greek and Roman writers, by the Saxons denominated *Reptacester*, and by others *Ruptimouth* and *Richberg*. After the Saxons had commenced their piracies on the coast, the legio secunda Augusta, which had been brought from Germany by Claudius, and had been for many years stationed at Hea Silurum, in Wales, was removed hither and commanded by an officer under the count of the Saxon shore. Under the Saxons it was still considerable, and the place in which king Ethelbert resided.

Much diversity of opinion prevails among the learned as to the precise situation of the Urbs Rutupia, some identifying it with the castle, and others placing it along the adjacent shore, while a third class of writers fix it at Canterbury. Among those who espouse the last opinion is the late bishop Douglas, who has discussed the subject with great learning and ingenuity, in a paper printed in the first volume of the "Bibliotheca Topographica Britannica." With his view of the matter, indeed, we are strongly inclined to coincide; for it seems impossible that the city could stand within the narrow limits of the castle, and there are no vestiges in its vicinity of foundations of extensive buildings, a circumstance which could scarcely have happened, if such buildings had ever existed. Of the fortress itself, however, much yet remains to solicit the examination and excite the amazement of the antiquary. In form it appears to have been, when complete, a regular parallelogram; but the greater part of the eastern wall is now destroyed. The whole site exterior to the ramparts occupied six acres, one rood, and eight perches of ground; and the area within the walls five acres, three roods, and eight perches. The walls were flanked by round projecting towers at the angles, and by square ones at irregular distances along the sides. There are marks of two of these in the west wall, and of two others, besides the Porta-Decumana, in the north wall, and of two more in the south wall; in which undoubtedly was a third, that has fallen down the bank. These square towers, projecting about eight feet from the wall, were solid nearly eight feet from the foundation, above which they were hollow. In the main wall within these towers are four large, round, smooth holes in a row, each about nine inches in diameter, and penetrating about eight feet into the substance of the main wall. Below these are smaller holes, four inches in diameter, that run about ten inches into the wall; all which seem to have served for the insertion of beams, to support an apparatus of defensive machinery. Within the area, towards the north-east corner, and beneath the surface of the ground, is a solid rectangular platform of masonry 144 feet long, 104 feet wide, and 5 feet thick. It is composed of bolders and coarse mortar; and is covered on the upper side with a coat of the same sort of mortar to the depth of six feet. In the centre of the platform is the base or foundation of a building

in the shape of a cross, which rises about five feet above the level of the platform. The shaft of this cross measures 87 feet in length and  $7\frac{1}{2}$  feet in breadth; and its transverse is 46 long and 22 wide. In the western wall of the castle was a large opening, 34 feet wide, where, about five feet under the surface, is part of another platform, consisting of large square blocks of stone, and measuring 24 feet 11 inches in breadth. There is no appearance of any superstructure having been raised from this foundation. Near the middle of the north wall is the oblique entrance, or "Porta-Decumana," which is narrow; and, from the holes remaining in the walls, seems to have been furnished with good timber defences. The exterior passage, running parallel with the main wall, is about four feet and a half wide, having a channel at the bottom for carrying off water from the higher ground within the castle. Many Roman coins and other antiquities have been discovered as well within the area of the fortress, as in its vicinity; and at the distance of about 460 yards from its south-western angle, the remains of a Roman amphitheatre are yet distinctly visible, though its banks are much mutilated and levelled by the operations of husbandry. Leland informs us, in his Itinerary, that there was formerly "a little parochial church of St. Augustine and an hermitage" within the castle. The church was a chapel of ease to that of Ash; and is mentioned as standing in the reign of Edward VI. Antiquities of Richborough and Reculver, abridged from the Latin of archdeacon Battely, Lond. 8vo. 1774. Bibliotheca Topographica Britannica, vol. i. 4to. Lond. 1780. Beauties of England, &c. vol. viii. by E. W. Brayley. King's Munimenta Antiqua, vol. iii.

RICHEA, in *Botany*, so named by Mr. R. Brown, in memory of M. Riche, one of the naturalists who accompanied the expedition in search of La Perouse, and being in a confirmed consumption at setting out, died in the course of the voyage. Labillardiere has dedicated a genus to this companion of his labours, but it proves no other than what Forster had previously published as CRASPEDIA; see that article. Brown Prodr. Nov. Holl. v. 1. 555.—Class and order, *Pentandria Monogynia*. Nat. Ord. *Eparcrideae*, Brown.

Ess. Ch. Calyx membranous, simple, in five deep segments. Corolla of one petal, closed, hood-like, splitting transversely; its abrupt base remaining. Stamens inserted into the receptacle, permanent. Five scales under the germen. Capsule superior, of five cells. Receptacles separate, pendulous from the top of the central column.

1. *R. dracophylla*.—Gathered by Mr. Brown, in Van Diemen's island. A shrub, varying remarkably in stature, being only eighteen inches high on the summits of the mountains, but in woods at their sides becoming a small tree, of the height of ten feet. "It has altogether the habit of Labillardiere's *Dracophyllum montanum*, differing only in the singular economy of the corolla, which however seems sufficient to mark it for a distinct genus." Brown. Notwithstanding the opinion of this judicious author, we presume to think his *Cyrtanthe*, Prodr. Nov. Holl. v. 1. 555, scarcely sufficiently distinguished from the above. Their corollas and capsules agree; the only difference consisting in the foliaceous calyx of *Cyrtanthe*, and its want of scales below the germen. We feel the more disposed to unite these genera, as there is but one known species of either.

RICHEFORT, or RICCIAFORT, JOHN, in *Biography*, a Netherlandish musical composer of considerable eminence. He is placed by Walther in the middle of the sixteenth century; but he was certainly a composer many years before

more that period, as we find his name not only in the second book of "Motetti della Corona," published at Foffembro, 1519, and preserved in the British Museum, in which collection he was author of the fourth motet, "Miseremini mei;" but to a motet in a music-book, preserved at Cambridge, of Henry VIII. when prince of Wales. Glareanus says, that "great praise is due in our times to the vocal compositions of John Richefort." In the museum collection of French songs, in four, five, and six parts, printed in the Netherlands during the sixteenth century, there is one by this author for three tenors and a base, which, though it would be thought monotonous by modern ears, has great merit for the artful contexture of the parts, which are moving throughout in close fugue and imitation. The words, indeed, of these old songs are generally as rude and devoid of meaning as those of our own country, equally ancient; this, however, contains a general censure of indiscriminate urbanity.

RICHELET, CÆSAR-PETER, a French writer, was born, in 1631, at Cheminon, in Champagne. He went, when young, to Dijon, where he superintended the education of the son of the marquis de Courtivron. About 1660 he went to Paris, was admitted an advocate, and began to plead at the bar. He became connected with d'Ablancourt and Patru, and acquired reputation from the attention he paid to the French language. In 1665 he was admitted to an academy of men of letters, which the abbé d'Aubignac had established at his own house. It appears that he was for some time placed about the dauphin, as one who might contribute to inspire that prince with the love of literature. He afterwards took up his abode in different parts of France, the enemies he made by his satirical disposition obliging him frequently to shift his residence. He died at Paris in 1698, at the age of 67. The principal work of Richelet is his "Dictionnaire François," of which the first edition was published at Geneva in 1680, 4to., and several have since been printed with additions. The last is that of the abbé Goujet, Lyons, 1759, 3 vols. fol. Richelet's Dictionary has been popular, though his orthography was much censured. He also published "Dictionnaire des Rimes;" "Les plus Belles-Lettres des meilleurs Auteurs François;" of this collection the best edition is that of Bruzen de la Martiniere, 1737, 2 vols. 12mo.; "A Translation of Garcilasso de la Vega's History of Florida;" and other works.

RICHELIEU, ARMAND DU PLESSIS, a famous prime minister of France, born at Paris in 1585, was the son of Francis du Plessis Richelieu, grand provost of France, and captain of the guards to Henry IV. He was brought up to the church, and after studying at the Sorbonne, went to Rome. At the early age of 22, he was consecrated bishop of Luçon. Though he had obtained some distinction by his proficiency in scholastic theology, his great object was to make his way at court. He concealed, under polite and insinuating manners, a determined disposition, and a spirit of intrigue well suited to a female regency and a reign of favourites. The queen-mother, Mary of Medicis, in 1616 nominated him her grand almoner and secretary of state. On the fall of the marshal d'Ancre, his protector, Richelieu retired from court, and affected to employ himself in writing books of devotion, while he was upon the watch to recover his credit. This point he at length gained, by effecting an accommodation between the queen and her son Lewis XIII., and the new favourite de Luynes rewarded his services by procuring him a cardinal's hat in 1622. After the death of Luynes, the court and kingdom fell into disorder through the intrigues of the great, and the con-

tentions of different parties, while all agreed in their defiance of the laws, and encroachments upon the supreme authority. A minister of equal talents and resolution was wanted to remedy these evils, and he existed in Richelieu. He had gained the confidence of the queen-mother, who recovered influence enough to introduce him into the council, notwithstanding the opposition of the other ministers, who feared him, and the repugnance of the king, who suspected his ambition, and was shocked with his licentious manners. In 1624 he found means to subvert all his rivals, and to possess himself of the whole authority of the crown.

The government, in his hands, soon assumed a tone of vigour and decision. He concluded the treaty of marriage between the prince of Wales and Henrietta, the French king's sister, in spite of the efforts of Rome and Spain, and equally disconcerted those courts by sending an army, and preventing the projected union with the Milanese. He next turned his arms against the French Calvinists, who, rendered disaffected by the frequent breaches of the treaties made with them, were become a kind of independent republic within the kingdom. Having first secured the friendship of Holland by pecuniary aid, he obtained the assistance of its fleet, and that of the English, against their brother Protestants of Rochelle, and expelled them from the isle of Rhé. It is acknowledged that the French monarchy dates from him its strength and independence. One of the principal enemies he had to contend with was Gaston, duke of Orleans, the king's brother. In consequence of a conspiracy entered into by this prince to assassinate the minister, and effect great changes at court, Richelieu arrested several of his confidants, and brought some of them to the scaffold. The danger he had incurred formed a pretext for giving him a body guard; and, by his pretended wishes to quit his station, he augmented his influence over his master. In 1627 war broke out with England, chiefly in consequence of the insolent vanity of the duke of Buckingham; and the Rochellers, with whom an accommodation had been made, were induced to favour the English. Richelieu thereupon resolved to reduce to submission a town which had long been the seat of an independent power, often leagued with the enemies of the kingdom; and after the duke of Buckingham had been obliged with disgrace to quit the isle of Rhé, Rochelle was invested on all sides. Richelieu in person took the command of the siege, and in order to prevent the arrival of succours by sea, he caused to be constructed a vast dyke in the ocean, by which all communication from abroad was cut off. This circumstance has given occasion to the cardinal's flatterers to compare him with Alexander before Tyre, and the work has been represented as one of the prodigies of his genius; but it was really that of the genius of the engineer Metezeau, and Richelieu only deserves the praise of adopting a bold design, and finding resources for putting it in execution. At length, after a noble resistance of eleven months, Rochelle submitted to famine; and the Protestants having lost their great bulwark, and all their other strong places, were rendered incapable of again acting as an armed party. It is to the credit of the policy and moderation of Richelieu that they were still allowed the free exercise of their religion.

In 1629 Richelieu received the patent of prime minister, and was nominated lieutenant-general of the army employed in the war in Italy, with powers so extensive, that the royal authority was reduced to a shadow. All that was great in the nation trembled before him. His foreign politics had chiefly in view the humiliation of the house of Austria; and by his treaty, in 1631, with Gustavus Adolphus, he enabled that great king to pursue those plans which brought

the empire to the brink of ruin. Gaston, duke of Orleans, in his retreat, with the duke of Lorraine, whose sister he had married for his second wife, plotted to excite a civil war for the expulsion of Richelieu, and his own return to consequence. His intrigues were discovered, and all his partizans were declared guilty of treason. The duke of Lorraine was compelled to abandon him, and incurred the loss of some of his strongest places. Gaston entered France with a small body of troops, accompanied by the brave duke of Montmorenci, but was defeated at Castelnaudari. Montmorenci was taken prisoner, and expiated his crime on the scaffold. The queen-mother herself was put under arrest, her servants were all sent to the Bastille, and she finally ended her days in exile at Cologne. The king supported his minister in all these severities, created him a duke and peer, and gave him the government of Brittany.

France had hitherto acted only as an ally to the Swedes in their hostilities against the house of Austria; but after their defeat at Nörtingen in 1634, the cardinal thought it necessary to enter as a principal into the war; and forming an alliance with Holland, and the dukes of Savoy and Parma, he caused war to be declared against the king of Spain in 1635. Events were at first unfavourable to the French arms, but at length became more prosperous to France, and the enemy was driven from her territories; the public finances were, however, exhausted, and recourse was had to the creation of a great number of venal offices, and other objectionable measures, to raise the necessary supplies. The talents of a financier do not seem to have been among Richelieu's qualifications, and he himself gave an example of profusion which increased the public discontent. No prime minister ever affected more state and splendour. The daily expence of his household was estimated at a thousand crowns, a prodigious sum at that period! His guards and attendants, his equipage and establishment, were rather upon the scale of a sovereign prince than of a subject, and he much surpassed his master in external pomp. Lewis betrayed a dissatisfaction on this account, which probably induced Richelieu to make him a present of his palace, since called the Palais Royal. He incurred great personal danger in 1642, from a conspiracy against his power and life, headed by Cingmars. (See his article.) The duke of Bouillon, and the duke of Orleans, entered into the plot, and negociations were opened with Spain for assistance. The good fortune of Richelieu produced a timely discovery of this treason, and Cingmars was beheaded. The duke of Bouillon was arrested, but made his peace by resigning his principality of Sedan. Gaston furnished proofs against his associates. The victim most worthy of compassion on this occasion was the son of the illustrious de Thou, who was capitally condemned only for not revealing a conspiracy which he disapproved. Richelieu was at this time lying dangerously sick at Tarascon. He proceeded to Lyons by water, and was thence carried to Paris in a kind of chamber, borne on the shoulders of his guards, breaches being made in the walls of the towns through which he passed to admit him. It soon appeared that he had not long to live, and he prepared for the final change with great firmness. In receiving the sacrament he declared, that in the course of his ministry, he had never any thing in view but the good of religion and the state—a declaration which the public opinion did not ratify. He died in December 1642, at the age of 58, worn out with toil and anxiety; but he terminated his career with fortitude and serenity, that astonished those who had beheld the sanguinary effects of his administration. Three mighty and successful projects immortalize the period of his government. He humbled the turbulent spirits of the great, he subdued the stubborn zeal of the Hugonots,

and he curbed the encroaching power of the house of Austria. Undaunted and implacable, prudent and active, no combinations of the powerful nobles could withstand his vengeance; no intrigues could elude his penetration; while he exalted the throne, he controlled a sovereign impatient to rule, and jealous of his authority; and while he extinguished the liberties of the people, he established among them discipline and order, and opened to them the paths to learning and renown. His own account of his public character is this: "I venture upon nothing till I have well considered it; but when once I have taken my resolution, I go directly to my end; I overthrow and mow down all that stands in my way, and then cover the whole with my red mantle." He was fonder of power than money, yet he amassed a princely fortune, which he bequeathed to the king. He was the author of some splendid establishments; he rebuilt the Sorbonne, founded the royal printing-house, the botanical garden, and the French academy. As a writer, he obtained some credit in the controversy with the opponents of the Catholic church; the most famous of his supposed works is, his "Treatise Politique," the authenticity of which has been the subject of warm controversy. The letters of Richelieu are said to be interesting, of which the best edition is that of 1696, in two vols. 12mo. Gen. Biog. Hist. of France, three vols. 8vo. 1790.

**RICHELIEU**, in *Geography*, a town of France, in the department of the Indre and Loire, and chief place of a canton, in the district of Chinon; 11 miles S. of Chinon; deriving its name from cardinal Richelieu, its founder. The place contains 3600, and the canton 12,525 inhabitants, on a territory of 320 kilometres, in 21 communes.

**RICHELIEU**, a river of Canada, issuing from lake Champlain, and first called "Chamblee," which name was changed by the French into Richelieu at fort Chamblee, and discharging itself into the river St. Lawrence, N. lat. 46° 1'. W. long. 72° 56'.

**RICHELIEU Islands**, a cluster of small islands in the river St. Lawrence, about 100 in number, 36 miles above Trois Rivières. N. lat. 46° 22'. W. long. 71° 7'.

**RICHEMONT**, a town of France, in the department of the Moselle, on the Orne; 10 miles S. of Thionville.

**RICHENBURG**, a town of Bohemia, in the circle of Chrudim; 10 miles S.E. of Chrudim.

**RICHENVEIR**, a town of France, in the department of the Upper Rhine; six miles N.N.W. of Colmar.

**RICHER, JOHN**, in *Biography*, a French astronomer and natural philosopher in the 17th century, of whom little is known, till he was admitted a member of the Royal Academy of Sciences at Paris in the year 1666, under the title of astronomer to that body. About 1671, Lewis XIV. sent him to the island of Cayenne in South America, for the purpose of making observations that might contribute to the improvement of astronomical science. After three years he returned, and gave the result of his labours in his "Astronomical and Physical Observations made at the Island of Cayenne," which are inserted in the seventh volume of the "Memoirs" of the Academy of Sciences. Cassini speaks of him with commendation in his "Elements of Astronomy." He died in the year 1696.

**RICHER, CLAUDE**, a learned priest and mathematician in the 18th century, was born at Auxerre in the year 1680. He was intended for the ecclesiastical profession when very young, and was sent to Paris for his education. Here he distinguished himself in 1701, when only arrived to the years of manhood, by a work which he published, entitled "Universal Gnomonics, or the Science of Dialling," &c. After this he was ordained priest, and remained about ten years

years almost an entire stranger to men of letters, engaged in the religious education of the young. About the year 1730 his passion for mathematical studies revived with great ardour, and he produced a work entitled "General Analysis, containing New Methods of resolving Problems of every kind, and of all degrees of infinity." This work was immediately adopted by the Academy of Sciences, and constitutes the eleventh volume of the "Memoirs." This volume was soon to be followed by three others; these, however, did not make their appearance, which was probably owing to a change in M. Richer's studies. By an accidental perusal of a fragment of Manetho, high priest of Heliopolis, in Egypt, he was induced to devote his whole attention to the most profound researches in ancient history. Notwithstanding the obscurity of this relic of antiquity, he conceived that he thoroughly understood it, and that it furnished him with a clue, by the aid of which he could unravel all the difficulties of ancient history, sacred and profane. Under the influence of this persuasion, he laboured night and day in attempting to illustrate it, till he had produced two immense folio volumes, which no one would undertake to print. As a specimen of his labours, he published "A Chronological Series of the Kings of Egypt, determined according to three simple Dynasties, from the Fragment of Manetho." He died about the year 1756.

**RICHERIA**, in *Botany*, a genus dedicated by Vahl, to the much neglected memory of Peter Richer de Belleval, first professor of Botany, as well as of Anatomy, at Montpellier, to whom Henry IV. of France committed the care of establishing a public garden in that university. This design was executed in the most skilful and splendid manner. Belleval published a catalogue of the garden in 1598, and a French treatise, in 1605, recommending an enquiry into the native plants of Languedoc. This last was accompanied by five plates, intended as a specimen of a future work, for which he subsequently prepared a number of engravings, rude and stiff in execution, but exhibiting many rare species. He never lived to publish these, and the plates remained neglected in the hands of his family, till Gouan recovered them, and sent impressions to Linnæus. At length Gillibert obtained the plates, and published them in 1796. The two pamphlets above-mentioned were re-published in 1785, by the celebrated and unfortunate Brouffonet; along with a treatise on the White Mulberry, by Olivier de Serres, originally printed in 1603. Richer de Belleval lived to see his garden destroyed by the fury of civil war, and was beginning to restore it, when he died in 1623, aged 65. His nephew accomplished the re-establishment of the garden, on a more extensive scale. M. Dorthes of Montpellier published, in 1786, *Recherches sur la Vie et les Ouvrages de Pierre Richer de Belleval*, in which every thing, that could be collected on the subject, is recorded. Some writers erroneously mention Belleval as the first botanist who gave copper-plate figures of plants. This honour is due to Fabius Columna, whose *Phytobasanos* appeared in 1592. We must not omit to mention, that Scopoli has named a genus *Billevalia*, a name, or something like it, which Belleval himself was fond of giving to the Lily of the Valley. Bruguière, in 1775, called a Madagascarean plant *Richeria*, but his genus has not been established.—Vahl *Eckg.* v. 1. 30. Willd. *Sp. Pl.* v. 4. 1122. Mart. *Mill. Dict.* v. 4.—Clafs and order, *Polygamia Dioecia*; *Dioecia Pentandria*; or rather *Pentandria Monogynia*. Nat. Ord. *Euphorbia*, Juss.

Gen. Ch. Male, *Cal.* Perianth of one leaf, permanent, in four or five ovate, acute, downy segments. *Cor.* Petals

four or five, roundish, the length of the calyx. Nectary four or five glands, at the base of the imperfect germen. *Stam.* Filaments four, five, or six, between the glands of the nectary, erect, longer than the calyx; anthers oblong, two-lobed, erect. *Pist.* Rudiment of a germen superior, conical, villous, style and stigma wanting.

Female, *Cal.* and *Petals* like the male. Nectary a rim round the base of the germen. *Stam.* none. *Pist.* Germen superior, ovate; style very short; stigmas three, revolute, channelled above. *Peric.* Capsule coated, ovate, smooth and even, of three cells, with six valves, separating at the base. *Seeds* solitary, pulpy-coated, pendulous from the top of the central column.

Ess. Ch. Male, Calyx four or five-cleft. Petals four or five. Nectary four or five glands, at the base of the imperfect germen. Stamens four or five.

Female, *Cal.* and *Cor.* like the male. Nectary a rim at the base of the germen. Style very short. Stigmas three, revolute. Capsule coated, of three cells and six valves, splitting at the base. Seeds solitary, pulpy.

1. *R. grandis*. Vahl. *Eclog.* v. 1. 30. t. 4.—Gathered by Ryan, on the sulphur mountain in the island of Montserrat. A tree of a great size. *Leaves* alternate, stalked, oblong, acute, entire, coriaceous, smooth, veiny, six or seven inches in length; very much contracted at the base. *Spikes* axillary, solitary, longer than the footstalks, lax. *Capsule* the size of a hazel-nut. The discoverer of this rare tree is said to have found some of the flowers perfect as to *stamens* as well as *pistil*. Hence, notwithstanding the slight differences in the nectary, we should incline to place the genus in *Pentandria Monogynia*.

**RICHFIELD**, in *Geography*, a town of America, in Otsego county, New York, taken from Otsego township, and incorporated in 1792.

**RICHFORD**, the north-easternmost township of Franklin county, Vermont, situated on Missisquoi river; containing 442 inhabitants.

**RICH-HILL**, a post-town of the county of Armagh, Ireland; 62 miles N.W. from Dublin, and four miles E. from Armagh.

**RICHLAND**, a district of South Carolina, bounded S. and S.W. by Congaree and Broad rivers, and E. by Wateree river, which divides it from Kershaw and Clermont counties.—Also, a township of Bucks' county, in Pennsylvania, containing 1317 inhabitants.

**RICHMAN'S ISLAND**, a small American island on the coast of Cumberland county, in the state of Maine; four leagues N. from Wood island and one league W. of Portland. Few vessels put in here, except coasters. Wood island is in N. lat. 43° 50'. W. long. 69° 37'.

**RICHMOND**, a borough and market-town in the wapentake of Gilling-West, north riding of Yorkshire, England, is situated on the banks of the river Swale, at the distance of 48 miles N.W. from York, and 293 miles N.N.W. from London. It was anciently much celebrated for its castle, which was founded by the first earl of Richmond, Alan, son of Hoel, count of Brittany. This nobleman, who was nearly related to William, duke of Normandy, accompanied that prince in his expedition to England; and in reward for his services, received from him all the forfeited estates of the brave Edwin, earl of Mercia. This grant was made during the time William was engaged in the siege of York, and is peculiarly remarkable on account of its brevity. Alan immediately after married Hawise, the conqueror's daughter; and being thus loaded both with riches and honour, built the castle, and part of the town of Richmond, to protect his family and his estates against the disinherited and outlawed

## RICHMOND.

outlawed Englishmen in those parts. Having no issue by his lady, the earldom of Brittany devolved to Conan le Grosse, his son by a second wife; and Alan, furnished the Black, son of Hawise by a former husband, obtained the earldom and estates of Richmond. During the reigns of our Norman kings this title and property were possessed by several different families, some of whom were allied to the blood royal, both of England and France. Edward III. conferred the estate on his third son, John of Gaunt, who afterwards surrendered it in exchange for some other lands. The same monarch gave Richmond, with his daughter, in marriage to John, earl of Montford and duke of Brittany, who was furnished the Valiant. During the wars of York and Lancaster, both the title and the estates several times changed possessors, and at length were vested in the crown by the accession of Henry, earl of Richmond, to the throne, under the title of Henry VII. By his successor, Henry VIII., Richmond was constituted a duchy in the person of his natural son, Henry, who died without issue in the year 1535.

The town of Richmond is comparatively limited in extent and population; containing, according to the late parliamentary returns, only 512 houses, and 3056 inhabitants. Its fine situation, however, and the character of its buildings, which are in general constructed of stone, give it a dignified and interesting appearance. It occupies the top and declivity of a lofty eminence boldly rising from the river Swale, which winds round the town and the castle in a semicircular direction. The chief trade of this place is that of knit woollen stockings, in which men, women, and children, are employed. The market day is Saturday, weekly; and there are besides four annual fairs. The market here is one of the largest in the north of England for corn; and the fairs are noted for a great supply of horses, horned cattle, and sheep. Richmond is a borough by royal charter, and sends two representatives to parliament, who are elected by "those persons who are owners of ancient burgages in the said borough, having a right of pasture in a common field, called Whitechiff pasture." The government of the town is vested, by the charter of queen Elizabeth, in a mayor, recorder, twelve aldermen, twenty-four common council-men, and other inferior officers. The petty sessions for the wapentake of Gilling West are holden here.

The castle of Richmond stands on the south side of the town, on a bold eminence, overlooking the Swale, which runs in a deep valley beneath. On all sides the approach to it is steep and difficult, except on the north, where the ascent is gradual. The castle is now in a very ruinous condition, but it still retains the features of former grandeur and importance. The keep-tower, of which the shell is nearly entire, is of great altitude; and its exterior walls are more than eleven feet thick. The lower story is supported by a vault column of stone in the centre, from which spring circular arches closing the top. The staircase only reaches to the first chamber, the rest of it being dilapidated, as the floors of the two upper rooms are fallen in. In this keep is a well of excellent water. The ruins of several other parts of this castle yet remain. In the south-eastern corner of the area is a ruinous tower, below which is a dungeon, about fourteen feet deep. The ground covered by this fortress measures nearly six acres in extent, and is the property of the duke of Richmond and Lennox.

The country around Richmond is extremely picturesque, and affords several objects of interest to the tourist and the antiquary. Close to the town, on the north, are the remains of a house of Grey friars, which was founded, in

1258, by Ralph Fitz-Randal, lord of Middleham; and adjoining is the site of a nunnery, now totally demolished. About a mile to the eastward are the fine ruins of St. Agatha abbey, seated on the banks of the river Swale. This monastery was established, in 1151, by Roaldus, constable of Richmond castle, and at the time of the reformation maintained seventeen monks of the Premonstratensian order. Richard Scroope, chancellor of England, was a great benefactor to this monastery; for besides his manor of Brumpton-upon-Swale, he granted 150*l.* a-year for the support of ten additional regular canons, two secular canons, and twenty-two poor men. Near this priory stood an hospital, which being decayed in the reign of Henry VI. was restored by William Ayseough, one of his judges, to whom he had given the patronage of it. A cell for Benedictines, dependent on the abbey of St. Mary of York, was situated on an eminence in this neighbourhood. It was founded, in 1100, by Wymer, chief steward to the earl of Richmond. Many other religious foundations occupied the banks of the Swale, which our limits forbid us to enumerate. The circumstance of the waters of this river having been held sacred, on account of the baptism of 10,000 Saxons near Catterick, by bishop Paulinus, in 627, gave occasion to this multiplicity of religious foundations. Catterick is situated at the distance of five miles from Richmond; and is supposed by several antiquaries to be the site of the Roman Cataractonium, or Cataracton, mentioned in the Itinerary of Antoninus. Dr. Gibson, however, supposes that station stood between the village and the river, and some extensive Roman remains, on the spot, he describes, seems to justify his conjecture. This station continued for some time a Saxon town; but was totally destroyed at an early period by the Danes. The Roman road here divides itself into two branches, one of which leads to Caldwell, distant about eight miles from Richmond, where vestiges of a large town may yet be traced. The Roman name of this station is unknown. A Tour in Scotland 1772, by Thomas Pennant, esq. 4to. Lond. 1790. Beauties of England and Wales, vol. xvi. by John Bigland.

RICHMOND, a village and parish in the hundred of Kingston, and county of Surrey, England, is situated on the south bank of the river Thames, at the distance of ten miles W.S.W. from St. Paul's cathedral, London. It is a spot of great celebrity, both on account of the beauty of its scenery, as well as from having been the site of a royal palace during several centuries. The first authentic mention of the manor here occurs in the reign of king John, at which time it was denominated Sheen, and was the property of Michael Belet, who held it by the service of being the king's butler. In the reign of Edward I. it reverted to the crown, and has since been generally possessed either by the king, or some branch of the royal family. At what precise period the original royal palace was erected is uncertain; for though Edwards I. and II. resided for some time in the manor-house, it does not appear to have been a structure entitled to that appellation. Edward III. is said to have built a palace on his "manor of Shene;" but Manning, the author of the "History and Antiquities of Surrey," inclines to the opinion, that he only improved and enlarged the former building. Be this as it may, it had undoubtedly become a fixed regal residence in the reign of that monarch, who died here the 21st of June, 1377; as did queen Anne, the consort of his successor, Richard II. in the year 1394. The latter prince was so much affected by his loss, that he abandoned the palace, and suffered it to fall to ruin; or, as others assert, pulled it down. From this period Sheen remained in a neglected state, till the accession

## RICHMOND.

of Henry V. to the throne, when the palace was rebuilt in a style of greater magnificence than before, and in such a manner, as to render it "a delightful mansion of curious and costly workmanship, and befitting the character and condition of a king." Of Henry VI. we discover no trace here, nor does it appear that Edward IV. ever occupied the palace; but it is recorded, that he granted it, in the sixth year of his reign, to his queen, Elizabeth, to be held by her during her life. Henry VII. gave the custody of the manor to Robert Skeene; and on the death of his own mother-in-law, the queen dowager, in 1486, took possession of the palace, which he frequently made his residence. In 1492 he held a grand tournament here, at which sir James Parker, in a controversy with Hugh Vaughan, for right of coat of armour, was killed in the first course. Seven years subsequent, the king being then at the palace, it was set on fire by accident, and almost totally destroyed. Henry, however, soon replaced it by another, which was built in a style of much "magnificence and elegance;" and on this occasion changed the name of the manor to Richmond, in reference to his own title before he obtained the crown. The picture of Henry V. and his family, the marriage of Henry VI. and that of Henry VII. in the Strawberry-hill collection, are supposed to have been painted for this monarch, and intended for the palace of Richmond. It had been finished only a short time, when another fire broke out, which did considerable damage. One of the newly erected galleries also fell in the same year, only a few minutes after the king and his son had been walking in it. Philip I., king of Spain, was entertained here with great magnificence in the year 1506; and king Henry VII. died here 21st April, 1509. His successor kept his Christmas at Richmond the year succeeding his accession to the throne; and on the 12th of January ensuing a tournament was held in the park, when the monarch himself, for the first time, took a part in the exercises. Charles V. was lodged at Richmond in the year 1523. King Henry VIII. had a son of his own name born here, who died when scarcely two months old. Queen Elizabeth was imprisoned in the palace by her sister, queen Mary; and after she was seated on the throne, it became one of her favourite places of residence. In her reign, Eric IV., king of Sweden, was lodged here, and here she herself ended her days, on the 24th of March, in the year 1603. In the autumn of the same year the several courts of justice were removed hither from London to avoid the plague, which was then raging with great vehemence in the capital. Henry, prince of Wales, resided here in 1605, and in 1625 the courts were a second time adjourned to Richmond for the same reason as before mentioned. Charles I. was frequently at this palace, where he formed a large collection of pictures. In 1636 lord Buckhurst, and lord Edward Sackville, performed a mask before his majesty and his royal consort. When the same monarch was in Scotland, the parliament ordered that the young prince should be sent to Richmond with his governor, probably bishop Duppa, who is said to have educated Charles II. at this place. In the month of June, 1647, the palace was prepared for the king's reception, but he is generally stated to have refused to go to it. Mr. Lysons, however, quotes a newspaper of the 29th of August in that year, as mentioning that the prince elector was then at Richmond, and that the king, with the duke of York, hunted in the New Park, and killed a stag and a buck. During the commonwealth, the palace was sold by the commissioners of the house of commons, who ordered a survey of it to be taken, as it then existed. From this document we learn,

that the great hall measured 100 feet in length, and 40 in breadth; and that it had a screen at one extremity, and a turret or clock-case, covered with lead, at the other. The same record describes the privy lodgings as a free-stone building, three stories high, and furnished by fourteen turrets. A "canted tower," with a staircase of 124 steps, is likewise noticed; also a chapel 96 feet long, and 40 broad; and a privy garden, with an open gallery 200 feet in length, over which was a close gallery of the same extent; but no mention is made of a library, though a French writer asserts, that a royal library was established at Richmond by Henry VII. and the librarian is enumerated among the officers of this palace in the household establishments of queen Mary and queen Elizabeth. The survey further mentions three pipes, which supplied the palace with water, one from the white conduit in the New Park, another from the red conduit in the town-fields; and a third from a conduit near the alms-houses, which are situated close to the river. The materials of the palace are there valued at 10,782*l.* 19*s.* 2*d.* It was purchased by Thomas Rookefsy, William Goodrick, and Adam Baynes, on behalf of themselves and other creditors, and shortly after sold by them to sir George Norton, who had been one of the commissioners appointed to sit in judgment on Charles I. On the restoration, this gentleman having been deprived of his estates by confiscation, Richmond palace was bestowed on the queen mother, but it is probable, that at this period it was in a very dismantled state. Indeed Fuller, who wrote soon after the restoration, speaks of it as pulled down; but this could not literally be the case, as it seems to have been inhabited subsequent to his day. Now, however, it is totally demolished, except a few of the out-offices, and its site is occupied by several houses, which are held on lease from the crown. One of these, the property of the late duke of Queensberry, was built by the third earl of Cholmondeley, who ornamented it with a very fine collection of pictures. The tapestry, which hung behind the earl of Clarendon in the court of chancery, still decorates the hall of this mansion. The first mention made of a park at Richmond is in the reign of Edward I. This is the park which, in the time of Henry VIII. was called the Old or Great Park, in contradistinction to another adjoining, called the New Park, which had been formed by the predecessor of that monarch. The lodge belonging to it was for some months the residence of the celebrated cardinal Wolfey, after he had lost the favour of his capricious and tyrannical master. Charles I. having formed a third park of far greater extent than both the former ones united, they appear to have merged into one soon after, as in the survey taken in 1649, only two parks are mentioned, *viz.* that lately inclosed by the monarch, called the New Park, and another styled the Little or Old Park. This last was valued at 220*l.* 3*s.* *per annum*, and was purchased by William Brome of London for 7048*l.* The lodge already mentioned was afterwards possessed by sir Thomas Jervase, and the park by sir John Trevor, in lease from the crown, to which the whole manor reverted at the restoration. King William afterwards granted the lodge, together with the stewardship of the manor, to John Latton, esq., who held them till the death of that prince. In 1707, they were granted by queen Anne to James, duke of Ormond, who rebuilt the lodge, and resided there till his attainder in 1715, when he privately withdrew to Paris. By act of parliament, passed in 1721, the earl of Arran, his brother, having been enabled to purchase his estates, king George II., then prince of Wales, bought this of Richmond from him, and frequently retired hither, even after his accession to the throne.

throne. His queen, Caroline, was very partial to the spot, and had a dairy and menagerie here; several ornamental buildings were also dispersed by the same princess throughout the gardens, in one of which, called the Hermitage, she placed the busts of Newton, Locke, and other eminent literary characters. His present majesty frequently resided here in the early part of his reign; and was so strongly attached to the place, that he ordered the old lodge to be demolished with the view of building a magnificent palace on its site, which, however, has never risen above the foundation; but an observatory has been erected at a short distance from it, according to designs furnished by sir William Chambers. Here is a mural arc of 140 degrees and eight feet radius; a zenith sector of twelve feet; a transit instrument of eight feet; and a ten-foot reflector by Herschel. On the top of the building is a moveable dome, which contains an equatorial instrument. Part of the Old Park forms a grazing and a dairy farm in his majesty's own occupancy. The remainder constitutes the royal gardens, which were first laid out by Bridgeman, and afterwards altered to their present improved state by Brown. The other park, *viz.* the New or Great Park, made by Charles I. met with great opposition to its formation, and may be reckoned among the impolitic measures of his reign. It was presented to the common council of London by the parliament; but was restored to the crown in 1660. The rangerhip of this park is considered an office of high dignity and trust, and has been frequently held by a female branch of the royal family.

Within Richmond parish were anciently situated several religious houses. Edward II. founded here a convent of Carmelite friars, and endowed it with an annual income of 120 marks out of his exchequer; but only two years after its establishment he removed the monks to Oxford. Henry V. also founded here a house for the maintenance of friars of the Carthusian order, whom he incorporated by the name of the House of Jesus of Bethlehem, at Shene. The foundation charter describes it as built on the north side of the palace; and it appears from records to have been a structure of great extent and magnificence. At the dissolution its annual revenues were estimated at 96*l.* 11*s.* 6*d.*, and shortly after its site was granted to Edward, earl of Hertford. A third convent was erected here by Henry VII. about the year 1499, and filled with friars of the Franciscan order. This establishment was suppressed in 1534, but its value is not recorded.

Richmond church is dedicated to St. Mary Magdalen, and consists of a nave, two aisles, and a chancel, built of bricks, with a square embattled tower at the west end, constructed of stone and flints in chequers. The principal monuments here are those of Henry, lord viscount Brounker, cofferer to king Charles II.; admiral Holborn; sir Matthew Decker; lady Chaworth, relict of sir Richard Chaworth, who died in 1689; lady Howard, relict of William lord Howard of Escrick; James Thompson, author of the "Seasons;" and that of Mrs. Yates, the celebrated actress, who died in 1787. This church is in the diocese of Winchester, and in the deanery of Ewell. According to the parliamentary returns of 1811, the parish contains 875 houses, and 5219 inhabitants. History and Antiquities of the County of Surrey, by the late Rev. Owen Manning, S.T.P. continued by William Bray, esq. of Shire, fol. vol. i. 1804. Salmon's Antiquities of Surrey, 8vo. 1732. RICHMOND, a township of America, on the W. line of Massachusetts, in Berkshire county; 17 miles W. by S. from Lenox, and 150 W. of Boston. Iron ore of the

best quality is found here; but as it lies deep, it is raised at a great expence. It abounds with lime-stone, and coarse, white, and clouded marble. It was incorporated in 1775, and contains an iron-work, three grist-mills, a fulling-mill, two saw-mills, with 1041 inhabitants.—Also, a township of Cheshire county, New Hampshire, on the Massachusetts line, about 11 miles E. of Connecticut river, and 97 W. by S. from Portsmouth. It was incorporated in 1752, and contains 1290 inhabitants.—Also, a township in Washington county, Rhode island, separated from Hopkington on the W. by Ward's river, a branch of Paucatuck river. It is distant about 19 miles W. of Newport, and contains 1330 inhabitants.—Also, a county of New York, comprehending the whole of Staten island; which see.—Also, a county of North Carolina, in Fayette district, bounded S. by the state of South Carolina, and N. by Moore county. It contains 6695 inhabitants. The chief town is Rockingham. The S.E. part of the county is a continued plain, covered in many places by pines, and mostly inhabited by Scotsmen. The upper part has hills and vallies. In the middle and east parts large tracts remain uncultivated. The inhabitants, with regard to religion, are Presbyterians, Baptists, Methodists, and Quakers. Their houses are logs, covered with slabs.—Also, a county of Virginia, bounded N. and N.E. by Westmoreland, and S. and S.W. by Rappahannock river, which separates it from Essex county. It contains 6214 inhabitants. The court-house is 273 miles from Philadelphia.—Also, the present seat of government of the state of Virginia, situated in Henrico county, on the N. side of James' river, at the foot of the falls, and containing between 400 and 500 houses; built partly on the bank of the river so as to be convenient for trade, and partly upon an eminence that overlooks the lower part of the town, and commands an extensive prospect of the river and country. The new houses are well built, and the state-house is on the hill. In this town is an elegant statue of the illustrious Washington, executed at Paris. The lower part of the town is divided by a creek, over which is a convenient bridge. Another bridge of curious construction connects the city with Manchester. The public buildings, besides the state-house, are an episcopal church, a court-house, gaol, theatre, and three tobacco warehouses. At the W. end of the town are several mills. Near the mills are a distillery and brewery. The falls above the bridge are seven miles in length. A noble canal is cut on the N. side of the river, which terminates in a basin of about two acres, in the town of Richmond. Richmond is 626 miles from Boston, 374 from New York, 176 from Baltimore, 278 from Philadelphia, 247 from Fayetteville, 497 from Charleston, and 662 from Savannah. N. lat. 37° 40'. W. long. 77° 50'.—Also, a county of the upper district of Georgia, in which is situated the city of Augusta; it is separated from South Carolina on the E. by Savannah river, and contains six towns and 6189 inhabitants.—Also, a township in Chittenden county, Vermont, established in 1794: it contains an excellent tract of land, and lies on both sides of Onion river. It has 935 inhabitants.—Also, a town, or rather village, in the island of St. Vincent, in the West Indies; situated at the head of a deep bay, on the W. side of the island. Chateaubelair river runs on the S. side of the town, which gives name to the bay. Another river on the N. side of the town empties into the bay.—Also, a township in Lenox county, Upper Canada, N. of Frederickburgh in the bay of Quinte, and watered in front by the river Appennie.

RICHMOND Bay, a bay on the N. coast of the island of St. John, in the gulf of St. Lawrence.

**RICHOLD**, or **RICHELD**, a town of France, in the department of the Rocr, near the Meuse; two miles N.W. of Dalem.

**RICHTENBERG**, a town of Anterior Pomerania; 28 miles E.N.E. of Rostock. N. lat. 54° 11'. E. long. 12° 50'.

**RICHTENSWYL**, a town of Switzerland, situated on the W. side of the lake of Zurich, in the canton of Zurich, with a convenient harbour; 11 miles S. of Zurich.

**RICHTER**, **FRANCIS-XAVIER**, in *Biography*. There are six musicians, male and female, recorded in Gerber's Continuation of Walther's Lexicon; among whom, the most celebrated and best known in England was Francis-Xavier, whose works, of various kinds, have great merit. His harmony is correct; and the subjects are often new and noble; but his detail and manner of treating them are frequently dry and sterile, and he spins and repeats passages in different keys without end. The French and Italians have a term for this tediousness, which is wanting in our language, they call it *rosalie*, or *rosalia*; derived from the name of a female saint, remarkable for repeating her "Pater noster," and stringing her beads more frequently than even St. Dominic himself, or than any other pious person, that has merited a place in the Golden Legend. An Italian cries out, upon hearing a string of repetitions, either a note higher, or a note lower, of the same passage or modulation, *ah santa Rosalia!* Indeed this species of iteration indicates a want of invention in a composer; as much as flammering and hesitation imply a want of wit or memory in a story-teller. He died at Strasburgh in 1789, in the 80th year of his age.

**RICIMER**, count and patrician of the Western empire, and an important civil and military character in the fifth century, served from his youth in the Roman armies, in which he acquired great reputation by his warlike exploits, and at length came to be regarded as the ablest commander of the age. In the reign of the emperor Avitus, being one of the chief commanders of the Barbarian troops which formed the defence of Italy, he destroyed, in the year 456, on the coast of Corsica, a fleet of Genseric, the Vandal king, destined to ravage the coasts of Gaul or Italy. His success in this instance enabled him to avail himself of the public discontent to depose Avitus, and raise Majorian to the throne in the year 457. Not being raised to the dignity which he expected under this prince, he compelled him to abdicate the purple, which act was soon followed by his death. Ricimer next raised an obscure man, named Libius Severus, to the throne, who bore the title of emperor during four years without performing any one imperial function. In that period, and in an interregnum of two years more, Ricimer exerted sovereign authority, amassing treasures, forming a separate army, and negotiating alliances. His own mean birth prevented him from assuming the purple, and in 467 he concurred in the inauguration of Anthemius, whose daughter he married. The new emperor and his son-in-law passed some years in union, but at length dissensions broke out between them, which ended in the murder of the emperor, and Olybrius was proclaimed in his stead. Thus a third, or perhaps a fourth, emperor was added to the number of Ricimer's victims; but in a few weeks after the massacre of Anthemius, "Italy," says Gibbon "was delivered by a painful disease from the tyrant Ricimer, who bequeathed the command of his army to his nephew Gundobald, one of the princes of the Burgundians." Gibbon's Rom. Hist. vol. vi.

**RICINA**, in *Ancient Geography*, an island situated on the coast of Hibernia, being one of those called Ebudes, according to Ptolemy and Pliny.—Also, a town of Italy, in the Picenum, which became a Roman colony under the reign of the emperor Severus. It was situated S.W. of Auximum.—Also, a town of Italy, in Liguria, S.E. of Genoa.

**RICINOCARPODENDRON**, compounded of *ricinus*, καρκινος, *fructus*, and *δενδρον*, *arbor*, in *Botany*, the name of a genus of plants, established by Dr. Amman, the characters of which are these: the flower is of the rosaceous kind, consisting of three petals, disposed in a circular order, in the centre of which there arises a large and open tube, through which shoots up the pistil, which grows at the bottom of the cup; this pistil, finally, becomes a trigonal fruit, divided into three cells within, and containing each one seed in a rough coat.

The leaves of this tree sometimes resemble those of the ash, being composed of three or four pairs of smaller leaves joined to a middle rib, these are not serrated, and terminate in a sharp point; the flowers grow at the axæ of the leaves, they are white, and are disposed in lax spikes; the fruit is green at first, afterwards it becomes of a yellowish-red, and finally scarlet; it is of the bigness of a walnut, and in shape much resembles the fruit of the ricinus; the covering of the seeds is black on the outside, and red within, and each seed is divided into two lobes; when ripe, the fruit bursts, and the seeds fall out. It is a native of the East Indies. A&C. Petropol. vol. iii. p. 214.

**RICINOCARPOS**, from the resemblance of the fruit to *Ricinus*. See ACALYPHIA, CROTON, MERCURIALIS, TRAGIA.

**RICINOIDES**. See CEANOTHUS, CROTON, JATROPHA.

**RICINUS**, so denominated from the resemblance its seed has to the little insect called a tick, *Ricinus*; and this, according to Ainsworth, is compounded of *re* and *canis*, because the tick, or tyke, is particularly annoying to dogs, by fixing itself upon their ears and other parts. It is the *Κικινος* or *Κικιστον* of Dioscorides, words expressive of the likeness of its seed to the above-named insect; the former of these appellations, however, is of eastern origin, and of rather uncertain signification, occurring in the prophet Jonah. Pliny mentions an Egyptian herb called *Palma-Christi*, with seeds like a tyke.—Linn. Gen. 503. Schreb. 655. Willd. Sp. Pl. v. 4. 564. Mart. Mill. Dict. v. 4. Ait. Hort. Kew. v. 5. 331. Pursh v. 2. 602. Tournef. t. 307. Juss. 388. Lamarck Dict. v. 6. 200. Illustr. t. 792. Gærtn. t. 107. Loureir. Cochinch. 584.—Class and order, *Monocotyledon Monadelphica*. Nat. Ord. *Tricoccoæ*, Linn. *Euphorbia*, Juss.

Gen. Ch. Male, *Cal.* Perianth inferior, of one leaf, cloven into five, ovate, concave segments. *Cor.* none. *Stam.* Filaments very numerous, thread-shaped, united unequally below into various sets; anthers twin, roundish.

Female on the same plant with the male, *Cal.* Perianth inferior, of one leaf, deciduous, cloven into three, ovate, concave segments. *Cor.* none. *Pist.* Germen superior, ovate, covered with awl-shaped bristly bodies; styles three, cloven, erect and spreading, hispid; stigmas simple. *Peric.* Capsule roundish, three-furrowed, generally prickly all over, of three cells and three valves. *Seeds* solitary, nearly ovate.

Eff. Ch. Male, Calyx five-cleft. Corolla none. Stamens numerous. Female, Calyx three-cleft. Corolla none. Styles three, cloven. Capsule three-celled. Seed solitary.

## RICINUS.

Obf. Willdenow divides this genus into two sections; the first containing such species as have *palmate leaves*, the second those which have simple, *undivided leaves*.

### SECT. 1. *Leaves palmate.*

1. *R. communis*. Common Palma-Christi, or Castor-oil Plant. Linn. Sp. Pl. 1430. Woodv. Med. Bot. 171. t. 61.—Leaves peltate; lobes lanceolate, ferrated. Stem herbaceous, pruinose. Stigmas three, cloven at the tip.—Native of the East and West Indies. First cultivated in England, as appears from Turner's Herbal, in 1562. It flowers in July and August. *Root* biennial or annual, long, thick, and fibrous. *Stems* round, thick, jointed, channelled, glaucous; of a purplish-red colour upwards. *Leaves* large, deeply divided into seven segments, on long, tapering, purplish stalks. *Flowers* in long, green, and glaucous spikes, springing from the divisions of the branches; the males form the lower part of the spike, the females the upper. *Seeds* ovate, shining, black dotted with white.

The present species is subject to considerable variations. In our gardens it is a strong, luxuriant, shrubby annual. In Africa it becomes a tree. Clusius observed it in Spain, with a trunk as large as a man's body, and fifteen or twenty feet high. And Ray saw it in Sicily as big as our common Elder-trees, woody and long-lived. From the seeds of this valuable plant is extracted the *oleum ricini*, or castor-oil, so important for its medicinal properties as a gentle, though most effectual, cathartic.

2. *R. viridis*. Green Palma-Christi. Willd. n. 2. Hort. Berol. v. 1. t. 49.—Leaves peltate; lobes oblong, toothed, the middle one slightly three-lobed. Stem herbaceous, pruinose. Stigmas six.—Native of the East Indies, flowering at Kew, in August. Very like the last, but always annual, with a taller and somewhat less pruinose stem. *Leaves* larger, and not so distinctly palmate.

3. *R. africanus*. African Palma-Christi. Willd. n. 3. (*R. communis*; Desfont. Atlant. v. 2. 355.)—Leaves peltate; lobes oblong, ferrated. Stem shrubby, smooth.—Native of the north of Africa. *Stem* arboreous, or rather shrubby, not pruinose. *Leaves* smaller than in the preceding. *Stigmas* six, or more properly three, cloven down to the base.

4. *R. lividus*. Dark-leaved Palma-Christi. Willd. n. 4. Jacq. Ic. Rar. t. 196. Misc. v. 2. 360.—Leaves peltate, coloured; lobes oblong, ferrated. Stem shrubby, smooth, coloured.—Native of the Cape of Good Hope, whence it was introduced at Kew in 1795. *A tree* ten feet or more in height. *Stem*, during the first year, blood-red and shining, afterwards woody and thick, ash-coloured and streaked. *Leaves* divided into eight or ten lobes, of a dark blood-red colour, on long, glandular stalks. *Flowers* green. *Fruit* of a livid colour, with long, soft prickles. *Seeds* shining, variegated with black and brown.

5. *R. inermis*. Smooth-fruited Palma-Christi. Willd. n. 5. Jacq. Ic. Rar. t. 195. Misc. v. 2. 362.—Leaves peltate; lobes oblong, ferrated. Stem shrubby, pruinose. Capsules without prickles.—Native both of the East and West Indies. In habit much resembling the last, but altogether flouter. *Stem* brown, spotted with dark purple. *Leaves* very large, on long stalks. *Fruit* ovate, rugose, dark green.

6. *R. speciosus*. Beautiful Palma-Christi. Willd. n. 6. Burman. Ind. 207. t. 63. f. 2.—Leaves peltate, inclining to digitate; leaflets lanceolate, ferrated.—Native of Java. We know not that this is any where described or figured, except as it occurs in the above authors.

### SECT. 2. *Leaves simple, or undivided.*

7. *R. Tanarius*. Scollop-leaved Palma-Christi. Linn.

Sp. Pl. 1430. (*Tanarius minor*; Rumph. Amboin. v. 3. 190. t. 121.)—Leaves peltate, ovate, pointed, wavy, toothed.—Native of the East Indies, and woods of CochinChina. It flowers at Kew, from July to September. *A middling sized tree*, with twined, spreading branches. *Leaves* on long stalks, scattered, fragrant. *Flowers* in long, simple, terminal clusters.

8. *R. dioicus*. Dioecious Palma-Christi. Willd. n. 8. Forst. Prodr. 67.—Leaves heart-shaped, pointed, nearly entire. Flowers dioecious. Capsules muciated.—Native of Tanna island. This shrub has round, smooth, brown branches, the younger ones white with down. *Leaves* alternate, entire, or very obscurely toothed; smooth above with downy veins; reflexed and dotted beneath. *Female flowers* in small, axillary, stalked clusters. *Bractea* solitary, ovate, pointed, very large, at the base of every flower.

9. *R. globosus*. Globular Palma-Christi. Willd. n. 9. (*Croton globosum*; Swartz Ind. Occ. v. 2. 1181.)—Leaves ovate, obtuse, entire. Flowers dioecious. Capsules globular.—Native of lofty mountains in Jamaica. *A branched, erect shrub*, four or five feet high. *Branches* round, striated, ash-coloured. *Leaves* alternate, stalked, coriaceous. *Flowers* in terminal, short, erect clusters. *Capsule* roundish, the size of a pea.

10. *R. integrifolius*. Simple-leaved Palma-Christi. Willd. n. 10.—Leaves ovate, pointed, entire, coriaceous.—Native of the Mauritius. Adopted solely on Willdenow's authority, who describes it as "a shrub with round, brown, smooth, divided branches. *Leaves* smooth, on channelled stalks two or three inches long. *Clusters* axillary. *Flowers* and *Fruit* unknown. It appears to be dioecious."

RICINUS, in Gardening, contains plants of the tall, herbaceous, tender, annual kind, of which the species cultivated is the common palma-Christi (*R. communis*).

This plant becomes a tree in its native situation, and the seeds afford the castor-oil of the shops.

And there are several varieties of it, as the great American palma-Christi, which has brown stalks that divide into two or three branches, and rise six or seven feet high; the leaves are broader, and not so deeply divided; they are of a deep green on both sides, and are unequally ferrate. The spikes of flowers are shorter, the seed-vessels rounder and of a brownish colour, and the seeds are much less, and brown. This sort is a native of the West Indies.

Also the green-stalked American palma-Christi, which has a thick herbaceous stem, of a greyish-green, with the joints not so far asunder as in the preceding sort: it rises about four feet high, and is divided at the top into three or four branches, which spread out almost horizontally; the leaves are large, of a deep green on their upper side, but greyish on their under; they are deeply cut into six or seven (sometimes eight) lanceolate segments, which are unequally ferrate: the petioles spread out more horizontally than those of the common sort, and are much shorter: the principal stalk and branches are terminated by loose spikes of flowers; the covers of the capsules are green, and closely armed with soft spines; the seeds are smaller and lighter coloured than those of the preceding sort. This is also a native of the West Indies.

Likewise the wrinkled-capsuled palma-Christi, which rises with an herbaceous stalk about four feet high; the lower part is purplish, and the upper deep green, the joints pretty far asunder; the leaves are of a deep green on their upper side, but paler underneath; they are not so deeply divided as some of the others, and are more regularly ferrate; the spikes of flowers are large; the males have more stamens, with yellow anthers; the capsules are oval and wrinkled,

but have no prickles; the seeds are small and brown. This is a native of both the Indies.

Farther, the red-stalked palma-Christi, which rises with a large reddish stalk to the height of ten or twelve feet, with many joints, and dividing into several branches; the leaves are very large, some measuring more than two feet and a half in diameter; are of a dark green, unequally ferrate, and not so deeply cut as in some of the varieties; the spikes of flowers are large, and brown, with whitish anthers; capsules large, oval, and closely set with soft prickles; the seeds are very large, and beautifully striped. This sort is a native of Africa and both the Indies.

And the small American palma-Christi, of which there are two sub-varieties, one with a red, the other with a pale-green stalk, distinguished in America by the names of red and white oil-seed; the stem seldom rises more than three feet high, sometimes dividing at the top into two or three branches; the leaves are much smaller and more deeply divided than in the other varieties; their borders are unequally ferrate, and the segments of the leaves are frequently cut on the sides; the spikes of flowers are smaller and more compact; the capsules are also smaller, rounder, of a light green, and closely set with soft prickles; the seeds small, and finely striped. This is a native of Carolina, and some other places.

Lastly, the livid leaved palma-Christi, which is an ever-green tree, ten feet in height, and more; the trunk, during the first year, is blood-red and very shining; afterwards it becomes woody, as thick as the wrist, hollow with transverse septa, pithy, with circular warts at the joints from fallen stipulas, ash-coloured, interruptedly and slightly streaked: before the leaves come out, they are wrapped up in red stipulas like sheaths, that fall off soon after; the leaves are divided half way into eight, sometimes ten lobes, which are ferrate and acute, and the petiole is long; they are of a dark blood-red colour on the upper surface, and livid on the lower, with blood-red veins, the largest less than a foot in diameter, quite smooth, without any hairiness whatever; the fruit of a livid colour, with long soft prickles; the seed shining, variegated with black and brown. This is a native of the East Indies.

*Method of Culture.*—All these sorts of plants are capable of being increased by seeds, which should be sown upon a hot-bed in the spring, and when the plants are come up, be each planted into a separate pot filled with light fresh earth, and plunged into a fresh hot-bed, watering and shading them until they have taken root; after which they must have a great share of free air when the season is mild, otherwise they draw up tall and weak. As the plants grow fast, and their roots in a short time fill the pots, they should be shifted into larger pots, filled as above; and about the end of May, when the season is warm, be hardened to endure the open air by degrees; when, if some of the plants be shaken out of the pots, and planted out into a very rich border, and in dry weather duly watered, they grow to a large size, and produce a great quantity of flowers and seeds. If it be intended to preserve any of the plants through the winter, they must not be planted out in the full ground, but be shifted into larger pots occasionally, as their roots require, placing them in the open air during the summer season in some warm situation, where they may remain until October, when they must be removed into the green-house with other exotic plants, watering them sparingly in winter, and admitting free air in mild weather, as they only require to be protected from frost and cold winds.

In common, they have a fine ornamental effect in their leaves among other potted green-house plants, and also in

the large open border or clumps, when cultivated as annuals; but they require room.

*RICINUS Communis*, or common Palma-Christi, in the *Materia Medica*. See *CASTOR Oil*.

*RICITOSA*, in *Geography*, a town of Moldavia; 20 miles W. of Birlet.

*RICK*, in *Rural Economy*, a term applied to a pile of corn, hay, straw, &c. regularly heaped up in the open air, and sheltered from wet by thatch. See *STACK*, and *STAND, Corn*.

*RICK-Yard*, a term sometimes given to that part of the farm-yard in which the stacks are placed. They should be sufficiently large, well sheltered from winds, and perfectly secured from all sorts of vermin, especially rats and mice.

*RICKBAD*, in *Geography*, a town of Hindoostan, in Oude; 20 miles N.W. of Lucknow.

*RICKETS*, in *Medicine*, a disease affecting children, and principally characterized by enlargement and flexure, or distortion of the bones.

The origin and etymology of this word are equally unknown. It has occurred in this, as in several other instances, that the vulgar had recognized and given a name to the disease, before medical men had discriminated its nature, or at least had taken the pains to point out its peculiarities by any written document. The first account of the disease is that of Dr. Glisson, published in the year 1650, which was the result of some communications on the subject in a private medical society. In this treatise we are informed, that the *ricketts* had first been noticed in the counties of Dorset and Somerset, about thirty years before, where it was vulgarly known by this name, and that it spread from thence over all the southern and western parts of the kingdom, but was not yet commonly known in the north. The rapidity of its progress, and the extent and fatality of its prevalence, are scarcely less extraordinary than its general and speedy disappearance in later times, as no assignable cause has ever been pointed out either for its origin or its cessation. Its first appearance, as a cause of death, in the bills of mortality of London, was in the year 1634, when the total number of deaths under this head was only 14; but an extraordinary increase soon took place. For, in 1649, the deaths from rickets amounted to 190; in 1650, to 260; in the following year, to 329; and in 1660, 521 persons died of this disease. At the commencement of the 18th century, the mortality from this disorder was 393 (A. D. 1700); and it subsequently decreased rapidly; for in the year 1750, the number of deaths, recorded in the bills under the head of rickets, is only 21; and at the end of the century (1799), the deaths, under the head of "evil and rickets" conjoined, do not exceed 7. (See *Ann. Medical Register*, vol. i. for 1808, p. 324.) At present, indeed, the disease is almost unknown to medical practitioners, except by name.

With the view of accommodating a classical name both to the vulgar appellation and to the symptoms of the disease, Glisson invented the term *rachitis*, *ραχιτις*, i. e. *spinal disease*; since the curvature of the spine, which ensues, is one of the most prominent symptoms. This appellation has been adopted by the nosologists, and all subsequent writers, who have used a Latin nomenclature. (See Glisson, de *Rachitide*, cap. i.) Whether the disease was really unknown, or did not exist, until modern times, is a question which it would be very unprofitable to discuss; since there are few satisfactory documents to be found on the subject. We shall therefore proceed to deliver a history of the symptoms.

This disease seldom commences before the ninth month, and rarely after the second year, of a child's age; but it may

## RICKETS.

may appear at any interval between these two periods. Its progress is at first usually very slow. The early appearances of its approach are a flaccidity of the muscular flesh, and a certain degree of emaciation of the body, notwithstanding that the appetite for food is rather increased than impaired; together with a paleness and loss of colour in the complexion, and a slight degree of fulness, or tumefaction in the face. The head at the same time appears large with respect to the body, and the fontanelle, and even the sutures of the skull, are more open than is usual in children of the same age. The head continuing to increase in size, the forehead especially, becomes unusually prominent, and the neck appears very slender in proportion to the head. The progress of dentition is also slow, or much later than usual; and those teeth which protrude themselves soon become black, decay, and often fall out. Their ribs lose their convexity, and become flattened at their sides, while the sternum, or breast-bone, is pushed forward, so as to form a sort of ridge. At the same time, or sometimes sooner, the epiphyses at the several joints of the limbs become swelled, while the limbs between the joints appear, or perhaps actually become, more slender. The bones now are obviously every where, to a certain degree, flexible, becoming variously bent and distorted, and especially the legs and the spine of the back are incurved in various directions. If the child had already acquired the power of walking before the commencement of the disease, it becomes daily more feeble in its motions, and more averse to exertion, and at length loses the power of walking altogether.

While these symptoms go on increasing, the abdomen always appears preternaturally full and tumid, and the stools are generally frequent and loose; yet the appetite often remains good. The faculties of the mind often exhibit a premature advancement, and the power of speech is early acquired; but in some cases the understanding is impaired, and stupidity or actual fatuity ensues. There is usually no febrile affection accompanying the disease at its commencement; but it seldom continues long before the pulse becomes frequent, and other symptoms of fever ensue.

With these symptoms the disease proceeds, and continues in some instances for several years; but, in many cases, in various stages of that progress, it ceases to advance, and the child gradually recovers its health and strength, except that the distortion of the limbs, produced by the disease, continues during the remainder of life. In other cases, however, the malady proceeds, continually increasing, until it has affected almost every function of the animal economy, by the derangement of the viscera and the impediment to their operations, which the distortion of the bones occasions. The most material danger and distress thus produced arise from the distortion of the spine, ribs, and sternum, by which the cavity of the chest is greatly diminished, and the action of the lungs and of the heart much impeded, or altogether arrested. The functions of the liver, stomach, &c. and those of the uterus and bladder, under distortions of the pelvis, are thus also often rendered morbid and distressful for the rest of life. When the head, too, is greatly enlarged, the existence of water is to be apprehended. It is unnecessary to enter into any detail of all the variety of symptoms, which are the secondary effect of these impediments to the action of particular organs; since relief is not to be obtained effectually while the mechanical impediment exists incurably, and the origin of each particular symptom will be easily explained from the circumstances of each case. The organs themselves, however, become seriously deranged under this state of pres-

sure and obstructions; and morbid conditions have been discovered in various parts internally in the bodies of those who have died. Thus, most of the viscera of the abdomen, the liver, spleen, and mesenteric glands, have been found to be preternaturally enlarged; the lungs have been found in a morbid state, apparently from some inflammation that had come on towards the termination of the disease. The brain has been commonly found in a flaccid state, with effusions of a serous fluid into its cavities. The bones very universally have been commonly found in a flaccid state, with effusions of a serous fluid into their cavities. The bones very universally have been found to be soft, so much so indeed, as to be readily cut by a knife; and the muscular parts also soft and tender, the whole of the dead body being without that degree of rigidity which is so common in almost all others. Cullen, First Lines, par. 1724.

The great peculiarity, then, of this disease, appears to consist in a deficiency of that matter which forms the solid parts of the body, especially of the bones, or in a faulty state of the process of ossification, by which that matter is deposited in the membranes and substances destined to become bony, to give them their due firmness, hardness, and strength. There is obviously a defect in the quantity of this matter, the place of which is supplied, especially about the epiphyses of the bones, by a soft substance which increases their bulk. What this deficiency of ossific matter depends upon, it is difficult to ascertain: it may originate either in the faulty action of the organs of digestion and assimilation, by which the nutritive fluids are prevented from being properly prepared; or from a fault in the organs of secretion and nutrition, which prevents the proper elaboration of the circulating fluids. Of the nature of this latter process, however, we are totally ignorant; and practitioners have more generally referred to the former, and ascribed the disease to the actual deficiency of bony matter in the circulating fluids, as furnished by the digestive organs: yet they have been generally also compelled to refer this deficiency to some general laxity or debility of the system. But admitting the existence of such a debility, it is altogether impossible to account for its operation in diminishing the ossific matter, being limited to the early portion of childhood; for though a *mollities ossium*, or softness and flexibility of the bones, has occurred in adult life, it is a circumstance of extreme rarity. In a word, the essential nature of the disease is beyond our investigation.

*Causes of Rickets.*—Neither are the causes of the disease very clearly demonstrated. Great stress was laid by the earlier writers upon the *hereditary* predisposition which descended from parents to their children; but the very rapid increase of the disease among children, soon after the disorder was first noticed, and therefore the necessary primary origin of it in many whose parents must have been free from the taint, renders the opinion untenable. Indeed the rise, prevalence, and disappearance of the disease, during a certain period of time, including about a century and a half, would seem to connect its existence with some more general cause; but no one has been able to point out any peculiar physical condition of the people of England, during that period, to which such a malady can be attributed. Some have imputed it to the multiplication of manufactures and other unwholesome occupations; but the manufactures continue while the disease has nearly vanished. It is certain, however, that in later times the disease has been principally known among the children of the poor, living in close and uncleanly situations, and in dirty ill-ventilated apartments; and especially among those children who are ill-nursed, that is, in whom constant washing and proper exercise,

exercise, as well as good feeding, have not been attended to. Damp air, and residence in a cold and humid situation, have also been enumerated among the predisposing causes of rickets; and in this respect, as well as in the practice of better modes of management in infancy, the change of circumstances in the present state of great towns, and even in the habitations of the peasantry, when compared with those of the preceding century, will be deemed sufficient at least to have greatly diminished the general sources of infantile disease and mortality. See HEALTH.

*Cure of Rickets.*—Observation of the circumstances under which the rickets occurred, as well as of those with which it was accompanied, suggested the only means that were resorted to for the cure of this disease, until modern chemistry proposed the administration of a substitute for the deficient ossific matter; a proposal, however, which does not appear to have led to the advantages which were anticipated. The method suggested from observation of the circumstances just alluded to, was rather of a preventive than of a curative nature; and turned upon the plan of invigorating the constitution of the infant from the period of its birth. This is to be accomplished by remedies which may improve the tone of the stomach in particular, and through that medium of the system at large, or by those which operate directly upon the latter. Of these general tonic remedies, the *cold bath* seems to have been commonly found to be the most effectual, at least as a preventive of the disease. Since it became a general custom in this country, through the recommendation of medical men, to wash young children with cold or tepid water daily, the rickets seem to have been less and less prevalent. Indeed Dr. Cullen declared long ago, that he had never met with the rickets where this practice was adopted; and that where the disease had already begun, this remedy often checked the progress of the disease, and sometimes cured it entirely.

With the same view internal medicines of a tonic quality have been generally prescribed, to remove or arrest the disease; and among these, the preparations of *iron* have been most frequently employed. A preparation of this kind was long ago recommended by Mr. Boyle, and universally adopted, under the appellation of *ens veneris*, which, notwithstanding its name, was iron. The rust of iron, and other preparations, as well as those of zinc, have been also used for the cure of rickets, in preference to the Peruvian bark, on account of the difficulty of administering this substance to infants in any useful quantity; De Haen, however, has borne testimony to the efficacy of the latter.

Much is also to be done by good nursing; that is, by a proper regulation of the exercise, diet, and clothing, by all of which the healthy performance of the functions of an infant is greatly assisted. Exercise, indeed, even in the only form in which young children can enjoy it, *viz.* that of gestation, is one of the most powerful general tonics; and even friction with dry flannels would probably contribute to the same end. The diet of children is now reduced to a much more rational standard than during the last century, and the proper mode of administering it is now too well understood to require any minute instructions in this place. (See INFANTS.) The supposition of the pernicious acidity, arising from the use of that most natural food milk, to which Zeviani and some other writers ascribed the origin of the disease, is altogether without foundation.

It is highly proper, also, where there is a ricketty tendency present, to attend to the symptoms which accompany its approach, and to correct any influence which these symptoms may have upon the general health. Above all, it is advisable to administer remedies against the derangements of

the abdominal viscera, connected with tumid abdomen and irregularity of bowels, which so commonly attend that disposition. For this purpose the testaceous powders, combined with small doses of some mercurial alterative, or with rhubarb, or the latter united with steel and soda, may be prescribed with benefit. The use of emetics, which was resorted to by some practitioners, appears to be of no beneficial tendency, unless they may act on the bowels as laxatives; and a system of active purging, which was also generally employed, as it contributes to much debility, should be avoided.

It remains only to mention the chemical proposal, which M. Bonhomme of Paris proposed, of administering the component parts of bone in the way of medicine, upon the supposition that the disease depends upon the mere deficiency of these substances in the circulating blood. M. Bonhomme therefore suggested the administration of phosphate of lime and phosphate of soda in substance; and formed a powder, consisting of equal parts of these substances, of which he gave a scruple twice a day to infants. He contends that the calcareous phosphate, when taken internally, is really transmuted by the lymphatic vessels, and is applied to the purposes of ossification, and that this administration of it powerfully contributes to restore the natural proportions in the substance of the bones, and thus accelerates the cure of rickets. In support of these opinions, he relates various experiments made on young fowls, to which it was given mixed with their food, and in which, he maintains, the progress of ossification was accelerated, in comparison with others to which it was not given. (See his Memoir on Rachitis; and Duncan's Annals of Medicine for 1797.) These physiological experiments, however, lead to no legitimate deductions as to the operations of disease in the human body; and, experience in the latter has not apparently supported the doctrines of M. Bonhomme.

RICKETS is also a disease affecting sheep, as well as some sorts of vegetable crops.

RICKETY GRAIN, in *Agriculture*, a sort of vegetable disorder that often attacks wheat crops. It is, according to Dr. Anderson, a kind of disease which is totally different from that of *smut* or *rust*. The grain affected with this disease assumes a small shrivelled appearance, and irregular form; its colour is somewhat darker than good wheat of the same kind, but is different from that which is affected with either of the two other diseases. Water, when poured upon wheat of this kind, soon, he observes, moistens it, and brings to life a number of eel-shaped animals in various stages of their growth, which had taken up their residence there while the grain was yet in its succulent state, and thus occasioned the disease which produced the alteration in its form. As the grain ripens and dries, these animalcules are arrested in their progress, their life totally suspended, and their destructive operations upon the corn of course obstructed, so long as it remains in this dry state. But no sooner does this grain become soft, in consequence of being moistened with water (whether after being sown in the ground or otherwise), than these creatures are restored to life and activity; they soon begin to feed upon the grain while it is moist, and, if not interrupted in their progress by another desiccation, quickly lay their eggs (for they are oviparous), and go through the ordinary evolutions of nature. The young, when hatched in the corn that was sowed, after living upon it for some time, begin, he asserts, to eat their way up the growing stalk, and establish themselves at length in the grain itself, while it is advancing towards maturity, where they are arrested in their progress in the manner above described when it is fully ripened.

And in respect to the nature of the animalcule that produces these effects, it is remarked, that it can be preserved alive in a quietest dried slate, for twenty-eight years at least, as has been shewn by experiment, after the lapse of which period it was found to revive as readily as if its vital functions had been thus suspended only for one day. It is further slated as worthy of remark, that the eggs of this creature cannot be preserved for a length of time in a dry slate, and still retain their prolificacy, neither can those among them which are very young, or those which have attained their full size, be revived after they have been dried up. It is only those individuals that are in the full vigour of life, and in a state soon to produce young, that are endowed with this singular faculty. In this case, the obvious intention of nature is to preserve the species, by keeping them in life until the grain shall be sown, and thus to have a proper food provided for their progeny, however long that may be.

RICKMAN, GEORGE WILLIAM, in *Biography*, a member of the Imperial Academy of Sciences at Petersburg, was born at Pernau in 1711, after the decease of his father, who was treasurer to the king of Sweden. Having acquired the rudiments of a good education in the gymnasium at Revel, he prosecuted his studies at the universities of Halle and Jena, but applied chiefly to mathematics and natural philosophy, to which he shewed a particular attachment. In the year 1735 he was made a member of the Imperial Academy of Sciences; in 1741 he became extraordinary professor, and in 1745 he was elected ordinary professor of experimental philosophy. He was from this period particularly attached to the new science of electricity, and applied himself particularly to atmospheric electricity. On the discoveries made in this branch of knowledge he had composed a treatise, which he intended to read on the 6th of September 1753, at a public meeting of the Academy; and in order to demonstrate what he might advance in the discourse, he made a great number of experiments on divers thunder clouds. In one of these the professor was struck dead by a flash of lightning, drawn by his apparatus into his room. Of this fatal accident there are two accounts in the Transactions of the Royal Society.

The professor had provided himself with a gnomon, an instrument to measure the strength of the electricity of the passing clouds. He was, on the 6th of August, N.S. 1753, a little before noon, at the Academy, when it thundered at a considerable distance, the sky being then clear and the sun shining bright. In the hope of confirming his former observations, or of making some new ones, he hurried home, accompanied by Solokow an engraver, that the latter might make himself master of the leading circumstances of the electrical experiments, in order to be the better enabled to represent it on a copper plate, which was to be annexed to his dissertation. The philosopher led the engraver to his apparatus, but while examining for his own use, or perhaps describing the effect of the electricity on the gnomon to his friend, with his head inclined towards it, he received a violent shock, which instantly deprived him of existence. M. Solokow observed, he said, a globe of blue fire, as big as his fist, jump from the rod of the gnomon towards the head of the professor, which was at the instant about a foot from the rod. This flash killed M. Rickman, but M. Solokow could give no account of the particular manner in which he was immediately affected by it; for, at the same time that the professor was struck, there arose a sort of steam, or vapour, which entirely benumbed him, and made him sink to the ground, so that he did not even remember to have heard the clap of thunder, which was very loud. The globe of

fire was, however, attended with a report as loud as that of a pistol: a wire, which brought the electricity to his metal rod, was broken in pieces, and its fragments thrown upon M. Solokow's clothes. Upon examining the effects of the lightning in the room, it was found that the door-case was half split through, and the door torn off and thrown into the room. An attempt was made to bleed the breathless body, but no blood followed. The shoe belonging to the left foot was burst open, and uncovering the foot at that place, they found a blue mark, from which it was inferred that the electrical fluid, having entered the head, made its way out again at the foot.

Upon the body were several red and blue spots, but the hair of the head was not singed. The stocking was entire though the shoe was ripped up; the coat was uninjured though the waistcoat was much singed; and there appeared on the back of M. Solokow's coat long narrow streaks, as if red-hot wires had burnt off the nap. On opening the body the cranium was entire, and the brain perfect, but the transparent pellicles of the windpipe were excessively tender, gave way, and were easily rent. There was some extravasated blood in it, as likewise in the cavities below the lungs; those of the breast being quite found, but those towards the back were of a brownish colour, and filled with more of the above-mentioned blood: otherwise none of the entrails were touched, but the throat, the glands, and the thin intestines, were all inflamed. After two days the body was in such a state of putrefaction that it was with difficulty got into a coffin. *Phil. Transf. vol. xlix. pt. 1. Priestley on Electricity.*

RICKMANSWORTH, or RICKMERESWORTH, in *Geography*, a small market-town in the hundred of Cashio and county of Hertford, England, occupies a low, moorish situation near the confluence of the rivers Gade and Colne, at the distance of 19 miles N.W. from London. The manor was an ancient demesne of the Saxon kings, and was given by king Offa to the abbey of St. Alban's, to which it was confirmed by succeeding monarchs, and had the charter of a weekly market and two annual fairs granted by Henry III. The church is a spacious edifice, consisting of a nave, aisles, and chancel: it was repaired in the year 1677, and again in 1802: the large gallery at the west end was probably erected about the former period. Previous to the late repairs, a large altar-tomb, in memory of Henry Cary, baron of Leppington and earl of Monmouth, stood against the south wall of the chancel; but being supposed to disfigure the place, it was removed; and a memorial slab of black marble, which was affixed to the tomb, was let into the south wall, with sculptures in white marble of the family arms. Against the north wall is a mural monument, to commemorate sir Thomas Fotherly (gentleman of the privy chamber to Charles I.), and his son and grandson. Several others of the family are recorded on a slab on the floor. In the east part of the south aisle are three large altar-tombs, in which are deposited the remains of the families of Colte, Salter, and Whitfield, inhabitants of this town. In the north aisle a neat mural monument records the memory of Timothy Earle, esq. of Moor-house, who died in May 1787, aged 80; and also of Dorothy his wife. A marble tablet against the north wall commemorates admiral William Bladwell, formerly of Money-hill in this parish, who died in March 1783, at the age of 80.

Rickmansworth, by the vicinity of several streams, is rendered very convenient for trades that require the assistance of water: several mills have consequently been erected for various purposes in its neighbourhood: a large cotton and flour-mill at the south entrance to the town; one for flock and

and filk at a small distance to the west; and several for paper, &c. towards the north, on the rivulet that flows from Chessham. Additional employment, particularly for females, is derived from the manufacture of straw-plat. The market was formerly distinguished for its corn trade, but is now little frequented, though toll free: the market-house is a mean wooden structure, raised on pillars, and open beneath. The population, as ascertained under the act of 1811, was 3230, the number of houses 589.

The manor of the *Moor* in Rickmanworth parish, being anciently parcel of the possessions of St. Alban's abbey, was, about the year 1431, with other contiguous manors, held under that foundation by a tenant named Flete, who had for several years refused either to pay the quit-rent, or to perform the covenanted services claimed by the abbot; one of which was finding for his use, and that of his successors, "one nag-horse to carry him to Tynemouth, whenever he or they should visit that cell:" the dispute was at length decided in favour of the abbot by Sir William Babyngton, chief justice of the common pleas; and Flete was compelled to the observance of the accustomed homage and fealty. The next possessor on record was Ralph de Boteler, lord of Sudely in Gloucestershire. It is now held by Robert Williams, esq. banker of London.

Moor-Park house, the splendid residence of this gentleman, is a magnificent building of the Corinthian order, standing in a finely wooded park about five miles in circumference, and having two fronts, respectively facing towards the north and south. The height of the ground to the south contracts the view; but the northern front commands an extensive prospect; the hill, which had previously obstructed the sight, having been lowered about the year 1725, at the expence of 5000*l.* This was effected by B. H. Styles, esq. to whom the present mansion is indebted for its chief grandeur, as he new-cased and fronted it with Portland stone; and having built the magnificent portico, erected two wings for the chapel and offices, and connected them with the centre by colonnades of the Tuscan order. The charge of the carriage of the stone from London, amounted to upwards of 15,000*l.*, and the entire expence, including the improvements in the park, was more than 150,000*l.* Beauties of England and Wales, vol. vii. by E. W. Brayley.

RICKSGÖLD, in *Commerce*, one of the two species of paper currency in Sweden, the other being *banco*. The latter is issued by the national bank, and the former by the Ricksgöld bank, which is under the direction of government. Banco is 50 per cent. better than Ricksgöld; that is, two dollars of the former are worth three dollars of the latter. Banco is a legal tender, and has lately been declared, by royal authority, the national currency. Ricksgöld is current in all payments; but as no fresh issues of this paper have been lately made by government, it is continually decreasing in circulation, while banco increases. Both currencies are made payable to bearer on demand, and are accordingly discharged when presented for payment.

RICLA, in *Geography*, a town of Spain, in Aragon, on the Xiloca, anciently called "Nertobriga;" 14 miles N.E. of Calatayud.

RICOCHE BATTERY, in *Fortification*. See BATTERY & *Ricochet*.

RICOCHE Firing, in the *Military Art*, is a method of firing with pieces elevated from three to six degrees, and loaded with a small charge, so that the ball may bound and roll along the inside of the parapet. The ball or shot, thus discharged, goes rolling and bounding, killing, maiming, or destroying all it meets with in its course, and creates much

greater disorder, by moving thus slowly, than if thrown from the piece, whose elevation is greater, with greater violence.

The word *ricoché* signifies *duck and drake*, terms applied to the bounding of a flat stone thrown almost horizontally into the water.

RICOTE, in *Geography*, a town of Spain, in the province of Murcia; 20 miles N.W. of Murcia.

RICOTIA, in *Botany*, a Linnæan name whose origin no one has been able to explain, nor can we throw any light upon it. It has the appearance of a proper name, and was probably given in honour of some obscure botanist.—Linn. Gen. 337. Schreb. 440. Willd. Sp. Pl. v. 3. 477. Mart. Mill. Dict. v. 4. Ait. Hort. Kew. v. 4. 98. Juss. 239. Lamarck Dict. v. 6. 210. Illustr. t. 561. Gærtn. t. 142.—Class and order, *Tetradynamia Siliquosa*. (*Siliculosa*; Brown.) Nat. Ord. *Siliquosa*, Linn. *Crucifera*, Juss.

Gen. Ch. Cal. Perianth inferior, deciduous, of four, oblong leaves, approximating in a parallel manner. Cor. cruciform, of four, obcordate petals, spreading. Stam. Filaments six; four the length of the tube; two somewhat shorter: anthers oblong, acute. Pist. Germen superior, cylindrical, the length of the stamens; style scarcely any; stigma acute. Peric. Pod sessile, lanceolate-oval, with one or two cells, and two flat valves. Seeds mostly four, orbiculate, compressed.

Ess. Ch. Pod of one cell, oblong, compressed: valves flat.

1. R. *egyptiaca*. Egyptian Ricotia. Linn. Sp. Pl. 912. (*Lunaria foliis supradecompositis: foliolis trifidis, siliquis oblongis pendulis*; Mill. Ic. v. 2. 113. t. 169.)—Native of Egypt, flowering in June and July.—Root annual. Stem a foot high, smooth and branching. Leaves unequally pinnate; leaflets various, some undivided, others three-lobed, of a lucid green. Flowers purple, on long stalks, at the sides and ends of the branches, in small, loose clusters. Pods drooping, when ripe of a pale brown colour.

This genus is very nearly allied to *Lunaria*, from which indeed it chiefly differs in having a sessile, not stalked, pod.

RICZIWOL, in *Geography*, a town of the duchy of Warfaw; 30 miles N. of Posen.

RIDA, a town of the Valais; 4 miles S.E. of Sion.—Also, a town of Sweden, in the province of Upland; 24 miles N.E. of Stockholm.

RIDALE, or RISEDALE, a river of England, in the county of York, which runs into the Swale, near Richmond.

RIDAL-HEAD, a mountain of England, in Cumberland; 2 miles N. of Ambleside.

RIDDERHUDE, a town of the duchy of Bremen; 8 miles N. of Bremen.

RIDDLE. See *ÆNIGMA*.

RIDDLE, in *Rural Economy*, a sort of sieve used to separate dust and the seeds of plants from corn. They are made of different forms and sizes, for different uses.

RIDE of hazle, or other wood, is a group or cluster of sprigs shooting out of the same root or stock.

RIDE, or *Riding*, in the *Manege*. To ride signifies to learn to ride. Thus, he rides under a good master. For an account of the origin and history of the art of riding, we refer to the article HORSE.

In addition to the observations which occur under that article, in proof of the antiquity of the art of riding, we shall here introduce some other considerations, which tend to evince the priority of riding to the use of chariots. Egypt appears to have been the spot in which the horse seems to have been first subdued and disciplined by man; and

and it is evident from the Mosaic history, that in the first instance where mention is made of Pharaoh's chariots, he is likewise said to have had his horseman: which word, in the Hebrew language, is explained by the commentators to mean one who sits upon and guides a horse. Besides, the Hebrew word, "parash," horseman, is derived, as Buxtorf says, from a Hebrew root, which signifies to *prick* or *spur*; and the rider, or spurrier, was so denominated, because he used to prick or spur the horse. Aben-Ezra says, that the horseman was so called from wearing spurs on his heels. By this account and explanation of the word, which in the Hebrew signifies a "horseman," we are informed of the great antiquity of spurs; and may reasonably conclude, that the art of riding was not only known, but, from the invention of spurs, had also received an improvement, not unworthy of the discovery of more discerning times; and seems to imply, that riding was not only familiar, but even advanced in those primitive times to a degree of exactness, perhaps, not hitherto suspected. The arguments here, and also under the article HORSE, alleged in proof of the seniority of horsemanship to that of the use of chariots, may be strengthened by the following passage in the book of Job, where, speaking of the ostrich, he says, "she listeth herself on high, she scorneth the horse and its rider;" which expression seems to imply that it was a custom, as it is now in some nations, to hunt this bird on horseback, and that she was superior to the swiftest horse. Hence it must be granted that riding was practised in his country, and at the time in which he lived; nor is it to be forgotten, that he lived in a country distinguished above others for its horses, and in which no chariot was ever known to have been used. We may also add to the same purpose, the noble description which he gives of the horse, so known and so admired, in which he speaks of him only as being rode, and not driven in a carriage: and if this writer, as some learned persons have thought, lived long before the time of Moses, what he says in relation to this subject must be anterior to the Mosaic history; and if that be the case, the antiquity of equitation will be carried so high, as to put it beyond the reach of inquiry and investigation. In the description just referred to, the English translators make Job say, "that this animal's neck is clothed with *thunder*;" an expression no less false than absurd. The true rendering of this passage is, that his neck is clothed with a *mane*. Thus Bochart, Le Clerc, Patrick, and other commentators translate it. Bochart says, that the word, which in Hebrew signifies *thunder*, is synonymous with that for the *mane* of the horse; but this being the case, it is astonishing that the translator should have set aside the just and natural signification, and have chosen to cover the horse's neck with *thunder*, instead of a *mane*; nor is it less amazing, that this nonsense should have been extolled by the author of the "Guardian," and others, as an instance of the sublime. We shall here observe, that the Grecians, in many instances, chose mares for riding before horses. Alian says, they thought them fitter for the course; and Virgil only names the mares of Epirus, as running in the Olympian race. Pliny says, they were swifter than horses. Berenger's Hist. and Art of Horsemanship, vol. i. p. 12, &c.

The knowledge and utility of the art of riding consist in being able to discern, and dextrous to employ, the means by which the horse may be brought to execute what the rider requires of him, with propriety, readiness, and safety: and this knowledge in the man, and obedience in the horse, should be so intimately connected, as to form one perfect whole; this union being so indispensably necessary, that, where it is not, there is no meaning between the man and

horse: they talk different languages, and all is confusion.

The Greeks, who excelled in the art of riding, were accustomed to mount and dismount, by vaulting and leaping from and upon the backs of their horses, as well as from one horse to another. These feats of activity seem to have been first practised in battle, and in those ages when saddles, and consequently stirrups, were unknown. The utility of this method must be acknowledged; for if one horse was tired, wounded, or killed, his master had another for his service; two or three being led into the field, which were used as occasion required. These exercises, so essentially necessary in war, were, after a time, performed in the public games, and other occasional exhibitions, merely to shew the nimbleness and address of the horseman; and the modern art of vaulting, in all its variety of postures and methods, and which has *now* little more in view than to display the activity of the performer, is, without doubt, derived from this ancient practice; as well as the whole modern manege, except some few experiments, calculated merely for grace and pleasure, is borrowed from the different motions and evolutions performed by men and horses in battle. To this likewise we owe the solemnities and sports of tilts, tournaments, and jousts; invented as a mock-war, to fill up the lazy hours of peace, to inspire and keep alive a martial spirit, and to render the body active, robust, and expert in the feats of arms.

It is well known that the Romans were indebted to Greece for many arts and useful improvements, and particularly horsemanship, which was received and adopted by them with such eagerness, and cultivated with such diligence and zeal, that they soon were able to excel their masters. Romulus, at a very early period, instituted his order of "equites," or horsemen, as Athens and Sparta had done before, on purpose to encourage the practice of riding, and engage his new subjects to keep horses at their own expence, which, in those times, were so costly, that the rich alone were equal to the charge of maintaining them. Among the Romans they had a horse called "singularis," or single, upon which a man rode without a saddle, using only a cloth, like the Greeks, fastened with a surcingle, or else sitting upon the bare back. The riders were also, occasionally, tied and bound to their horses by these girths, that they might sit more firmly and securely; but the practice was imprudent and dangerous, as they were thus liable to be dragged and torn by the horse, in case they were defeated, like the warrior described by Silius Italicus (lib. 4. Punic.):

"——— Rapiurque pavore

Traetus equi, vincis connexa ad cingula membris."

Lock saddles, now but little used, are liable to the same objection.

The art of riding subsists in various modes and different degrees of skill and perfection among different nations. In Arabia, where the horses are the finest and best of their kind, their owners manage them with singular dexterity. Their saddles have the back part, or "candle," so high, that it reaches more than half-way up the rider's back. The stirrups are flat, in the Turkish manner, and contain the whole foot. They never use a girth, which makes it more difficult to mount and keep their seat. The Arabian youth understand the equilibrium, and keep their body in a just counterpoise; being so dextrous, that they will stand on the saddle, while the horse runs at full speed, sling their lances, turn round, throw themselves over, and stand upon their heads; the horse continuing his career all the time.

Similar evolutions were practised by the ancient Romans. The Turks ride with their stirrups so short, that their knees are almost as much bent, as when they sit upon their hams upon a sofa. Their saddles are as large and unwieldy as a pack-saddle: they fasten and secure them upon the horse by a large girth, which passes over them, and prevents the saddles from turning, which their great weight would otherwise make them do. The bridles are generally gilt and ornamented, but otherwise very clumsy and ill-made. The Turks seldom use spurs, or carry a whip or switch; and yet they have an absolute command over their horses, and make them do whatever they please. In riding, they use only a stick, about three feet in length, and of the size of a large cane. This they hold by the middle, and strike the horse with it on his neck with either end, to direct and compel him to turn; making them run at full speed, and laying them out so rapidly, as almost to make their bellies touch the ground; the riders, at the same time, striking their darts into a turban, or tossing them in the air, riding after, and catching them before they fall to the ground. Others, especially the Arabs belonging to the sultan, will leap from one horse to another, running at their utmost speed. Others will creep under the belly, and up to the saddle again; others will turn two or three times round the horse's neck, and others will stand upright upon the saddle, and turn their faces to the tail, the horses all the time going at their utmost stretch.

The Persians have great personal address and activity on horseback. They play at "Mall" mounted on their horses, and strike the ball with certainty and surprising skill. They place also upon the top of a tree, or high pole, an apple, as a mark to shoot at with arrows. They set off at full speed, and when they are got beyond the mark, turn themselves round towards the croupe, draw their bows, and in this pace, and this attitude, seldom fail to hit the apple. The Tartars have, in all ages, been famous, under different names, for their love of horses, whose flesh they eat, drinking the milk of the mares, and skill in riding. It is a practice with them to tie the reins of their bridles to their girdles, and by the motion of their bodies alone to govern and direct their horses; pulling them into different attitudes, and making them perform a variety of evolutions. By this method they have their hands at liberty for the use of their weapons, which they manage with a skill surpassing that of other nations. Some will hold their bows in the same hand in which they hold their bridles, and at the same time draw the bow, and guide their horse with great address, always riding with their stirrups very short, in order to collect themselves better, and be able to rise up, as it were, when they are going to attack an enemy, and strike a blow.

The venerable Bede says, that the English began to use saddle-horses about the year 631, when prelates and others rode on horseback, who till that time were accustomed to go on foot; but that if, upon urgent occasions, they were obliged to ride, they used mares only, in token of their humility; the mare not being so full of pride or spirit as the horse. In the reign of Edward III. the horses called "Dextrarii," corresponding to those that are now termed *managed* horses, or horses *dressed* and disciplined for war, were held in the highest estimation, and appropriated to military exercises; and upon common occasions, persons of rank and consideration always rode upon horses of inferior degree, distinguished by the names of "Courfers, Amblers, Palfreys, Hackneys, Nags, and Foneys," recommended by their easy paces and quiet temper. In several countries it was a custom, rigorously observed, that no knight of chivalry, or other gentleman, should ride upon a mare, it being

thought dishonourable and vile. The mares were always devoted to the cart, and all the ignoble services. The Spaniards, Turks, and some other nations, still adhere to this absurd notion, upon all occasions. The Dextrarii above-mentioned were called "magni equi," or great horses, being of the largest size, and intended to serve in war or for the exercise of the tournament; and as these great horses were required to be *dressed* or taught, that they might perform their tasks with readiness and fidelity; and as it is necessary that the rider should have knowledge and skill to guide his horse, those persons who professed the science of arms were obliged to learn the art of managing their horses, in conformity to certain rules and principles; and hence came the expression of learning to "ride the great horse."

After an ample review of the state of horses in England, Berenger takes occasion to distribute them into two general classes, which may be arranged under two distinct periods of time. In the first era, as it was an universal custom for horsemen to fight in armour, the burden was so heavy, and the service so severe, that none but *large* and *stout* horses were equal to the task. The practice of raising such a breed of horses began about the time of Henry II., or somewhat earlier, and continued till towards the end of the reign of Elizabeth. About the reign of James, armour, being rendered useless by the invention of fire-arms, was laid aside; and the *great* horse became useless, and, on many occasions, even improper. *Lighter* and more *nimble* horses were therefore brought into use, and here begins the era which comprehends the second class of horses, called the *light* or *swift* breed. This ingenious writer closes his review with observing, that, however highly gifted the horses may be, there are *duties* incumbent also upon those who are to ride them, without an attention to which all the talents of the horse, instead of being called forth and improved, will be crushed, extinguished, and nature have been kind in vain. These duties are comprehended under the "art of riding." This art has been, as this author regrets, so long neglected and despised, that one would be almost prompted to conclude that a fatality had constantly attended it in this country; favoured as it is with every advantage for breeding, nourishing, and procuring the finest horses of all sorts, and with a nobility and gentry, whose love of exercise, activity, courage, personal endowments, and commanding fortunes, would qualify them to take the lead, and "witch the world with noble horsemanship;" yet, with all these high privileges, they have suffered it to languish, and almost perish in their hands; for a length of time it has been able to boast but of a very few persons who have stood forth as its avowed friends and protectors. The duke of Newcastle honoured it with his practice, and greatly enriched it with his knowledge. Sir Sidney Medows, sir William Hope, and the earl of Pembroke, are also mentioned with approbation and respect. Our author adds, that since the accession of his present majesty, the prospect has brightened, and better times begin to dawn. Since this happy event, the art has manifested signs of recovery; public riding houses have been opened, encouraged, and frequented; and the art has been so far protected and honoured by his majesty, that, as our author says, we may expect to see the golden age of horsemanship revive, and that men will no longer "complain of the want of excellent horses, nor the horses *groan* for want of worthy riders." This art has been much indebted to the publication of "The History and Art of Horsemanship," by Richard Berenger, esq., which has furnished various extracts, to be found under their appropriate titles, in our Cyclopædia. We shall here subjoin some particulars that

that have not elsewhere been introduced, and close the article with suitable references for the direction of the reader.

The posture of the body is an object of primary consideration in the art of riding. In reference to this object, the body may be divided into three parts, two of which are moveable, and the other immovable. Of the two moveable parts, the first is the trunk or body, down to the waist; the second is from the knees to the feet; and the remaining immovable part is that between the waist and the knees. The parts which ought to be without motion are the fork or twist of the horseman, and his thighs; and for this purpose, they ought to have a certain hold or centre upon which to rest, so that no motion of the horse may disturb or loosen them; this point or centre is the basis of the hold which the horseman has upon his horse, and is called the "seat;" and hence it must appear, that not only the grace, but the symmetry and true proportion of the whole attitude depends upon those parts of the body that are immovable. Let the horseman then place himself at once upon his twist, sitting exactly in the middle of the saddle; let him support this posture in which the twist alone seems to sustain the weight of the whole body, by moderately leaning upon his buttock; let his thighs be turned inward, and rest flat upon the sides of the saddle; and in order to this, let the turn of the thighs proceed directly from the hips, and let him employ no force or strength to keep himself on the saddle, but trust to the weight of his body and thighs: this is the exact equilibrium: in this consists the firmness of the whole building, a firmness which young beginners are never sensible of at first, but which is to be acquired, and will always be attained, by exercise and practice. A moderate stress upon the buttocks is necessary, because a person that sits full upon them can never turn his thighs flat upon the saddle; and the thighs should always lie flat, because the fleshy part of the thigh, being insensible, the horseman would not otherwise be able to feel the motions of his horse; the turn of the thigh should be from the hip, because this turn can never be natural; but as it proceeds from the hollow of the hip-bone, the horseman never avails himself of the strength or help of his thighs, because, besides their being then less steady, the closer he pressed them to the saddle, the more would he be lifted above the saddle; and with respect to his buttock and thighs, he ought always to be in the middle of the saddle, and sit down full and close upon it. With regard to the position of the body or trunk, which is the first of the moveable parts, and which comprehends the head, the shoulders, the breast, the arms, the hands, the reins, and the waist of the horseman, we shall begin with the head. This should be free, firm, and easy, and thus prepared for all the natural motions which the horseman may make in turning it to one side or the other. The shoulders only influence, by their motions, that of the breast, the reins, and the waist. The horseman should present or advance his breast, by which his whole figure is opened and displayed; he should have a small hollow in his reins, and push his waist forwards to the pommel of the saddle, because this position corresponds, and unites him to all the motions of the horse. The mere throwing of the shoulders back produces all these effects in the degree that is requisite; whereas if we were to look for the particular position of each part separately, and by itself, without examining the connection subsisting between the motions of one part with those of another, there would be such a bending in the reins, that the horseman would be hollow-backed; and by forcing his breast forward and his waist towards the pommel of the saddle, he would be slung back, and must sit upon the rump of the horse. The

arms should be bent at the elbows, and the elbows should rest equally upon the hips. It is indeed the bridle-hand which ought to be steady and immovable, and hence it might be concluded, that the left elbow only ought to rest upon the hip; but grace consists in the exact proportion and symmetry of all the parts of the body; and having the arm on one side raised and advanced, and the other kept down and close to the body, would present an awkward and disagreeable appearance. It is this which determines the situation of the hand which holds the whip, the left hand being of an equal height with the elbow; so that the knuckle of the little finger and the tip of the elbow be both in a line; this hand then being rounded neither too much nor too little, but so that the wrist may direct all its motions, the right hand, or the whip-hand, should be placed lower and more forward than the bridle hand. It should be lower than the other hand, because if it were on a level with it, it would restrain or obstruct its motions, and if it were higher, it could not take so great a compass as the bridle-hand, which must be always kept over-against the horseman's body; it is absolutely necessary to keep the proportion of the elbows, that it should be lower than the other. The second division of the moveable parts includes the legs and feet. The legs serve for two purposes; they may be used as aids or corrections to the animal; they should therefore be kept near the sides of the horse, and in a line with the rider's body; for being near that part of the horse's body where his feeling is most delicate, they are ready to perform their office at the moment when they are wanted. Besides, as they are an appendage to the thighs, if the thigh is upon its flat in the saddle, they will necessarily be turned just as they ought, and will infallibly give the same turn to the feet, because the feet depend upon them, as they depend upon the thighs. The toe should be held a little higher than the heel, for the lower the toe is, the nearer will the heel be to the sides of the horse, and must be in danger of touching his flank. Many persons, however, when they raise their toe, bend and twist their ankle, as if they were lame in that part. The reason is plain; it is because they make use of the muscles in their legs and thighs, whereas they should employ only the joint of the foot for this purpose; a joint given by nature to facilitate all the motions of the foot, and to enable it to turn to the right or left, upwards or downwards. Such, according to Mr. Berenger, is the mechanical disposition of all the parts of the horseman's body.

The hand, in horsemanship, admits of five different positions, in order to guide and govern the motions of a horse. The first is that general position from which proceed, and indeed ought to proceed, the other four.

Hold your hand three fingers breadth from your body, as high as your elbow, in such a manner that the joint of your little finger be upon a right line with the tip of the elbow; let your wrist be sufficiently rounded, so that your knuckles may be kept directly above the neck of your horse; let your nails be exactly opposite your body, the little finger nearer to it than the others, your thumb quite flat upon the reins, which you must separate by putting your little finger between them, the right rein lying upon it: this is the first and general position.

Does your horse go forwards, or, rather, would you have him go forwards? Yield to him your hand, and, for that purpose turn your nails downwards, in such a manner as to bring your thumb near your body; remove your little finger from it, and bring it into the place where your knuckles were in the first position, keeping your nails directly above your horse's neck: this is the second.

Would you make your horse go backwards? quit the first position; let your wrist be quite round; let your thumb be in the place of the little finger in the second position, and the little finger in that of the thumb; turn your nails quite upwards, and towards your face, and your knuckles will be towards your horse's neck. This is the third.

Would you turn your horse to the right? leave the first position, carry your nails to the right, turning your hand upside down, in such a manner, that your thumb be carried out to the left, and the little fingers brought in to the right. This is the fourth position.

Lastly, would you turn to the left? quit again the first position; carry the back of your hand a little to the left, so that the knuckles come under a little, that your thumb may incline to the right, and the little finger to the left. This makes the fifth position.

These different positions, however, alone are not sufficient; we must be able to pass from one to another with readiness and order.

Three qualities are essentially necessary to the hand. It ought to be firm, gentle, and light. We call that a firm or steady hand, whose feeling corresponds exactly with the feeling in the horse's mouth, and which consists in a certain degree of steadiness, constituting that just correspondence between the hand and the horse's mouth, which every horseman wishes to find.

An easy or gentle hand is that which, by relaxing a little of its strength and firmness, eases and mitigates the degree of feeling between the hand and horse's mouth, which we have already described.

Lastly, a light hand is that which lessens still more the feeling between the rider's hand and the horse's mouth, which was before moderated by the gentle hand.

The hand, therefore, with respect to these properties, must operate in part, and within certain degrees, and depends upon being more or less felt or yielded to the horse, or withheld.

It should be a rule with every horseman not to pass, at once, from one extreme to another, from a firm hand to a slack one; so that in the motions of the hand you must, upon no account, jump over that degree of sensation which constitutes the easy or gentle hand. Were you at once to go from a firm hand to a slack one, you would then entirely abandon your horse, you would surprise him, deprive him of the support he trusted to, and precipitate him on his shoulders, supposing you do this at an improper time. On the contrary, were you to pass from the slack to the tight rein, all at once, you must jerk your hand, and give a violent shock to the horse's mouth; which rough and irregular motions would be sufficient to falsify the firmest appui, and ruin a good mouth.

It is indispensably necessary, therefore, that all its operations should be gentle and light; and, in order to this, it is necessary that the wrist alone should direct and govern all its motions, by turning and steering it, if we may so say, through every motion that it is to make.

In consequence, then, of these principles, we insist that the wrist be kept so round that your knuckles may be always directly above the horse's neck, and that your thumb be always kept flat upon the reins. In reality, were your wrist to be more or less rounded than in the degree we have fixed, you could never work with your hand but by the means of your arm; and, besides, it would appear as if it were lame; again, were your thumb not to be upon the flat of the reins, they would continually slip through the hand, and by being lengthened, would spoil the appui; and, in order to recover them, you would be obliged every moment

to raise your hand and arm, which would throw you into disorder, and make you lose that justness and order without which no horse will be obedient, and work with readiness and pleasure.

Those motions, which are called descents of the hand, are made three different ways, either by dropping the knuckles directly, and at once, upon the horse's neck, or by taking the reins in the right hand, about four fingers' breadth above the left, and letting them slide through the left, dropping your right hand at the same time upon the horse's neck, or else by putting the horse under the button, as it is called; that is, by taking the end of the reins in your right hand, quitting them entirely with your left hand, and letting the end of them fall upon your horse's neck. These motions, however, which give a prodigious grace to the horseman, never should be made but with great caution, and exactly at the time when the horse is quite *together*, and in the hand; and you must take care in counterbalancing, by throwing back your body, the weight of the horse upon his haunches.

The appui being always in the same degree, would heat the mouth, would dull the sense of feeling, would deaden the horse's bars, and render them insensible and callous; this shews the necessity of continually yielding and drawing back the hand, to keep the horse's mouth fresh and awake. See APPUI.

The effects produced by the several positions and motions of the hand above described, are as follow: the hand directs the reins, the reins operate upon the branches of the bit; the branches upon the mouth-piece, and the curb; the mouth-pieces operate upon the bars, and the curb upon the chin of the horse.

The right rein guides the horse to the left, the left rein to the right. Would you go to the right? you pass to the fourth position of the hand, that is, you carry and turn your nails to the right; now, in carrying thus your nails to the right, and reversing your hand in such a manner that your thumb points to the left, and your little finger being raised turns to the right; you, by this means, shorten your left rein; it is this left, therefore, that turns and guides the horse to the right. Would you go to the left? pass to the fifth position; you will carry the back of your hand to the left, so that your nails will be turned downward a little, your thumb will be to the right, the little finger to the left; this will shorten the right rein; the right rein, therefore, determines your horse to the left.

We have already said, that the effect which the mouth-piece has upon the bars, and of the curb upon the chin, depends upon the branches of the bit; when the branches rise, or are turned upwards, the mouth-piece sinks; and when the branches sink, the mouth-piece rises; so that when your horse is going straight forward, if you keep your hand low, and close to your body, the mouth-piece then presses stronger upon the bars; and the chain or curb having, in consequence, more liberty, acts less upon the beard. On the contrary, if you keep your hand high, a little forward, and consequently a little out of the line of the end of the branches, the mouth-piece then sinks, and the branches, of necessity, operate upon the curb, which presses then very strongly upon the beard. Now, in order to place, and bring in your horse's head, you must hold your hand low; and, in order to raise and lighten a horse that weighs upon the hand, and carries his head too low, you must advance your hand a little, and keep it high.

Would you have your horse go back, come to the third position? but take care to round your wrist exactly, in order to work equally with both your reins; and by this means aid your horse more effectually to go back straight and balanced

lanced between your legs, which he could never do, if one rein were to operate stronger than the other.

There are particular cases where the reins are separated, and one held in each hand; it is usual to separate them, when you trot a young horse, or when you are to work one who is disobedient and resists his rider; upon these occasions, keep both your hands upon a level, low, and near your body. To turn to the right, use your right rein; to go to the left, use your left rein; but in order to make them have their effect, move your arm gently, turning it a little from your body, keeping your hand always low, and even near your boot.

Every horseman, who would be perfect in his art, ought to know the disposition of his horse, the vices to which he is subject, the causes from which they proceed, and the proper method of restraining or amending them. Sometimes a horse will rebel, when you press him to do something of which he is ignorant; in this case he should be taught what you expect. If he knows, but cannot, through inability, perform what you require, endeavour to assist nature by the help of art; but if he knows, and is able to do what you expect, first try every method which patience and perseverance can suggest, and if you fail, compel him by force and severity. A horse may be imperfect and bad from four causes: weakness, heaviness in his make, want of courage, and sloth; and four qualities must conspire to make a good horse, *viz.* strength, activity, courage, and judgment. By a combination or mixture of these different qualities, are the various dispositions of horses produced; and the remedy ought to be adapted to the nature of the animals as well as to the disorder which the horseman proposes to rectify. A horse may be difficult to be mounted; examine the source of this vice. It may be owing either to the ignorance, or the brutality, of those who have first had to do with him, or perhaps that the saddle may have hurt him, or else to a temper naturally bad. To whatever cause it may be owing, remember never to beat him; for instead of curing him, you would certainly confirm him in his vice; clap him gently when you approach him, stroke his head and mane, talk to him, and as you talk, clap the seat of the saddle; keep yourself still all the while, put your foot only in the stirrup to encourage your horse, without doing any more, in order to make him familiar, and to lose all apprehension and fear when he is going to be mounted; by little, and by degrees, at last, he will let you mount him; you will immediately get down, and remount, and so successively for several times together, without attempting to do any thing else; but send him back to the stable. If it happens that when you are upon him, he runs from the place where you got upon him, bring him to it immediately, keep him there some time, coax him, and send him away. The first lessons ought to be well weighed, when you undertake to bring a young horse to obedience, and to reclaim him from liberty to the subjection of the bridle, saddle, and the weight of his rider; so restrained, it is not surprising if he should employ all his strength against you in his own defence.

The generality of colts are difficult to be turned and guided as you would have them go; we ought not, however, to be surprised at this their first disobedience. It must be imputed to the habit they acquire from their birth, of constantly following their dams; indulged in this liberty, and subjected all at once by the bit, it is but natural they should rebel. There is no way of eradicating these first impressions, but by gentleness and patience. A horseman who should make use of force and correction, and employ it all at once upon a young horse, would discourage and make

him be vicious ever after. If, therefore, your horse refuses to go forward, you must lead another horse before him; the person who rides the colt will try from time to time, and, insensibly, to make the colt go abreast with him, and afterwards get before him. If, being surprised at seeing the horse no longer, he stops, or runs back, the rider must endeavour to drive him forward either by his voice, or some kind of slight instrument, or he that rides the other horse may give him a stroke with the chambriere, in order to make him go forward; if these methods should not succeed, he will go before him again with the other horse; by degrees (for one lesson will not be sufficient) the colt will grow accustomed to it, and, at last, will go on of himself.

Molt horses who start have some defect in their sight, which makes them fear to approach the object. The horseman, upon these occasions, instead of having recourse to punishment, which often serves only to alarm the horse, and extinguish his courage and vigour, should first endeavour to lead him gently towards the object that terrifies him, either by encouraging him with his voice, or by closing his legs upon him, to make him go up to the object that terrifies him. If he will not go towards it, you may give him the spurs, but with discretion; and by coaxing and caresses, push him towards it insensibly. Severe correction will never cure him of this fearful temper, which is a fault inherent in his nature; nor of any imperfection in his sight, which is a disorder belonging to him; but the habit of view and smell-ing may, in time, remedy the defects of nature.

If, notwithstanding, you perceive that sloth and malice are added to these faults, you must use, as you find it necessary, both mildness and severe correction; and you will bestow them in proportion to the effect they produce. For the rest, be careful never to surprize and alarm a young horse which is shy, and apt to start; never terrify him with what he most fears; never beat him in order to make him come up to an object of which he is afraid; accustom him by degrees to it, and have patience; the fear of punishment does oftentimes more harm, and is more dreaded by him, than the very object which first alarmed him.

There are some horses who are struck with such terror at the sight of a stone, or wooden-bridge, at the sound and echo of the hollow part of it, that they will fling themselves headlong into the water, without the rider's being able to restrain him. They are to be cured of this apprehension, by covering the pavement of their stall with wooden planks, between two and three feet high. The horse standing constantly upon them, his feet will make the same noise as they do when he goes over a bridge; and he will, of course, grow familiar to the sound, and lose all apprehension of it.

To accustom them likewise to the noise of the water running under the bridge, lead him to a mill, fix two pillars directly over-against the wheels, and tie your horse constantly for two hours together, several times in the day. Having done this, bring him back to the bridge, and let an old horse, that is not afraid, go before him upon the bridge, by degrees you will find him go over a bridge as readily and quietly as if he had never had the least apprehension.

For horses that are addicted to lie down in the water, you must provide yourself with two little leaden balls, and tie them to a piece of packthread, and, in the moment that he is lying down, you must drop these into his ears; and if he rises instantly, or forbears to lie down, draw them back; but this method is not less sure than that of breaking a flask filled with water upon his head, and letting the water run into his ears.

Fire, smoke, the smell of gunpowder, the noise of guns, or other arms, naturally surprize and frighten a horse. There

There are few that will come near fire, or pass by it, without difficulty. There are many occasions, however, in which it is necessary; it is therefore proper to accustom your horse to it. In the first place, begin with your horse by letting him see it, and for that purpose tie him between two pillars, and hold before him, at about thirty paces distant, a burning whisp of straw; this should be continued for some days together, repeating it several times each day. Let the person who holds the brand advance towards the horse step by step; and let him take care to advance, or stop, often, as he perceives the horse is moved, or less frightened, who, in a short time, will be emboldened, and no longer afraid of the fire. After this, get upon him, carry him slowly, and as it were insensibly, towards the brand, the person who holds it taking care not to stir; if your horse comes up to it without being frightened, let the man on foot walk on, and let the horse follow the fire. Would you bring your horse to go across a fire, lay upon the ground some straw about half burnt out, and he will pass over it.

With respect to the noise of arms and drums, let your horse hear them before you give him his oats; do this regularly every day, for some time, and he will be so used to them as not to mind them.

A horse is said to be *entier*, in its natural sense whole, entire; and, in the figurative meaning, obstinate, stubborn, opinionated, to that hand to which he refuses to turn. A hurt in his foot, leg, or shoulder, may often be the cause of his refusing to turn to that side where he feels any pain. A hurt in his reins, or haunches, a curb or spaving, which, by hindering him to bend, and rest upon his hocks, may make him guilty of this disobedience. Art can do little towards curing these evils; consequently, a horse so affected will never dress well, because he never can be made supple and ready; besides, every horse is naturally inclined to go to one hand more than the other, and then he will go to that hand on which he finds himself the weakest, because with the strongest he can turn more easily.

It is a known fact that horses are naturally inclined to go better to one hand than to the other. The halter, the bridle, the saddle, and the girths, are all put on, and tied on the left side; when they are rubbed or curried, the man stands on their left side; the same when they are fed; and when they are led out, the man holds them in his right hand, consequently their head is pulled to the left; here is a chain of reasons sufficient to induce us to believe, that if they are readier to turn to one hand than the other, it is owing to a habit and custom which we ourselves have given them.

We seldom meet with horses that are readier to turn to the right hand than the left; and when it so happens, it oftentimes denotes an ill temper; it demands much time and pains to cure them of this fault.

*Note.*—It is not proper to use severe correction to make a horse obey who refuses to turn to one hand; if he is cold and dull, he will lose all his vigour and courage; if he is of an angry temper, hot, and brisk, you would make him desperate and mad; work him then upon the principles of art, and pursue the method you think most likely to reform his ill habits, and reduce him to obedience. If he obstinately refuses to turn to one hand, begin the next lesson by letting him go to his favourite hand a turn or two; finish him on the same hand, and by degrees you will gain him; whereas, were you to do otherwise, you might make him be ever after rebellious. A horse that strenuously resists his rider, if he has vigour and courage after he is reduced and conquered, will, nevertheless, succeed in what you want of him, provided he is under the direction of an able and knowing person, who understands the aids of the hands

and legs, and their mutual harmony and correspondence. Such a horse is even preferable to one who never rebels, because, in this last, nature may be deficient, if we may be allowed the expression, with respect to his want of strength and resolution.

In order to teach your horse to turn to both hands, you must separate your reins, as we have already mentioned; do not confine him too much, support him moderately, so that you may easily draw his head to one side or the other, as you would have him go, and to give him the greater liberty to turn.

If he refuses to obey, examine him; if he is by nature impatient, hot, and vicious, by no means beat him, provided he will go forward; because being held in hand, and kept back a little, is punishment enough; if he stops, and tries to resist, by running back, drive him forward with the chambriere.

The resistance of a horse whose mouth is faulty, discovers itself more in going forward than backward, and in forcing the hand. A horse of this sort ought never to be beat, he ought to be kept back, as we have just now said; you must endeavour to give him a good and just appui, and put him upon his haunches, in order to cure him of the trick of leaning upon his bit, and forcing the hand. If your horse is heavy, never press or put him together, till you have lightened his fore-part, and put him upon his haunches, for fear of throwing him so much upon his shoulders, that it may be very difficult afterwards to raise him. Take particular care to lighten every horse that is heavy before, and has malice in his temper at the same time; for if you were to press him, he would resist you through vice; in which case, by his want of strength on one hand, and being heavy and unwieldy on the other, you would be exposed to evident danger.

A restive horse is one that refuses to go forward, who standing still in the same place, defends himself and resists his rider in several different manners; it is much to be feared that one should lose all temper with such a horse, since it requires a great deal of patience to cure so capital a fault, and which, perhaps, by habit and time, is so rooted in him as to be almost natural to him. Treat a horse of this sort, who has been too much constrained and tyrannized over, with the same lenity that you would shew to a young colt. The spurs are as improper to be used to one as the other; make use of your switch, in order to drive him forward, as you will alarm him less, for the spurs surprize a horse, abate his courage, and are more likely to make him restive, than oblige him to go forward, if he refuses to do so.

There is likewise another method to punish a restive horse, it is to make him go backward the moment he begins to resist; these corrections often succeed; but the general rule is to push and carry your horse forward, whenever he refuses to advance, and continues in the same place, and defends himself either by turning or flinging his croupe on one side or the other; and, for this purpose, nothing is so efficacious as to push him forward vigorously.

The most dangerous of all defences a horse can make, is to rise directly upon his hinder legs, and stand almost quite straight, because he runs a risk of falling backward, and in that case the rider would be in danger of his life. People have endeavoured to correct this vice by a method of punishment, which might prove dangerous unless given in time, and with the greatest exactness.

Whenever the horse rises straight up, throw your body forward, and give him all the bridle; the weight of your body upon his fore-parts will oblige him to come down; in the minute that his fore-feet are coming to the ground, give

give him both the spurs firm, and as quick as you can. These aids and corrections, however, must be given with the greatest caution and exactness; for were you to give him the spurs when he is in the air, he would fall over, whereas if you watch the time so as not to spur him but when he is coming down, and his fore-feet near the ground, it is then impossible he should fall backward, for then his balance is destroyed, and he is upon all his legs again, and cannot rise without first touching the ground, and taking his spring from thence; if, therefore, you give him the spurs before he is in a situation to rise again, you will punish him, and drive him forward at the same time.

This defence is still more dangerous in horses who are of a fiery temper, and weak in their haunches at the same time. These are continually apt to rise; and whatever precautions the rider may take, he is in continual danger of their coming over; the way to correct them is this; tie your horse between the pillars very short, put on a good cavesson of cord, and do not suffer him to be mounted. Prick him upon the buttock with a spur, or sharp piece of iron, in order to make him strike out behind; encourage him when he kicks, and continue to make him kick, encouraging him from time to time, when he obeys; do this for a quarter of an hour every day. When you perceive that he begins to kick the moment after you so prick him, without waiting till he feels it, get upon him, hold your reins long, prick him, and let a man stand by and prick him at the same time; encourage him when he kicks, and continue to prick him, to make him do it, till he will kick readily only at the offer you make of pricking him; he ought to be brought to this point in five or six days. After this, take him out of the pillars, mount him, and trot him in the longe, and make him kick by pricking him behind; after that, let him walk two or three steps, then make him kick again, and so work him by degrees. Put him to the gallop, and if he offers to rise, prick him behind, and make him kick; nothing excels this method, to break a horse of this terrible and dangerous vice.

Those horses who are subject to kick, either when they go forward, or stand still, must be kept much together, or held in closely, to make them go backward, and you will cure them of this vice.

He who would succeed in correcting the vices of horses should never depart from this maxim; always to observe a just medium between too indulgent lenity and extreme severity; work your horse according to his strength and capacity; give your lessons in proportion to his memory; and dispense your punishments and rewards suitably to his courage and disposition. See Berenger's *Hilt. and Art of Horsemanship*, vol. ii. ch. 1, 2, 3. See also AID, AIRS, APPUI, BALLOTADES, CAPRIOLES, CORRECTIONS, CROUPADES, CURVETS, ENTIER, EPAULE *en Dedans*, GALLOP, HAND, MEZAIR, PASSADE, PASSAGE, PESADE, PILLARS, PIROUETTE, RAMINGUE, RESTIVE, STEP and Leap, STOP, TERRE-A-TERRE, TROT, UNION, VOLTE.

RIDE, among sheep farmers, a term applied to rams, which, when they are put to the ewes, are said to be at ride. See RAM.

RIDE, in the *Sea Language*, a term variously applied. Thus, a ship is said to ride, when her anchors hold her fast, so that she drives not away by the force of the wind or tide.

A ship is said to *ride well or easy*, when she does not labour heavily, or feel a great strain, when anchored in an open road or bay. On the contrary, when she pitches violently into the sea, so as to strain her cables, masts, or hull,

she is said to *ride hard*, and the vessel is termed a bad roader.

A ship *rides across*, when she rides with her main-yards and fore-yards hoisted up to the hounds, and both yards and arms topped alike.

She is said to *ride a-peck*, when one end of the yard is pecked up, and the other hangs down: this is also said of a ship, when, in weighing, she is brought directly over her anchor.

She is said to *ride athwart*, when her position lies across the direction of the wind and tide, when the former is so strong as to prevent her from falling into the current of the latter: and to *ride betwixt wind and tide*, when the wind hath equal force over her one way, and the tide another, so that she is in a manner balanced between them, and rides without the least strain on her cables. If the wind have more power over her than the tide, she is said to *ride wind-rod*.

She is said to *ride hazardous*, when, in stress of weather, she falls so deep, that the water runs in at her hauses.

She is said to *ride portoise*, when her yards are struck down upon the deck, or when they are down a-port-lall.

To RIDE land-locked, at sea. See LAND-LOCKED.

To RIDE by the Stoppers. See STOPPERS.

RIDEAU, in *Fortification*, a small elevation of earth, extending itself lengthways on a plain; serving to cover a camp, or give an advantage to a post.

The word, in its original French, signifies a curtain or cover, formed from the Latin *ridellum*. Borel derives it from *ridere*.

A rideau is also convenient for those who would besiege a place at a near distance, and to secure the workmen in their approaches to the foot of a fortress.

RIDEAU is sometimes also used for a trench, the earth of which is thrown up on its side, to serve as a parapet for covering the men.

RIDEAU, in *Geography*, a river in the eastern district of Canada, which runs into the Utwas, or Ottawa. N. lat. 45° 15'. W. long. 76°.

RIDER, a town of Arabia, in the province of Hadramaut.

RIDER, in *Artillery Carriages*, a piece of wood, somewhat higher than it is broad, and of a length equal to that of the body of the axle-tree, upon which the side-pieces rest in a four-wheel carriage; such as the ammunition-waggon, block-carriage, and sling-waggons.

RIDER is also used for after-clauses, added to bills, whilst they are depending in parliament.

RIDER-Roll. See ROLL.

RIDERS, Out. See OUT-RIDERS.

RIDERS, in *Ship Building*, interior ribs, to strengthen and bind the parts of a ship together, being fayed upon the inside stuff, and bolted through all. They are mostly used in ships of war, and are variously situated, as the *floor-riders*, which are fayed athwart the keelson, and should be placed over the first futtocks. The next are the *first futtock-riders*, which lay alongside the floor-riders, and give scarp above them: these are connected by cross-chocks athwart their heels, that scarp to each side with hook and butt. The next are *second futtock-riders*, which lay alongside of the first futtock-riders, down to the floor-riders, and run up under the orlop beams. The *third futtock-riders* lay alongside the second futtock-riders, scarp or meet the heads of the first futtock-riders, and run up to the gun-deck beams. The whole are bolted together fore and aft. Breadth and top-riders, which were above the former, seem now to be discon-

tinued

tinued in the navy, as they could only be useful in wake of the main and fore-chains, as the midships is much better strengthened now by uniting the sides and *skid-beams* together by the knees.

These riders stood diagonally, so as to fall through two or more timbers, the strength depending much thereon. The top-riders came up to the top of the side, and the breadth-riders between them and the third futtock-riders, or on the broadest part of the ship, and hence their name. Riders are not so much required in merchant-ships as in ships of war, excepting floor and lower riders in large ships (which are generally of iron, so as not to interrupt the stowage), because the cargo being stowed low down, and the rigging lighter, the upper works are not so liable to strain and labour, like those ships of war having their heavy ordnance above the line of floatation.

**RIDGE**, in *Buildings*, the highest part of the roof or covering of a house.

Ridge is particularly used for a piece of wood, in which the rafters meet.

**RIDGE-Tyle.** See **TYLE**.

**RIDGE**, in *Sea Language*, is a long assemblage of rocks, lying near the surface of the sea, so as to intercept the passage of a ship under sail.

**RIDGE-Tackle.** See **TACKLE**.

**RIDGE-Ropes.** See **ROPES**.

**RIDGEFIELD**, in *Geography*, a post-town of America, in Fairfield county, Connecticut; 10 miles S.W. of Danbury. This township was called by the Indians "Caudotowa," or high land. It was settled in 1709, and contains 2103 inhabitants.

**RIDGES**, in *Agriculture*, are pieces of ground laid up between two furrows, having always considerable length, but different small breadths, according to circumstances.

It is stated by the author of the Present State of Agriculture in Great Britain, that in many of the more fertile and populous districts, the ridges are found remarkably crooked, unequal in breadth, and made to rise towards the middle, or crown, to the height of several feet above the furrows, on either side. And he supposes that these are formed in the worst manner, to answer the purposes which are now intended by dividing a field into ridges. But this, he thinks, could not have escaped the notice of all the farmers of former periods; but that, on the contrary, from the practice being so general, it is more than probable that such form, though now considered absurd, was formerly supposed an improvement, as in the case of many other practices of antiquity; as in many of the hilly situations in Scotland, where the soils are dry, and in a tolerably level state, and where cultivation had without doubt taken place at a very early period, although at present abandoned to the growth of heath, the ridges are found as straight as those in the best cultivated districts in the kingdom. The reason which induced the cultivators of these times to construct the ridges in such forms, may, he thinks, be explained in this way; that as the lands were mostly cultivated in the open field, or run-ridge state, the furrows of the ridges were, for the most part, the mark or boundary between one farmer and another. The portion of land belonging to a tenant in any one place being on this account so small, as to prevent him from employing any other mode of drainage, than that of raising the ridge to such a height, as to permit the water to discharge itself by the furrows, without injuring the crop. It is stated, that all the ridges that are broader at one end than the other, will generally be discovered to be the narrowest at that end which is still the most wet and spouty. It is of

course conceived, that this form was purposely given them, as the only means by which lands in such a state could be drained. And that, as the most crooked ridges are found on the steep and sloping grounds, it may be supposed that that form and position were adopted by the first cultivators, as the best for preventing the soil from being washed away by sudden falls of rain, which must no doubt have been the case to a greater extent, had the ridges been straight. Each furrow, by becoming a sort of small rivulet, without any thing to impede its course, must have done more mischief to the soil than if it had been gradually taken off the circuitous course of the crooked ridges.

But from the change in the nature of possessing lands, proprietors and tenants having now, except in a few open field districts, the means of draining and forming the ridges in the most effectual manner, these old forms of ridges, which can only be useful in such cases as the above, are not only rendered useless, but operate strongly against the full improvement of the soil. But notwithstanding this, there is, it is conceived, no sort of business in which the farmer can be engaged, that demands more judgment and caution than that of levelling and altering the direction of such sorts of ridges. However, before the mode of managing this in the cheapest and most effectual manner is explained, it may be proper to shew the most suitable forms and directions in different sorts of soil, and under different circumstances of the grounds.

In forming ridges, great attention is necessary to the nature and quality of the soil, and the particular situation of it, as the size, height, and direction must, in a great measure, be governed by them. It has been observed by a late practical writer, that where the land is of such a nature as to be highly retentive of moisture, or, from the peculiarity of its position, liable to become too wet for the growth of useful crops, the ridges should in general be made narrower, and have a more rounded or convex form, than in the contrary case, or where it is exposed to injury from becoming too dry. But, in the first case, they ought not, however, to be raised so very high as is sometimes the practice, as by such means much inconvenience is often sustained from the crowns becoming too dry, and the grain ripening in a slow and partial manner. Besides, narrow ridges, with but a little elevation, are, in general, much more effectual in taking away the water that may be injurious.

It has been remarked by the writer of the Perthshire Agricultural Report, in respect to the height of ridges in lands of more dry description, that as the furrows, in general, produce less crop than any other part of the ground, the fewer furrows the better, provided the land can bear it. If the field be dry, there is not only more produce by fewer furrows, but the ridges are cloven by every ploughing (a thing that cannot be done in raised ridges with deep furrows), which keeps them in an uniform level surface, and greatly facilitates the labour of spring and harvest. Persons who are not accustomed to investigate the cause of what they daily see, are deterred from making their ridges nearly flat by the waters that stagnate, in the strips of grass and sprits that lie between the ridges, which they have raised greatly in the middle: never considering that they are working against nature, because the more the ridges are rounded the deeper are the furrows, till they become like ditches, and the more readily do clods fall down, so that they are with their own hands producing the very evil which they wish to prevent. Whereas, were the strips of flags and other trumpery torn up, were the furrows less deep, and

kept perfectly clean and open, to allow a free passage to the water, the whole would flow to the open drain at the extremity of the field; and the higher the furrows are, in respect to this drain, their relative height would make the water flow the faster. Care should always be taken that the clods that fall back into the furrows, and dam the water in such land, should be removed with the spade. The slovenliness of men in this particular circumstance, more frequently produces the stagnation complained of, and all its baneful consequences, than either ridges moderately raised, or any other cause. This he considers as perfectly satisfactory, in respect to laying out such lands into ridges in the first instance. But that, in cases in which neither the circumstances of the soil, nor the nature of its situation, require that the ridges should be formed in a particular manner, or of any certain breadth, that of making them about eighteen feet may be the most suitable, as they are found to answer well in the way of keeping the ground properly dry, and of the most convenient dimensions for turning the teams at the ends in ploughing. And that besides, the seed, where this method is pursued, can easily be sown by one cast up and another down; an operation which, in other circumstances, would be attended with considerably more labour. That, in the covering of the seed by means of harrowing, the work is also accomplished with more facility and dispatch, as by employing double implements of this kind, one turn may wholly finish the business. And that in the reaping, too, they have advantages, in allowing the number of reapers that are necessary to work with convenience, and without being in the way of each other. This, though a great advantage in some cases, is of less consequence since the mowing of grain is become more general.

But it is stated, that wet, clayey, or any stiff and tenacious loamy soils, where the under stratum is clay, should be ploughed as much as possible into ridges of much less size, in order that they may be kept in a state of dryness, suitable to the growth of the crops that are to be put upon them. Three or four feet, according to the degree of tenacity and wetness, may, in such sorts of land, be fully sufficient. And it is added, that in the counties of Essex and Hertford, on this sort of wet soils, three feet are found to answer the purpose in a very effectual manner. And that it has been observed in the Middlesex Agricultural Report, on the authority of much experience, that their superiority over ridges of greater breadths, for taking the water off without washing the land, is incontrovertible. That, in short, as there is much variation in lands of these kinds, the width and flatness of the ridges should be increased as they recede from the nature of clay or clayey loam, and approach that of sand, in order that a larger proportion of moisture may be preserved: while, on the contrary, as they are becoming more of a clayey quality, they ought to be narrower, and to have a more high and rounded form, that the discharge of injurious moisture may be more expeditious. In loamy soils they should be either broad and flat, or narrow and round, in some measure, according to the degree in which they approach the sandy or clayey soils. And that, in very wet clayey soils, where they rest upon a subsoil of some porous kind, great advantage in the way of drainage may often be obtained, by sinking the furrows so deep, as to reach it. But some persons, on these sorts of clayey soils, suppose the best breadth to be ten or twelve feet, as where they are narrower there is much disadvantage, though they keep the land drier. Also, in lands of the marshy or fenny kinds, as mostly approaching in some degree to the nature of these, the ridges should be made narrow, and rather round in their forms.

But that as the principal defect of lands of the sandy kind is that of parting with their moisture too readily, and of course becoming quickly in a state of too much dryness for the purpose of healthy vegetation, it is the most advisable to plough them into very broad ridges, or even in some cases quite flat, without the least degree of furrow being made; as, in this way, the moisture may be more effectually retained in such soils, to the great advantage of the crops which are grown upon them. But in the constructing of ridges on such soils as are of the boggy or mossy kinds, some attention is necessary in respect to their depth, and the proportion of wetness that may be present; as where they are thin, and have but little injurious moisture, they may be more broad and flat than where they are deep of moss, and more retentive of moisture: six or seven yards may, in general, be the best. It is observed, that even in the deeper sorts, long experience has shewn that, in the first instance, it is improper to make them too high or too narrow; as, in the former case, they throw the water off from their sides, without admitting it to penetrate their substance, the top of course gets too dry; while, in the latter, there is a loss of surface, from too many division furrows. The breadths already mentioned are found to be the best; and when the improvement is completed, the ridges appear like segments of wide circles, with a clean well-defined division furrow between each of them. The moisture is thus caused slowly to filtrate through the moss, rendered friable by lime, until it reaches the division furrows. It is generally necessary to clean these out before winter, and at the time the crop is sown, until the moss acquires solidity. This has been fully shewn in a paper, in the second volume of Communications to the Board of Agriculture. See the work.

And it has been remarked, that ridges in these soils are generally formed by the spade, the workmen beginning nearly in the middle of the part which is to form the ridge, only leaving the space of about eighteen or twenty inches, upon which the materials raised from the trenches on each side are deposited, so as to constitute the crown; and in this way, digging up and turning over narrow spits on each side, the workman proceeds till he comes to the division furrows, which are cut out and laid on the sides: in which way, the ridge, when completed, appearing as if done by the plough. And in the deeper mossy soils, especially of the more spongy kind, it is probable the breadth of the ridges may be increased with advantage, after they have collapsed and become sufficiently firm; as, by such means, they will be more suitable for being laid down to grass or sward, for the purpose of pasturage.

Further, in what respects the general disposition of ridges, where there is not a necessity of giving them any particular direction, either for the purpose of drainage, or other circumstances, they should be formed as much as possible in the direction of north and south; as, by that means, much advantage may be gained in the crops attaining maturity, and in becoming dry, from their having the more full influence of the sun and wind. And it has been remarked by Mr. Marshall, in his *Midland Economy*, that the sheaves, after grain has been reaped, should be set in the same direction, and not have an east and west position; as, in this case, the sheaves on the north side are many days later in being in a proper condition for being conveyed to the stack, than those on the south. From further experience, he is also convinced of the bad effects of ridges having an east and west direction; it having been found that corn, on the south sides of such as were not by any means high, shot into ear, and changed and ripened a week at least earlier than that on the north; and that at the time of reaping, the wheat on

## RIDGES.

the south sides was, in some patches, too ripe; while that on the north sides was, in many parts, absolutely in a green state.

But where the ridges are to be constructed in such lands as are hilly in their situation, or have much declivity, it is necessary that they be neither made too steep, nor have too much of a horizontal direction given them; being drawn in such a manner, as that they may have that sort of easy sloping direction, by which the water may be taken off in a gradual easy manner; as, in this way, there will not only be great advantage in the saving of labour in ploughing, nearly one-third less power in the team being sufficient; but the injury and inconvenience of heavy rains washing down the soil and manure will in a great measure be obviated. It has been stated by the author of the *Gentleman Farmer*, that in a hanging field, that had been carefully dressed with lime and dung for turnips, and in which the turnips were fairly above the ground, a heavy summer shower swept down the crop, together with the lime, dung, and a portion of the loose soil, leaving the land naked and exposed. Therefore, in the forming ridges in lands that have such situations, it has been well observed by the author of the *Agricultural Report of Perthshire*, that when the fields hang so much as to be accounted steep, the ridges ought neither to be drawn parallel to the bottom of them, nor at right angles, straight up and down; either of which would be inconvenient in the ploughing, and injurious to the soil; but they ought to be drawn diagonally. The great point is to understand in what direction this diagonal slope of the ridges ought to run. In this respect the tenants of Balgowan, in this district, are perfectly correct; and it is his wish that their example were followed by all farmers, whose land has a great declivity, of which there is a considerable proportion, not only in that, but in all hilly countries whatever. The form and direction of the ridges are, he thinks, contrived with such judgment, that the furrow (or, as lord Kaimes with more accuracy calls it, the furrow-slice) falls easily away from the mould-board, as well in ascending as in descending the field, which is the principal secret. There can be no more than two diagonal lines in any four-sided figure, which is generally the form of inclosures; and if you bring a sensible ploughman to each of the angles below, desiring him to look towards each of the opposite angles above, he will at once tell you which of these diagonal directions is easiest for himself and his horses, and will accordingly fix on that line by which the furrow, in ascending, will fall most readily into its place, having his right hand and the mould-board of his plough with a side-aspect to the bottom of the field. But, with the view of rendering this more obvious, suppose the field to have a steep descent and a southern aspect, the ridges are drawn from south-west to north-east; which is the case in the instance alluded to. Suppose, again, the field to have a northern aspect, the ridges are drawn in the same direction, but with this difference in ploughing, that you ascend south-west in the last case, whereas you descend south-west in the first. If the field fronts the east, you ascend north-west; or invariably four points forward from the slope of the field, in going up the hill. Besides the vast saving in respect to the power or strength of the team in this way, and that of the soil being less liable to be carried away by rains, by the running of the water in the furrows; where the ridges are made parallel to the bottom of the field, all the dexterity of a man and force of cattle that could be applied would be insufficient to turn every second furrow up against the hill.

It is remarked, that the expedient universally employed, according to the old system, in ploughing fields of this

kind, was either to plough with a double mould-board, or, if the mould-board were single, to plough only one furrow in going twice the length of the ridge; but most frequently the last. Both are, he thinks, bad husbandry. In the former method, you lose none of your time, indeed; but one half of your labour is lost by the latter. His principal objection, he is of opinion, holds equally against both. All the soil is, year after year, rolling downward; and in process of time, the upper part of the field will be peeled to the bone, and quite bare of soil, while a great bank is accumulating at the bottom, like a dunghill, composed of the richest land in the field; and withal, the furrows are laid so completely on their backs, that little benefit is derived from the manure, excepting it be laid on the surface the first year.

The same writer further states, that where a hill is to be dressed, in order to be laid down to grass, it ought to receive the latter furrow by going round in a spiral line, without ever turning the plough, beginning at the base, and ending at the top. This requires less labour, and is more beautiful. In preparing the ground for this last furrow, it may be ploughed diagonally, to keep the soil from tumbling down hill, as has been mentioned above, in respect to declivities: for this purpose, the surface of the hill may be divided into three or more sections. And it is remarked by a late practical writer, in addition, that, in this way, no more strength of team is required in ploughing such elevations than in that of ploughing on a level; while, where the soil is of the gravelly or sandy kind, the great inconvenience of the moisture going off too quickly is guarded against, by its being detained in the furrows. And the spiral furrow is, according to the first writer, the neatest method of finishing off a lawn, even of flat land, near a gentleman's house; as it brings the whole surface to an uniform appearance, and pleases the eye more than having the lawn striped with furrows.

In regard to such lands as are level, or have but little inequality of surface, the best general practice, it is observed by the author of a late work, is to form the ridges as straight and as regular in respect to breadth as possible; as, by having them crooked, and of irregular breadths, the water is not only liable to stagnate and injure the soil, but the friction in ploughing is greatly increased, and the furrow-slice is not so well laid over, being more disposed to fall back. And, besides, many unnecessary turnings are requisite, on account of the inequalities of breadth, by which much time is lost, as well as much trouble given to the ploughman in managing the plough while at work.

In some of the less improved counties in the northern parts of the kingdom, as Lancashire, and those adjoining it, the ridges on the old lands are often narrow, crooked, and very ill laid out, being for the most part too much rounded in the middle parts, and in the form of butts, which are the states in which they are at the present time, few or no attempts having been made to alter them in any way. However, from the nature and depths of the soils, it would not appear that there would be any danger or difficulty in doing it; though this may be the case in some other situations, where it ought to be attempted with proper caution. In some parts of the above district, as that of the field, the term *farring* or *furrowing* is often made use of, instead of that of ridge.

*Method of Levelling and Straightening old Ridges.*—In such kind of land as has been long in a cultivated state, high, crooked, and irregular ridges are frequently met with, that often become necessary to be altered, so as to be rendered more straight and level. This, though apparently simple,  
is

is a matter of more difficulty and trouble, and which demands more knowledge and care in its execution, than is commonly supposed by persons unacquainted with the business. Various obstacles have been thrown in the way of this sort of improvement by farmers in different districts. By some the expence is considered as very great, while others oppose it on the ground of the injury done to the land for some years afterwards. And according to the Agricultural Report of the county of Perth in Scotland, the objection made by some farmers in the Carse of Gowrie is this: in the action of levelling ridges, that have been, time immemorial, raised high in the crown, much soil is brought up, which for ages had neither seen the sun nor smelled the air. This, like most other soils, which has been so long and so deep buried, is very unproductive at first, and blasts all their expectations. It is perfectly consonant to the process of nature, the writer supposes, that this should, in some measure, happen; and, as far as it has any weight, is an argument not only against levelling, but against straightening the ridges of such land. But was not, he asks, every particle of that soil, which is so much reprobated, on the surface of the ground before the ridges were so raised by the hand of man? Was not this very soil, at that time, as good as any soil in the field? Nay, was it not much more fertile before it was buried in the middle of the ridge, than the *new* soil, which the ploughman was digging up year after year, out of the sterile furrow, to assist in gradually raising his ridge higher? Every man must answer in the affirmative. If you therefore bring back your land nearly to the level in which the hand of nature left it, you will find the very soil, which had been fertilized by the deciduous parts of plants, from the creation, until it came into cultivation; the soil which Providence intended for the production of grain for the use of man, this soil has not surely lost its fertility, although that fertility has lain long dormant by its being covered up in the bowels of the earth, and removed from the benign influence of heaven. The fertility of a soil cannot be exhausted by any other means, but by over-cropping. It may be suspended, as in this instance, but not annihilated. Restore the soil to its native place, and to that influence of which it was deprived, and it will soon become equally productive as at first. It is not pretended that its fertility will be exerted all at once. Clay is a stubborn soil: it is neither so easily stimulated by manure, nor by the benignity of the atmosphere, as other soil. It requires time and labour and expence to set it in motion; but when moved it retains its powers longer and makes very ample returns. And in addition to these observations, vast benefits must in many cases result from bringing ill-formed ridges into a proper situation for the advantageous culture of crops upon them.

With regard to the time or season for the execution of this sort of work, it has been remarked that the most suitable period for accomplishing it where the plough is employed, is when the land is undergoing a course of repeated ploughings, as in the case of a fallow; as under such circumstances the more elevated parts of the field may be ploughed over as often, and in such directions, as is most suitable for bringing them into a level state. Where the ridges are not raised to any very considerable height in their middles, but badly formed in other respects, they may sometimes be readily brought into proper order by being split, or cloven down occasionally; a mode which is performed by beginning at the furrows and terminating at the crown or middle of the ridge, so that the former furrows become the crowns, and the new furrows are made in the middle of the old ridges, which being filled by a furrow from each side, has the tendency of soon bringing them into a more equal

and level form. But that in cases where the soil is of the light, gravelly, or open and mellow kind, the plough may be conveniently employed in levelling the ridges, without producing any injury of consequence to the crops that may afterwards be put upon the land. It is proper, however, even in lands of these kinds, to use such caution in performing the operation, in order to avoid the injury that might be caused by too large a proportion of the under soil being brought to the surface in different parts of the ground, and in that way rendering it less productive in crops than it was before.

It has been contended, however, by Dr. Anderson, in the first volume of his Essays, that where this sort of work is done by such implements as are contrived for expeditiously bringing high ridges to this situation, as ploughs, harrows, drags, &c. the farmer of necessity buries all the good mould that was on the top of the ridges in the old furrows; by which he greatly impoverishes one part of his field, while he too much enriches another; inasmuch, that it is a matter of great difficulty, for many years thereafter, to get the field brought to an equal degree of fertility in different places: which makes it impossible for him to get an equal crop over the whole of his field by any management whatever: and he has the mortification frequently, by this means, to see the one half of his crop rotted by an over-luxuriance, while other parts of it are weak and sickly, or one part ripe or ready for reaping, while the other is not properly filled; so that it were, on many occasions, better for him to have his whole field reduced at once to the same degree of poorness as the poorest of it, than have it in this state. An almost impracticable degree of attention, in spreading the manures, may indeed in some measure, he thinks, get the better of this disease: but it is so difficult to perform this properly, that he has frequently seen fields that had been thus levelled, in which, after thirty years of continued culture and dressings, the marks of the old ridges could be distinctly traced when the corn was growing, although the surface was so level that no traces of them could be perceived when the corn was off the ground. But this, he remarks, is a degree of perfection in levelling that cannot be usually attained by following this mode of practice, and therefore it is but seldom seen; for all that can be expected to be done by any levelling machine is to render the *surface* perfectly smooth and *even* in every part at the time that the operation is performed: but as in this case the old hollows are suddenly filled up with loose mould to a great depth, while the earth below the surface, upon the heights of the old ridges, remains firm and compact, the new-raised earth, after a short time, subsides very much, while the other parts of the field do not sink at all; so that in a short time the old furrows come to be again below the level of the other parts of the field, and the water, of course, is suffered in some degree to stagnate upon them, inasmuch that in a few years it becomes necessary once more to repeat the same levelling process, and thus renew the damage that the farmer sustains by this pernicious operation. He therefore thinks that on these accounts, if the farmer has not a long lease, it will be found, in general, to be more for his interest to leave the ridges as he found them, than to attempt to alter their direction: and if he attends with due caution to moderate the height of these old ridges he may reap very good crops, although, perhaps, at a somewhat greater expence of labour than he would have been put to upon the same field, if it had been reduced to a proper level surface, and divided into straight and parallel ridges. However, where a man is secure of possessing his ground for any considerable length of time, the advantage that he will reap from having level and well laid

## RIDGES.

out fields are so considerable, as to be worth purchasing if it should even be at considerable expence. But the loss that is sustained at the beginning by this mechanical mode of levelling ridges, if they are of considerable height, is so very great, that it is, perhaps, doubtful if any future advantage can ever fully compensate it. On these grounds he rejects the use of machinery in these operations, and recommends the method described below as being more efficacious and successful. There have, however, of late been many valuable machines contrived for the purpose of accomplishing the work in an easy and cheap manner, and which have been found to answer in practice. An implement of this sort has been described under the head machine. See *MACHINE Land Levelling*.

But where the lands are of the clayey, loamy, or tenacious wet quality, there is much greater difficulty, as well as greater attention required, in levelling down and changing the forms of the ridges, as it frequently happens that in such soils, after the earth from the crowns has been removed in order to render them level, a coarse, unfriendly, stiff soil is brought up, as has been seen above, that requires a great length of time and much amelioration to bring into a state capable of supporting good crops of any sort of grain. In these cases and sorts of soils, in the straightening and bringing down the ridges on the coarse lands in the northern parts of the island, the author of the Perth Agricultural Report advises it as proper to begin the operation by removing the made or ameliorated soil on the crown of the ridge to one side, which may, he thinks, be done by two or three ploughings in one direction, turning the furrow always one way. This is easier than doing it with the spade. Then such a quantity of the buried soil may be cast with the spade from the crown of the ridge, as will fill up the furrows at pleasure; and, lastly, the ameliorated soil may be spread over the surface of the whole. If it is not thought enough to save the ameliorated soil on the crown of the ridge alone, first one side of the ridge may be taken, and then the same process repeated on the other; by which means almost all the wrought soil may be kept on the surface. A good summer fallow and a hearty dose of lime, and the mixture of wrought mould, will reanimate the new soil, and restore its vegetative power to its primitive state; and a very few seasons will naturalize the whole soil, while the farmer has the advantage of straight ridges, moderately raised. Some, however, think that this business may be best performed by the spade, though it is now obviously impossible in many situations from the vastly increased expence of labour. Where this mode is to be employed, it is advised by Dr. Anderson, in his *Essays on Agriculture and Rural Affairs*, to let a number of men be collected, with spades, according to the extent of work, and then set a plough to draw a furrow directly across the ridges of the whole field intended to be levelled. Divide this furrow into as many parts as labourers, allotting to each a ridge or two, more or less, according to the number and height of the ridges, and other circumstances. Let each of the labourers have orders, as soon as the plough has passed that part assigned him, to begin to dig in the bottom of the furrow that the plough has just made, about the middle of the side of the old ridge, keeping his face towards the old furrow, working backward till he comes to the middle of the old ridge, going deeper as he advances, suitable to the height he has to bring down; then let him turn towards the other furrow, and repeat the same on the other side of the ridge, so as to leave the bottom of the trench he has thus made across the ridge, entirely level, or as nearly so as possible. When he has finished that part of the furrow allotted to him, which

the plough has made in going, let him then go and finish in the same manner his own portion of the furrow which the plough makes in returning. In this manner each man performs his own task through the whole field, gradually raising the old furrows as the old heights are depressed.

And the old furrow ought to be raised to a greater height than the middle of the old ridges, so as to make allowance for the subsiding of that loose earth. And the operation is thus finished at once. He recommends the making of these temporary or cross ridges 40 or 50 yards broad at least: for although some time will be lost in turning at the ends of the broad ridges, the advantage that is reaped by having few open furrows is more than sufficient to counterbalance this loss: and in order to moderate the height that would be formed in the middle of each of these great ridges, it will always be proper to mark out the ridges, and draw the *furrow* that is to be in the middle of each, some days before you collect your labourers to level the field, to prevent any hurry or loss of labour in the future operation of levelling. The field will thus be reduced at once to a proper level, and the rich earth that formed the surface of the old ridges will still be kept on the surface of the field to be formed into new ridges. And the same writer adds, that the direction of the ridges, as noticed before, ought to be north and south, if the field will permit, by which means the east and west sides of the ridges, dividing the sun equally between them, will ripen at the same time. Also further, that when the soil is so wet as to require the raising of the ridges, they ought to be made twelve feet wide, and twenty inches high, and to be preserved always in the same form, by *casting*, that is, by ploughing two ridges together, beginning at the furrow that separates them, and ploughing round and round till the two ridges be finished. The separating furrow is indeed raised a little higher than the furrows that bound the two ridges, but at the next ploughing that inequality is corrected by reversing the operation, which is easily done.

And in regard to the expence of the different methods, the following statements are given by the same writer, which, though far below the present price of labour, may furnish the means of calculation to the improver. Supposing the price of labour in Scotland to vary in different places from sixpence to one shilling, and that the medium price be fixed at nine-pence a day; and that the hire of a plough, with four horses and two servants (for so many, in general, will be requisite to labour properly ground in the condition that this is supposed to be in), varies in like manner from three to five shillings *per* yoking, and that the medium price of this be called four shillings; in this case the comparative expence of levelling, by these two different modes, would be as follows.

### Expence of Levelling by Spade.

	£	s.	d.
For wages to eleven labourers one day, at nine-pence each	0	8	3
For the hire of a plough 2½ yokings, at four shillings each	0	10	0
Total expence of one day's work	0	18	3

### Expence of Levelling by Plough and Harrows.

For two yokings and a half of a plough, as before	0	10	0
For harrowing ditto, supposed at one-fourth of the ploughing	0	2	6
Total	0	12	6

## RIDGES.

Total for once ploughing, &c.	£	s.	d.
	0	12	6
The same five times more repeated	3	2	6
Total expence of levelling by plough and harrow	3	15	0
Total expence of levelling by the spade	0	18	3
Difference	2	16	9

But another method practised by Mr. Paterfon of Castle-huntley is, according to Dr. Robertson, first to open up with the spade a trench of about ten feet broad, from end to end of the field, in the same direction that the ridges are to be made. The upper surface of the ten-feet trench is laid upon one side, to be removed afterwards. Then the under soil of this trench is levelled and dressed by the spade and wheel-barrow, or carts, if necessary, at the same time giving the land a gentle fall at both ends, to enable the water to run off in the furrows towards the main drains. When this under soil has got its proper shape, he marks off another ten-feet trench, and with the spade throws the upper soil of the second trench on the new-formed under soil of the first trench, so as to cover it completely and equally: and so on through the whole field. The upper soil of the first trench was carried round in carts, and laid on the under soil of the last trench. The appearance of the field was then regular, rising in the middle and falling at both ends. He recommends ridges eighteen feet wide. The whole expence is supposed to be 8*l.* an acre. And it is observed in the third volume of the Farmer's Magazine, that ridges in enclosed lands are capable of being straightened with profit, or at least without loss, by wearing down the high ridges by the preceding crops, so as not to leave too much to the fallow, which is by turning one field at least into turnip or fallow every year until the whole is gone over. For as the land is ploughed and harrowed over and over in all directions, until it is brought to a close fine mould, the ridges may then be laid off just as the farmer pleases, without any loss. But that in straightening without this previous operation, the loss cannot be calculated. The advantages are therefore obvious to every man.

A writer in the fifth volume of the same work also observes, that in wet clayey soils, where the operation is undoubtedly most difficult to execute, he has accomplished the business with facility in this way. On dry soils, very little judgment or skill is required to do it, with safety to the ground, and advantage to the occupier. He states, that in 1794 he fallowed and straightened a field of about thirty acres, which had been oats the preceding year. The soil was a wet clay, and the ridges were very unequal in breadth, from ten to thirty feet, intermixed with *butts* or *guffets*, which are always detrimental to such lands, as they occasion the ploughs, &c. to turn often upon the other ridges, by which means the prints or marks of the horses' feet are left unfilled up. The first operation consisted in cleaving down the ridges. The field was then ploughed across, and thoroughly harrowed; but before the broad ridges could be brought to a level, several ploughings were necessary, which were accordingly given. The season, however, was far advanced before these necessary operations could be effected; and, as lime could not at this time be applied with advantage, he was under the necessity of laying it up in heaps, in an adjacent grass field, so as it might be expeditiously laid on whenever the field was straightened. The next consideration was, to form the ridges in such a manner as to prevent water from stagnating upon the ground. With this view, he run

them partly east and west, and partly north and south, as the level would admit. When the ridges were thus formed and gathered up, the lime was applied, and a good cross-harrowing given, in order to fill up the furrows. And it being now the latter end of October, and the weather very wet, he thought it advantageous, in giving the feed furrow, to yoke the horses in line, and not a-breast, as is the usual practice. The whole field was sown on the 6th and 7th of November, and the braird appeared about the beginning of December. The weather having been wet for some days after the wheat was sown, it appeared rather thin in March, but always retained a dark green colour. It improved much during the summer months; and at harvest, turned out as good a crop as ever he saw upon such poor wet soil, the produce *per* acre being from thirty-two to thirty-four Winchester bushels of good marketable grain. Next year he ploughed the field again, and sowed one half with oats, and the other half with peas, both which were as good crops as could be expected. Perhaps it may be thought that he should have sown grass seeds among the wheat; but it is his opinion, that when ridges have been altered, a second fallowing is necessary before the field can be profitably laid down to grass. Last year he straightened a field in the above-mentioned way, which has answered his expectations to the full. It was sown with grass seeds, which at present promise well. He concludes by observing, that the advantages resulting from the practice of straightening ridges are obviously many and great. More work is performed both by plough and harrows, and to better purpose, in a given space of time: much seed too is saved; for when the ridges are at or below eighteen feet in breadth, which they ought never to exceed, two casts will suffice: whereas, in their former state, three, or even four casts, will be necessary in some parts, and in others one will be too much. Straightening ridges, and making them all of one size, also greatly furthers harvest work, as it is well known, that shearing is more expeditiously performed upon them, than upon those that are unequal with one another, or such as are broad at one end and narrow at the other. The last, though not the least advantage, which he shall notice at present, is, that wheat is not so apt to canker upon straight as upon crooked ridges. He will not now inquire how this comes to be the case; but leave it to the consideration of those who delight in abstract philosophical researches: it is sufficient for him to be assured, from experience, that it is so. The business of straightening and levelling ridges, in many situations, certainly demands much more attention than it has hitherto met with by the farmer and land proprietor.

But besides these modes of ridging, which are necessary in laying out lands for the purpose of tillage, there are others that become requisite in consequence of the growth of particular sorts of crops, and the particular methods of husbandry by which they are cultivated. Thus we have one, two, and three, or more *bout* ridges, according as the crops are grown to most advantage, on one or other of these sorts of small ridges, or as they suit the different sorts of tools by which they are put into the ground. Some other local modes likewise occur in tillage districts, of forming small ridges, for the cultivation of different kinds of crops. See **TILLAGE**.

**RIDGES**, in *Gardening*, portions of ground laid up by means of the spade in a narrow strip, to the height of one, two, or more feet, for the purpose of receiving the benefit of frosts and the influence of the atmosphere, and thereby become more mellow, light, and friable, as well as more fertile and productive. See **RIDGING**.

**RIDGE-Work**, in *Agriculture*, that sort of tillage which is executed

executed in the ridge method, or by raising the surface of the land into some kind of ridges.

*RIDGES of a horse's mouth*, are wrinkles or risings of the flesh in the roof of the mouth, running across from one side of the jaw to the other, with interjacent furrows.

It is commonly in the third or fourth ridge that the farriers strike with the horn, in order to bleed a horse whose mouth is overheated.

*RIDGIL*, in *Rural Economy*, a male sheep, in which the testicles do not come properly down into the scrotum.

*RIDGIL Lambs*, such as have none, or only one testicle, in the scrotum or cod. There is often great trouble and danger in these sorts of animals being mixed with other sheep stock, as they not only tease the ewes, but frequently injure them. The lambs should, of course, always be cut while young, as from six to ten or twelve weeks old, though the operation may be performed with safety at a much later period, and even when a year or more old. Mr. Marshall, in his *Norfolk Economy*, describes the manner of doing it in this way, where only one of the testicles had come down or entered the cod. Having cut off the end of the scrotum, bag, or cod, the testicle was drawn out in the usual manner of gelding. The other was taken out at the side contrary to that on which the palpable testicle was placed. In performing which, the lamb is laid flat on its side upon the ground, being held in that position by one man, keeping its neck and fore legs close down, while another stretches it out by drawing the hind legs backwards, keeping them tight down, so that the animal cannot stir. The operator then clips off a small patch of wool, about the size and shape of a duck's egg, close below the loin, and in the middle between the huckle and the short ribs; after which he makes an incision, sufficiently wide to admit his forefinger, with which he searches for the stone and brings it out, disengaging it from the tunic or coat in which it is enclosed by a knife, drawing out the cord or string. The orifice after this is carefully sewed up, and the wounded parts anointed with elder or some other ointment.

And it is stated as remarkable, that the concealed testicles all laid on the same side, namely the right side; the contrary side to that on which females are cut, in the cases he had the operation performed in. And that in one the operation was rendered difficult by the testicle being very small, and braced up close to the vertebrae. It is likewise added, that the palpable testicle being priorly extracted, increases the difficulty of the operation, as the person who performs it does not know which side to cut on, and is sometimes obliged to cut on both before he finds the concealed testicle.

This is a nice operation, which requires much care and attention in the person who performs it.

*RIDGING of Ground*, in *Gardening*, the practice of throwing it up into high ridges in order to lie fallow in winter, &c. to mellow, and improve in its quality and fertility.

It may be noticed, that this is a work of great utility in the kitchen garden, as well as in other parts, but more especially in stiff heavy soils, and cold wet lands. It is accomplished by trench-digging the ground over, laying the earth of each trench in a raised, rough ridge, lengthways, that by thus lying as high, open, and hollow as possible, it may meliorate and fertilize more effectually by the weather during the winter. And it receives further improvement from the levelling it down again, which is expeditiously effected, for the reception of the intended seeds, plants, roots, &c. which breaks, divides, and pulverizes the earth still more effectually.

And this sort of ridging is generally performed, either in

the latter end of autumn, or any time in winter, or early in the spring, as the ground is the most vacant at those seasons, and not generally immediately wanted for any principal sowing or planting.

This sort of work is executed by beginning at one end of the plat of ground, and digging out a trench one or two spades in width, and a full spade's depth, removing the crumbs from the bottom, in the lengthways across the ground, and wheeling the earth to the finishing end, to be ready to fill up the last trench: so marking out a second trench close to the first, of the same width, then proceeding in the trenching and ridging, previously paring the top of the second trench, with all weeds, rubbish, or dung thereon, if any, into the bottom of the first, and then digging the ground of the second along regularly, the proper width and depth as above; turning the earth spit and spit into the first open trench, laying it in a raised ridge lengthways thereof, without breaking it fine, so that it may lie somewhat rough and hollow, according as the nature of the soil may admit: proceeding thus with another trench in the same manner, and continuing the same with the whole, trench and trench, to the end of the plat of ground; filling up the last trench with the earth of the first opened, laying it now ridgeways, as in the preceding trenches.

But in the work of levelling down ridged ground, as wanted, it should proceed regularly, ridge and ridge, longways, levelling the earth equally to the right and left, loosening any solid parts, and breaking all large rough lumps and clods moderately fine; forming the whole in an even regular surface, in order for sowing and planting, as required.

And in general, it is not advisable to lay down more than can be sown the same or next day, while the surface is fresh stirred, especially in broad-cast sowing and raking in the seed, as, most generally, all tolerably light mellow soils are more yielding to the rake while the surface is fresh moved; or before rendered wet by rain, &c.: or very dry and hardened in the top earth by the sun, air, and winds, in dry weather, in the spring months, &c.; and likewise for sowing seeds by bedding in and covering in with earth from the alleys, &c. or with earth raked off the beds for that purpose, it would generally be most successful to perform it in a fresh stirred surface; though it is not so material in drill sowing; and besides, when seeds are committed to the earth, while it is in a fresh turned up surface, especially in a dry season, they are more forwarded in a free regular germination than in ground that has lain some time after digging or levelling down. Though some grounds, of a wet, or heavy, stiff nature, sometimes require to lie a few days after digging or levelling down, in order for the rough cloddy surface to mellow in some degree, either by drying a little, or by having a moderate rain, or sometimes both, to meliorate the lumpy clods, pliant to the rake, in the case of broad-cast sowing, and raking in the seed.

*RIDGING-up*, in *Husbandry*, a term used to signify the practice of laying up the mould or soil to the rows of particular sorts of crops, as those of the pea, potatoe, turnip, cabbage, and other similar kinds. It also implies the laying up land or earth in such a manner as that it may receive the most full and perfect benefit and influence of the atmosphere, and in consequence become in a mellow and pulverized state. It is often very necessary in stiff lands.

*RIDGLET*, in *Agriculture*, a provincial word, used to signify a small ridge, especially when raised by baulking or ridging up with the plough.

*RIDGLING*, in *Rural Economy*, the male of any beast

that

that has been partially castrated, or which is not properly formed in the cod.

RIDICULE, in *Ethics*, is commonly used in the same sense with irrision; and has for its objects the absurdities and misfortunes of mankind. The latter, however, are very improper objects of ridicule, whose province should extend only to the carelessness, inconstancy, humour, affectation, impertinence, and in short all the lesser follies and imperfections of mankind. Such are generally the subjects of Horace's Satires; and Dr. More observes, that irrision, which is the parent of ridicule, was the original of satire.

Dr. Campbell (Philos. of Rhet. vol. i.) observes, that ridicule is not only confined to questions of less moment, but is fitter for refuting error than for supporting truth, for restraining from wrong conduct, than for inciting to the practice of what is right. It is not properly levelled at the *false*, but at the *absurd* in tenets; and it is not the criminal part of misconduct which it attacks, but that we denominate silly or foolish. With regard to doctrine, it is not falsity or mistake, but palpable error or absurdity (a thing hardly confutable by mere argument) which is the object of contempt; and consequently those dogmas are beyond the reach of cool reasoning which are within the rightful confines of ridicule. This statement is obviously inconsistent with the mode of arguing adopted (very improperly, as we conceive) by those who make ridicule, or raillery, the test of truth. To this class we may refer a noble writer, who, in his "Characteristics" (vol. i.) after alleging that truth may bear all lights, observes, that *one* of those principal lights or natural mediums, by which things are to be viewed, in order to a thorough recognition, is *ridicule* itself, or that manner of proof by which we discern whatever is liable to just raillery in any subject. So much, at least, is allowed by all, who at any time appeal to this criterion. His advocates, however, have asserted, that unjust representations have often been given of the positions which he has maintained in his "Essay on the Freedom of Wit and Humour," and it has been said, particularly in the "General Dictionary," that he was very far from vindicating a vague, indecent, and boundless ridicule, or inclined to employ his wit and humour otherwise than under certain restrictions, and when particular occasions called for and justified it. Although it be allowed, that his lordship has been in some instances misunderstood and misrepresented, and he has written in a manner so inaccurate and unguarded, as to have subjected himself to just animadversion and censure, Dr. Brown, in his "Essays on the Characteristics," has animadverted on his lordship's reasoning; and with great ingenuity contended, that though ridicule is a species of eloquence, reason alone is the detector of falsehood, and the test of truth; that ridicule can never pretend to this character; that it is one of the most powerful engines by which error can be maintained and established; and that its proper object is folly of conduct, and chiefly affectation. Other writers have defended his lordship, among whom we may reckon the Rev. Mr. Charles Bulkeley, an ingenious and learned dissenting minister. In a work ascribed to Mr. Ramsay, the painter, the author has attempted to shew, that ridicule is of two kinds, and that it may be applied to opinions as well as to manners. The usual objects of ridicule are, indeed, certain improprieties and peculiarities of character and conduct, and to assert, in general, that it is the test of truth, is advancing a false position. Reason is undoubtedly the genuine and proper test of truth. Nevertheless, ridicule may in some cases be justly applied to opinions. There are tenets so flagrantly absurd, that it is not easy to refrain from viewing them in the light of humour and raillery, and perhaps the best way of exposing them may be to display

them in that light. Nevertheless, it must be acknowledged, that ridicule, when applied to grave and important subjects, is a very dangerous weapon; that it ought to be adopted with the utmost discretion, and that it has often been made use of in an improper manner.

With regard to conduct, says Dr. Campbell, we may discover to what kind ridicule is applicable, by directing our attention to the different departments of tragedy and of comedy. In the last it has a mighty influence: but into the first it never legally obtains admittance. Those things which principally come under its lash are awkwardness, rufficity, ignorance, cowardice, levity, foppery, pedantry, and affectation of every kind. But against murder, cruelty, parricide, ingratitude, or perfidy, to attempt to raise a laugh, would shew such an unnatural insensibility in the speaker, as would be excessively disgusting to any audience. To punish such enormities, the tragic poet must take a very different route. It should be carefully remembered, says our author, that where nothing reprehensible, or supposed to be reprehensible, either in conduct or sentiment, is struck at, there is properly no satire (or, as it is sometimes termed, pointed wit), and consequently no ridicule. We may here observe, that the words "banter" and "raillery" are used to signify ridicule of a certain form, applied, indeed, more commonly to practices than to opinions, and oftener to the little peculiarities of individuals, than to the distinguishing customs or usages of sects and parties. The only difference in meaning between the two terms is, that the first generally denotes a coarser, the second a finer sort of ridicule; the former prevails most among the lower classes of the people, the latter only among persons of breeding. Dr. Campbell, after remarking that an air of ridicule in disproving or dissuading, by rendering opinions or practices contemptible, hath occasionally been attempted with approbation by preachers of great name, suggests the absolute necessity, in the use of it, of the greatest care and delicacy, that it may not degenerate into a strain but ill adapted to so precious an occupation.

Our author cites the authority of Aristotle in favour of the general principles with regard to the subject of ridicule which he has endeavoured to establish. "The ridiculous," says the Stagyrite, "implies something deformed, and consists in those smaller faults, which are neither painful nor pernicious, but unbefitting: thus a face excites laughter, in which there are deformity and distortion without pain." Aristotle here speaks of ridicule, not of laughter in general; and not of every sort of ridicule, but solely of the ridiculous in manners, of which he has, in few words, given a very apposite description. Laughter is not his theme, but comedy and laughter, only so far as comedy is concerned with it; and the concern of comedy reaches no farther than to that kind of ridicule which relates to manners. For an account of Hobbes's theory of laughter and Dr. Campbell's objection to it, see LAUGHTER.

On the subject of laughter, Dr. Hartley (Obs. on Man) remarks, that young children do not laugh aloud for some months. The first occasion of doing this seems to be a surprise, which brings on a momentary fear first, and then a momentary joy, in consequence of the removal of that fear, agreeably to what may be observed of the pleasures that follow the removal of pain. This may appear probable, inasmuch as laughter is a nascent cry, stopped of a sudden; and also because, if the same surprise, which makes young children laugh, be a very little increased, they will cry. As children learn the use of language, they learn to laugh at sentences or stories, by which certain alarming notions and expectations are raised in them, and again dissipated instantaneously.

taneously. Children, and young persons, are diverted by every little jingle, pun, contrast, or coincidence, which is level to their capacities, even though the harshness and inconsistency, with which it first strikes the fancy, be so minute, as scarcely to be perceived. And this is the origin of that laughter which is excited by wit, humour, buffoonery, &c. The most natural occasions of mirth and laughter in adults seem to be the little mistakes and follies of children, and the smaller inconsistencies and improprieties, which happen in conversation in the daily occurrences of life; inasmuch as these pleasures are, in great measure, occasioned, or at least supported, by the general pleasurable state, which our love and affection to our friends in general, and to children in particular, put the mouth and body into. For this kind of mirth is always checked where we have dislike; also where the mistake or inconsistency rises beyond a certain limit; for then it produces concern, confusion, and uneasiness. This account of the original of laughter, and also of its salutary effects which the author mentions, both with respect to the body and mind, is inconsistent with Hobbes's theory, to which we have above referred. The laughter of pride and contempt, and the ridicule connected with it, are very different, not only in their origin, but in their influence.

**RIDICULE**, in a *Comedy*. See **COMEDY**.

**RIDICULI ÆDICULA**, or the *Chapel of Laughter*, in *Roman Antiquity*, was a building erected at Rome, about two thousand paces beyond the gate Capena, in memory of the flight of Hannibal from the siege of the city, on account of the ruin and tempest that befel him on that occasion. The Romans, in ridicule of his flight, built and consecrated this chapel.

**RIDING**, a corruption of *trithing*, a division of Yorkshire, of which there are three; viz. the East-riding, West-riding, and North-riding.

In indictments, in that county, it is necessary that the town and riding be expressed. See **REGISTER**.

**RIDING Academy**. See **ACADEMY** and **MANEGE**.

An academy for riding was founded in this country, by king William III. See **RIDE**.

**RIDING Armed**, with dangerous and unlawful weapons, is an offence at common law. (4 Inst. 160.) By the statute 2 Edw. III. cap. 3. none shall ride armed by night or day, to the terror of the people; or come with force and arms before the king's justices, &c. doing their office, upon pain to forfeit their armour, and suffer imprisonment at the king's pleasure; and a fine may be set upon them by the justices, by 20 Ric. II. cap. 1. And no person can excuse the riding armed, in public, by alleging that he wears armour for his defence against an assault; but men may wear common arms, according to their quality and the fashion, and have attendants with them armed agreeable to their characters: also persons may ride or go armed to take felons, suppress riots, execute the king's process, &c. 3 Inst. 162.

**RIDING Cast**, in *Husbandry*, a term used by the farmers for a particular method of sowing their grounds, by making two casts upon the ground at the same time. This is not much used, but it is a quicker way than the double cast, which is the method now most used. Plot's Oxfordshire, p. 251.

**RIDING-Clerk**, one of the six clerks in chancery, who in his turn, for one year, keeps the enrolment-books of all grants that pass the great seal that year. Blount.

**RIDING-Bitts**, in *Ship Building*, are the largest bitts in a ship, and those to which the cable is fitted when she rides at anchor.

**RIDL**, in *Geography*, a town of Austria; 10 miles S.S.W. of Aigen.

**RIDLEY, NICHOLAS**, in *Biography*, an eminent English prelate, and martyr to the cause of the reformed religion, descended from an ancient family in Northumberland, was born early in the 16th century. As he exhibited early proofs of good natural abilities, he was placed in a grammar-school at Newcastle-upon-Tyne, in which he made such progress, that he was taken from thence and entered of Pembroke-hall, Cambridge. This was about the year 1518. In 1522 he was admitted to the degree of B.A.; and in 1524 he was elected a fellow of his college. In the following year he commenced M.A.; and having been ordained priest, he went, for farther improvement, to the Sorbonne at Paris; and from thence to Louvain; continuing on the continent till the year 1529. He had been brought up, and continued a zealous Papist; but on his return home, he applied with great diligence to the reading of the scriptures, as the safest guides in his theological studies. In 1533 Mr. Ridley was chosen senior proctor of the university; and while he continued in this office, the point of the pope's supremacy was brought before the university, to be examined upon the authority of scripture. No one was better qualified to give an opinion on this subject than Mr. Ridley; and after much public disputation, the university came to the following resolution: "That the bishop of Rome had no more authority and jurisdiction derived to him from God, in this kingdom of England, than any other foreign bishop;" and this was officially signed by Mr. Ridley, as well as by the vice-chancellor and the other proctor. In the year 1536, his well-known learning and talents procured him a powerful patron in archbishop Cranmer, who took him into his family, and made him his chaplain. He had, probably before this, abandoned the principles in which he had been educated; and being, in 1538, presented by the archbishop to the vicarage of Herne, in East Kent, he preached certain doctrines attached to the reformation, but nevertheless still adhered to the doctrine of transubstantiation. Among other converts whom he made to his own opinions was lady Fiennes, who proved a distinguished ornament to the cause which she adopted. To excite or enliven the devotion of his parishioners, he had the "Te Deum" sung in English, which was afterwards made the subject of an accusation against him. In 1539, when the act of the six articles was passed, he bore his testimony against it, though he himself was not likely to be affected by the penalties of the statute. In 1540 he went to Cambridge, and proceeded doctor in divinity; and soon after he was chosen to the mastership of Pembroke-hall. About the same time he was, through the influence of the archbishop, nominated chaplain to the king; and this honour was speedily followed by his collation to a prebendal stall in the cathedral church of Canterbury. In this city, when his duty called him to preach, he endeavoured with all his talents to expose to the people the abuses of Popery; which gave so much offence, that charges were exhibited against him for preaching contrary to the statute of the six articles. The attempt, however, of involving him in the penalties of the law, completely failed. Gardiner, bishop of Winchester, next endeavoured to entrap him; and articles were exhibited against him before the justices of the peace in Kent, and afterwards before the king and council, which charged him with preaching against auricular confession, and with directing the Te Deum to be sung in English. The accusation was fortunately referred to Cranmer, by the king, who immediately crushed it, much to the mortification of Dr. Ridley's enemies. About the year 1545

## RIDLEY.

he began to examine the doctrine of transubstantiation, which he and his friend and patron, Cranmer, rejected as unscriptural. Towards the close of the year he was appointed prebend of St. Peter's, Westminster. It 1547 he was promoted to the bishopric of Rochester; and in the following year he was employed in reforming the liturgy, in conjunction with Cranmer, five other prelates, and some learned divines; and in 1549 he was appointed one of the commissioners empowered to search after all Anabaptists, heretics, and contemners of the book of common prayer. In this character he was involved in the foul reproach of having contributed to bring to the stake Joan Bocher, and others. (See CRANMER.) That he did this from conscientious motives, there can be no doubt; but he ought to have investigated the principles, before he proceeded to the horrid act of persecution; and having a mind open to conviction, he would soon have found that no tenets, inculcated by the mild and holy Jesus, would lead to the infliction of corporal punishment for the sake of curing mental error. He more than once opposed the unreasonable commands and wishes of those in power; and would no doubt, in the case of Bocher and others, have done so too, had he felt it his duty.

The bishop of Rochester was one of the commissioners appointed to sit in judgment on the cause of Bonner, bishop of London; and by him the sentence of deprivation was pronounced against the prelate. This was in the reign of Edward. In that of Mary, as we shall see, ample revenge was taken of him. Ridley succeeded to the bishopric of London in the year 1549-50, when the bishopric of Westminster was suppressed as a distinct see, and united to that of London. Ridley's conduct towards his predecessor Bonner, and his family, after taking possession of the episcopal palace, was honourable to his integrity and benevolence, of which the following facts are sufficient proofs. He took care to preserve from injury the goods, &c. belonging to Bonner, allowing him full liberty to remove them when he pleased. Such materials as Bonner had purchased for the repair of his house and church, the new bishop employed to the uses for which they were designed; but he repaid him the money which he had advanced for them. He took upon himself the discharge of the sums which were due to Bonner's servants for liveries and wages; and that the mother and sister of that prelate, who lived near the palace at Fulham, and had their board there, might not be losers in consequence of his promotion, he always sent for them to dinner and supper, constantly placing Mrs. Bonner at the head of the table, even when persons of high rank were his guests.

Soon after his translation to the see of London, bishop Ridley was nominated one of the commissioners for examining Gardiner, bishop of Winchester, and concurred in his deprivation. In 1550 bishop Ridley visited his diocese, and he directed that the altars should thenceforth be taken down in the churches, and tables substituted in their room, for the celebration of the Lord's supper; to take away the false persuasion which the people had, of sacrifices to be offered upon altars. In 1551 the sweating sickness prevailed in London, and in the space of a few days carried off eight or nine hundred persons; but in the midst of the alarm which this necessarily occasioned, Ridley administered in the duties of his office, trusting himself entirely to the good providence of God for safety, in the danger to which he was every moment exposed; and he endeavoured, with all the zeal of an exemplary spiritual pastor, to improve the public calamity to the reformation of the manners of the people. To promote more generally a reformation in the

doctrine of the church, the council, this year, appointed Cranmer and Ridley to prepare a book of articles of faith. With this view they drew up forty-two articles, and sent copies of them to the other bishops and learned divines, for their corrections and amendments; after which the archbishop reviewed them a second time, and then presented them to the council, where they received the royal sanction, and were published by the king's authority, as an act of the supremacy. In the year 1552 he paid a visit to the princess Mary, and offered to preach before her; but she refused to hear him herself, or permit her servants to attend to his doctrine; telling him, that, in her father's days, he would not have dared to have avouched that for God's word that he then did. Mary never forgot nor forgave this interference on the part of the prelate, which, notwithstanding the remarks of most of Ridley's biographers, appears to us to have been uncalled for, if it were not even an act of rudeness not easily justified.

When the parliament assembled in 1553, the king, who was languishing under the decline which soon put an end to his life, ordered the two houses to attend him at Whitehall, where bishop Ridley preached before him, recommending with such energy the duties of beneficence and charity, that his majesty sent for him, to inquire how he could best put in practice the duties which he had so well and so strongly enforced; and the result of this sermon and conference was a determination in the king to found, or incorporate anew, and endow with ample revenues, those noble institutions, Christ's, Bartholomew's, Bridewell, and St. Thomas's hospitals.

Upon the death of Edward VI., Ridley was earnest in attempting to set lady Jane Grey on the throne; but when the design had miscarried, he went to Mary to do her homage, and submit himself to her clemency. His reception was such as he might have expected: he was immediately committed to the Tower, where, however, he was treated with much less rigour than Cranmer and Latimer, who were likewise prisoners in the same fortrefs. Ridley, it has been thought, might have recovered the queen's favour, if he would have brought the weight of his learning and authority to countenance her proceedings in religion. He was, however, too honest to act against his conviction; and he was, after eight months' imprisonment in the Tower, conveyed from thence to Oxford, where he was, on the 11th of October 1555, condemned to death for heresy. During the fortnight between his condemnation and execution, the priests tried all their means of persuasion to gain him over to their cause. He was deaf to their remonstrances, and was not to be shaken in the principles which he had adopted.

The 15th of October being the day appointed by the court for his execution, he met the trial with calmness and fortitude. He called it his marriage-day, and supped on the preceding evening with the utmost cheerfulness, having invited some friends on the occasion. When they rose to depart, one of them offered to sit up with him through the night, which he would not permit, saying, he meant to go to bed, and, by God's will, to sleep as quietly that night as he ever had done in his life. On the following morning, having dressed himself in his episcopal habit, he walked to the place of execution, between the mayor and one of the aldermen of Oxford; and seeing Latimer approach, from whom he had been separated since their condemnation, he ran to meet him, and with a cheerful countenance embraced him, and exclaimed, "Be of good heart, brother, for God will either assuage the fury of the flames, or else give us strength to endure them." Then walking to the stake, he

kneeled down, kissed it, and prayed with great fervour. A sermon was now preached, at the conclusion of which he was asked to recant; but he refused, and with a steadfast voice cried out, "May God's will be done." He was then stripped to his shirt, and fastened by an iron chain to the same stake with bishop Latimer. Every thing being ready, a kindled faggot was laid at Ridley's feet, who, when he saw the fire flaming up towards him, with a loud voice commended his soul to God. Latimer's sufferings were soon at an end, but Ridley endured the agonies of dying a much longer time, till they were terminated by the explosion of a bag of gunpowder, which had been suspended from his neck: after this he discovered no signs of life. Such was the end of bishop Ridley, who was unquestionably one of the most eminent instruments in promoting the cause of the reformation. In private life he was a pattern of all the virtues. His temper was excellent; his manners very affable and agreeable; and of the benevolence of his heart he gave abundant proofs, in his extraordinary liberality to the poor. He was unquestionably a man of great learning, and was author of a number of works. Many of his letters have been published by Fox, in his "Acts and Monuments;" and may likewise be seen in Glotter's *Life of Bishop Ridley*, to which, to Wood's *Athen.*, and Neal's *Hist. of the Puritans*, our readers are referred.

RIDLEY, *Sir THOMAS*, a learned civilian, of the same family as the preceding, was born at Ely, and educated first at Eton, and then at King's-college, Cambridge. He afterwards became a master in chancery, and vicar-general to the archbishop of Canterbury. He died in 1628, and was author of "A View of Civil and Ecclesiastical Law."

RIDLEY, GLOSTER, of the same family with the preceding, was born in 1702, on board the Gloucester East Indiaman, whence he derived his name. He was educated in school-learning at Winchester; from which place he was removed to New-college, Oxford, where he laid the foundation for those acquirements, by which he was afterwards distinguished as a poet, historian, and divine. He obtained some preferment in the church; and in 1740 and 1742 he preached eight sermons at lady Moyer's lecture, which were published. In 1763 he published the "Life of Bishop Ridley," to which we have referred; and shortly after, "A Review of Philips's Life of Cardinal Pole." In reward for his labours in this controversy, and in another which Mr. Archdeacon Blackburn's Confessional produced, he was presented by Secker to a golden prebend at Salisbury. He died in 1774, leaving a widow and four daughters, one of whom, Mrs. Evans, published several novels. In the latter part of his life he lost two sons, young men of considerable talents. The elder, James, was author of "The Tales of the Genii;" a humorous paper, called "The Schemer," afterwards collected into a volume; "The History of James Lovegrove," and several other literary pieces. Two poems by Dr. Ridley, one styled "Jovi Eleutherio, or an Offering to Liberty;" and the other entitled "Psyche," were printed in Doddsley's Collection. "Melampus," the sequel of the latter, was printed by subscription. His transcript of the Syriac Gospels was published with a Latin translation, by professor White, in 2 vols. 4to. Gen. Biog.

RIDLEY, in *Geography*, a township of America, in Delaware county, Pennsylvania, containing 991 inhabitants.

RIDOLLY, a town of Hindoostan, in the subah of Agra; 35 miles S. of Agra.

RIDZIN. See REUSSIN.

RIE, in *Rural Economy*, a provincial term, applied to the operation of turning grain in a sieve, so as to bring the

capas into an eddy at the top. It is performed by a particular kind of circular motion.

RIEBACH, in *Geography*, a town of Germany, in the county of Hohenloe; 7 miles S.S.E. of Weichenheim.

RIEBECK-CASTEEL, or the castle of Van Riebeck, one of the divisions in the district of Stellenbosch and Drakenstein, in the Cape district, Southern Africa, which may be considered as a prolongation of the *Paardeberg* (which see), terminating to the northward in a high rocky summit. It took its name from the founder of the colony having travelled to this distance from the Cape, which is about 60 miles, and which, in that early period of the settlement, was as far as it was considered safe to proceed, on account of the numerous natives, whose race has now almost disappeared from the face of the earth. The produce is the same as that of Paardeberg, in both which there are as many corn-farms as freehold estates.

RIEBEN, a town of Brandenburg, in the Middle Mark; 3 miles S. of Belitz.

RIECHENAU, a town of the country of the Grisons; 9 miles S.S.W. of Coire.

RIED, a town of Bavaria; 18 miles S. of Passau.—Also, a town of Bavaria, in the principality of Aichstatt; 4 miles S.E. of Harrieden.

RIEDEN, a town of Germany, belonging to Anspach, insulated in the principality of Culmbach; 22 miles N. of Anspach.—Also, a town of Bavaria, in the Upper Palatinate; 9 miles S. of Amberg.

RIEDENBURG, a town of the bishopric of Passau, on the Inn; 12 miles S.S.W. of Passau.—Also, a town of Bavaria, on the Altmuhl; 17 miles N.E. of Ingolstadt.

RIEDLIN, *Virus*, in *Biography*, a distinguished German physician, was born at Ulm in March, 1656, where many of his ancestors had practised the same profession with considerable repute. He obtained his early education principally at his native city, and terminated his studies by going to Tuningen in 1674, where he made great acquisition, during a residence of two years, and afterwards into Italy; and he graduated at Padua, about the end of the year 1676. He wished to have resided longer at this distinguished university; but his father having died in his boyhood, he was unable to procure the necessary means, and therefore he returned to Ulm in the following year. In 1679 he was elected a member of the college of physicians at Augsburg, where he settled, and obtained a considerable share of practice among the first people; but on the pressing solicitations of his countrymen, he returned to Ulm in 1704, and remained there, in the enjoyment of extensive reputation, till his death, which took place in 1724. His principal work is entitled "Linæ Medicæ, continentes Observaciones, Historias, Experimenta, Cauteles, &c. à Menſe Januario 1695 ad Menſem Junium 1700," in ten small volumes. It is a sort of journal, in which he not only recorded his own observations, but those of others. It does not, however, commend itself by much originality or good method. Eloy *Diſc. Hiſt.*

RIEDLINGEN, in *Geography*, a town of Wurtemberg; 27 miles S.W. of Ulm. N. lat. 48° 11'. E. long. 9° 30'.

RIEFF. See RIVA.

RIEGEL, HENRY JOSEPH, in *Biography*, a musician born at Wertheim, in Franconia, in 1741. M. Laborde does him the honour to call him a French composer. He studied music under Jomelli, at Stutgard, and was recommended by Richter to complete the musical education of a young lady of rank in France; which having finished, he established himself at Paris in 1765. His passion for the harpsichord

harpsichord confined his studies chiefly to that instrument for a considerable time; but after having acquired a distinguished reputation for his execution, he attended scholars, and applied to composition. Besides many quartets, concertos, sonatas, duos, &c. he composed symphonies à grand orchestra, which had considerable success at the concert of amateurs. He gained reputation by a French oratorio, "The Flight from Egypt," the first work of that kind that was executed at the Concert Spirituel, where it was well received for four successive years. A second oratorio, "The Taking of Jericho," had likewise merited applause.

His comic opera, "The Cobbler and Financier," was at first represented at court, but afterwards well received in the capital, at the Italian theatre, though not performed by the best actors.

What characterizes his compositions is the great purity of his harmony. His effects are ingenious: in his capital pieces of symphonic composition, there is always a natural and regular melody. This composer, passionate for his art, enjoyed, free from envy, the talents of others. An enemy to cabal, he was exclusively attached to no kind of style; but enjoying whatever was good in all styles, (French, Italian, German,) he was one of the few foreigners who did the most honour to the profession in France. Laborde.

RIEHEN, in *Geography*, a town of Switzerland, in the bishopric of Bâle, and principal place of a bailiwick; 3 miles E. of Bâle.

RIELVES, a town of Spain, in New Castile; 11 miles N.W. of Toledo.

RIEMLING, in *Ichthyology*, a name given by several to the small fresh-water fish, called by the Latins *poxinus*, and vulgarly the *pink*.

RIENECK, in *Geography*, a town and citadel of Germany, and capital of a county of the same name, on the Sinn; 36 miles E. of Frankfort on the Maine. N. lat. 50° 11'. E. long. 9° 47'.

RIENS ARREAR, in *Law*, a kind of plea used to an action of debt upon arrears of accounts; by which the defendant alleges, that there is nothing in arrear.

RIENS *passé par le fait*, nothing passes by the deed, is the form of an exception taken in some cases to an action.

RIENS *par descent*, nothing by descent, is the plea of an heir, when sued for his ancestor's debt, though he had no lands from it by descent, nor has assets in hand.

RIENTZ, in *Geography*, a river of the county of Tyrol, which joins the Eysach, at Brixen.

RIENZI, in *Biography*. See GABRINI.

RIER, or REER-COUNTY, *Retro-comitatus*, in *Law*, is used in the statute of Westm. 2. c. 39. 2 Edw. III. cap. 5. and in our law-books, in opposition to *open county*.

This appears to be some public place, which the sheriff appoints for the receipt of the king's money, after the end of the county-court. Fleta says it is *dies crastinus post comitatum*.

RIERSDORFF, in *Geography*, a town of Austria; 3 miles W. of Mauttern.

RIESENBURG, a town of Prussia, in the province of Oberland; 18 miles S.W. of Königsberg. N. lat. 53° 43'. E. long. 19° 24'.

RIESENKOPPE, or SCHNEE, a mountain of Silesia, and one of the most elevated in Europe, in the principality of Jauer.

RIESSA, a town of Saxony, in the margraviate of Meissen, on the Elbe; 12 miles N.W. of Meissen. N. lat. 51° 18'. E. long. 13° 15'.

RIETBERG, a town of Germany, and capital of a county of the same name, on the Embs, which county is

about 18 miles long and 6 broad; 12 miles W.N.W. of Paderborn. N. lat. 51° 55'. E. long. 18° 32'.

RIETI, a town of Italy, in the duchy of Spoleto, the see of a bishop; containing, besides the cathedral, three collegiate and six parish churches, and 12 convents. In the year 1785, it was much damaged by an earthquake; 25 miles E.S.E. of Spoleto. N. lat. 42° 44'. E. long. 12° 56'.

RIEV VOLODIMEROV, a town of Russia, in the government of Tver; 64 miles S.W. of Tver. N. lat. 56° 5'. E. long. 34° 44'.

RIEUMS, a town of France, in the department of the Upper Garonne, and chief place of a canton, in the district of Murat; 9 miles S.W. of Murat. The place contains 1425, and the canton 6316 inhabitants, on a territory of 200 kilometres, in 15 communes.

RIEUPEIROUX, a town of France, in the department of the Aveyron, and chief place of a canton, in the district of Villefranche; 15 miles W. of Rodes. The place contains 1752, and the canton 6299 inhabitants, on a territory of 182½ kilometres, in 13 communes.

RIEUX, a town of France, and principal place of a district, in the department of the Upper Garonne; and before the revolution, the see of a bishop; 24 miles S. of Toulouse. N. lat. 43° 15'. E. long. 1° 17'.—Also, a town of France, in the department of the Morbihan; 10 miles S.E. of Rochefort.—Also, a town in the department of the Ille and Vilaine, on the Vilaine; 6 miles S. of Redon.—Also, a town in the department of the Aube; 10 miles E. of Carcassonne.

RIEZ, an old, populous town of France, formerly Civitas Reicensium, a bishop's see, and the seat of a council in 439, situated on a plain between the Aife and Verdun, in the department of the Lower Alps, and chief place of a canton, in the district of Digne; 18 miles S. of Digne. The place contains 2784, and the canton 9963 inhabitants, on a territory of 330 kilometres, in 14 communes. Its environs abound in wine and fruits.

RIEZE, a river of France, which runs into the Garonne, near Saverdun.

RIF, one of the largest provinces of the empire of Morocco, situate in that chain of mountains which forms a part of the Lesser Atlas. This province, the soil of which is stony, is bounded by that of Garet to the east, the Mediterranean to the north, on the coast of which is the ancient city of Gomera, and also Melilla and Veles de Pegnon, belonging to Spain; by the province of Garb to the west, and to the south by those of Shaus or Chaus, and Fez.

RIF. See BAHIRA.

RIF-DYKE, one of the smaller Orkney islands, east of North Ronaldsha. N. lat. 59° 13'. W. long. 2° 17'.

RIFENBACH, a river of Germany, which runs into the Inn, 2 miles N. of Kuffstein.

RIFFREDO, a town of Etruria; 20 miles N.N.E. of Florence.

RIFLE GUNS, in the *Military Art*, are those whose barrels, instead of being smooth on the inside, like our common pieces, are formed with a number of spiral channels, resembling female screws; except only that the threads or rifles are less deflected, making only one turn, or a little more, in the whole length of the piece. This construction of the barrel is employed for correcting the irregularity in the flight of balls from smooth barrels, of which we have mentioned several instances under our articles GUNNERY and PROJECTILES. It has, for instance, been found, from the experiments of Mr. Robins, that notwithstanding the piece was firmly fixed, and fired with the same weight of

## RIFLE GUNS.

powder, sometimes the ball was deflected to the right, sometimes to the left; sometimes above, and at others below, the true line of direction. It has also been observed, that the degree of deflection increases in a much greater proportion than the distance of the object fired at: thus, at double the distance, the deflection of the ball from the line in which the piece is pointed is considerably more than double, and at treble the distance more than treble, what it was at first. Mr. Robins secured a musket barrel upon a block of wood, and firing it with a ball at a board of a foot square, at 60 yards distance, found that it missed the board only once in 16 successive discharges; yet when fired with a smaller charge, at the distance of 760 yards, the ball was thrown sometimes 100 yards to the right or left of the line in which it was pointed. The direction upwards and downwards was also found equally uncertain; the ball, in some discharges, having struck the ground 200 yards nearer the piece than it did at others.

It is not difficult to account for these irregularities: they doubtless proceed from the impossibility of fitting a ball so accurately to any plain piece, but that it will rub more against one side of the barrel than another, in its passage through it. Whatever side, therefore, of the muzzle the ball is left in contact with, on quitting the piece, it will acquire a whirling motion towards that side, and will be found to bend the line of its flight in the same direction, whether it be upwards or downwards, to the right or left; or obliquely, partaking in some degree of both; and after quitting the barrel, this deflection, which, though in the first instance it is but trifling and inconsiderable, is still farther increased by the resistance of the air; this being greatest on that side where the whirling motion conspires with the progressive one, and least on that side where it is opposed to it. Thus, if the ball, in its passage out, rubs against the left side of the barrel, it will whirl towards that side; and as the right side of the ball will, therefore, turn up against the air during its flight, the resistance of the air will become greatest on the right side, and the ball be forced away to the left, which was the direction it whirled in. If the axis, about which the rotatory motion of the ball is made, preserved its position during the whole flight, the deflection would be in the same direction from one end of the track to the other; though it is obvious, that the quantity of this deflection would still not be proportional to the distance: for if all resistance of the ball were to cease at any part of its flight, still the ball would necessarily pursue the line in which it then moved, and the deflection be double at a double distance, treble at a treble distance, and so on. But as this resistance does not cease, but continue to act upon the ball throughout its whole flight, (though less in the latter part of it than at the commencement, in consequence of the decrease of velocity,) it is obvious that the deflection of the ball will be accelerated at every instant, and consequently increase in a greater proportion than the distance; as we have seen it has been found to do, from the experiments above alluded to. It happens, however, from various accidental circumstances, that the axis of the ball's rotation frequently changes its position several times during the flight; so that the ball, instead of bending its course uniformly in the same direction, often describes a track variously contorted. So great, however, is the tendency of the ball to deflect itself against the side it rubs against, that it has been said, though we never saw the experiments authenticated, that a ball, when fired out of a barrel bent towards the left hand, (and which will, therefore, be thrown from the piece in the direction of the bend,) yet as the ball, in this case, will be forced to rub against the right side of

the muzzle, and thus turn its left side up against the air, so it will be found to alter its course during the flight, and bend towards the right hand, so as to fall a considerable way to the right hand of the line in which the piece was pointed.

It will readily appear, therefore, from what has been stated, that these variations will be more frequent and considerable when the ball runs very loose in the piece; or when, from any roughness on its surface, or on the middle of the barrel, a considerable degree of friction takes place between them. With a view to prevent friction, it has been proposed to grease the ball; but this we should imagine would be of very little service. All that can be done in a plain barrel is to have the balls cast very solid and true, and afterwards milled in the same manner as is now practised upon shot: the barrel also should be very smooth on the inside, and the ball fit it very accurately, so as to leave scarcely any windage: yet, with all these precautions, it is very difficult, we may say impossible, to prevent it entirely; for gravity will constantly act, and friction on the under side will naturally be occasioned by the weight of the ball. In fact, when we consider the causes of the aberration in the flight of balls, it will be pretty evident that the only means of correcting it is by preventing the ball from rubbing more against one side of the barrel than another in passing through it; and by giving to the bullet a motion which will counteract every accidental one, and preserve its direction, by making the resistance of the air upon the fore part continue the same during its whole flight; that is, by giving it a rotatory motion perpendicular to the line of direction. The contrivance for this purpose is called rifling, and consists of forming upon the inside of the barrels a number of threads and furrows, either in a straight or spiral direction, into which the ball is moulded, whereby any rolling motion along the sides of the barrel is effectually prevented.

The numbers of these threads in a gun are different, according to the fancy of the workman and the size of the barrel; and, in like manner, the depth to which these channels or rifles are cut down, is not regulated by any invariable rule; but differs according to the country where the work is performed, or the caprice of the artificer. There are also different methods of charging pieces of this kind, but the usual one is as follows: after the powder is put in, a leaden bullet, somewhat larger than the bore of the gun, is taken, and having greased it well, it is laid on the mouth of the piece, and rammed down with an iron rammer, hollow at the end; the softness of the lead giving way to the violence with which the bullet is impelled, that zone of the bullet which is contiguous to the piece, varies its circular form, and acquires the shape of the inside of the barrel, so that it becomes the part of a male screw, exactly fitting the indents of the rifle. And hence it happens that, when the piece is fired, the indented zone of the bullet follows the sweep of the rifles, and thereby, besides its progressive motion, acquires a circular one round the axis of the barrel, which motion will be continued to the bullet after its separation from the piece; by which means a bullet discharged from a rifled barrel is constantly made to whirl round an axis, which is coincident with the line of its flight. And hence it follows, that the resistance on the foremost surface of the bullet is equally distributed round the pole of its circular motion, and acts with an equal effort on every side of the line of direction, so that this resistance can produce no deviation from that line: and if, by the casual irregularity of the foremost surface of the bullet, or by any other accident, the resistance should be stronger on one side of the

## RIFLE GUNS.

the pole of the circular motion than on the other; yet, as the place where this greater resistance acts must perpetually shift its position round the line, in which the bullet flies, the deflection, which this inequality would occasion, if it acted constantly with the same given tendency, is now continually rectified by the various and contrary tendencies of that disturbing force, during the course of one revolution; so that the ball will always go right forwards, and thus that deflection or deviation, already taken notice of under the article PROJECTILE, and in the preceding part of this article, will be prevented. This may be explained by the motion of an arrow; for if an arrow that is not feathered be shot from a bow, its motion will be very irregular; but when the feathers of the arrow are properly arranged in a spiral form, so as to make the arrow spin round its axis, it will always fly straight forward. Upon the same principle, every school-boy finds himself under the necessity of making his shuttle-cock spin, before he can depend upon the truth of its flight. Mr. Robins observes, that the actual motions of bullets discharged from rifled pieces correspond very well with these speculations. Although the use of pieces of this kind had long prevailed in Europe, particularly in Germany and Switzerland, the advantages resulting from them have been very imperfectly understood, and, as Mr. Robins observes, unaccountably misrepresented. The three following reasons have been constantly alleged in favour of this construction: either that the inflammation of the powder was greater by the resistance which the bullet thus forced into the barrel gave it, and that by it the bullet received a much greater impulsion than it would have done from the same quantity of powder in a common piece, or that the bullet, by the compounding of its circular and revolving motion, did, as it were, bore the air, and thereby flew to a much greater distance, than it would otherwise have done; or that, by the same boring motion, it made its way much easier through all solid substances, and penetrated much deeper into them, than if discharged in the common manner. But the ingenious writer just mentioned, satisfied himself by numerous experiments made with rifled barrels of various sizes, that none of these reasons hold true in the use of such pieces; but that the advantage of their construction results from its preventing the deflection of the ball, as we have above represented it. And that it produced this effect he found by observing, that the same hemisphere of the bullet which lies foremost in the piece, continued foremost during the whole course of its flight.

In Germany and Switzerland, an improvement is made in the method, already recited, of charging these pieces; especially those of the larger sort, which are used for shooting at great distances. This is done by cutting a piece of very thin leather, or of thin suttian, in a circular shape, somewhat larger than the bore of the barrel. This circular piece being greased on one side is laid upon the muzzle with its greasy parts downwards, and the bullet being placed upon it, is then forced down the barrel with it; by which means the leather or suttian incloses the lower half of the bullet, and by its interposition between the bullet and the rifles, prevents the lead from being cut by them. But in those barrels where this method is practised, the rifles are generally shallow, and the bullet ought not to be too large. The rifle-barrels, which have been made in England, where they are not very common, are contrived to be charged at the breech, the piece being, for this purpose, made larger there than in any other part. The powder and bullet are put in through the side of the barrel by an opening, which, when the piece is loaded, is filled up

with a screw. By this means, when the piece is fired, the bullet is forced through the rifles, and acquires the same spiral motion as in the former kind of pieces; other barrels unfcrew at the breech, for the convenience of charging them. With regard to the defects of these rifled pieces, Mr. Robins observes, that if either the angle of elevation, or the curvature of the bullet's track through the air be great, the inclination of the axis round which it whirls will cause irregularities, which will often produce considerable deflections. Accordingly he proposes to make use of bullets of an egg-like form, instead of spherical ones, and to fire them with their broad ends foremost, that thus their longer axes may be always carried, by their centres of gravity, into the lines of their flight. Upon the whole, he concludes, that whatever tends to diminish the friction of these pieces, tends, at the same time, to render them more complete; and consequently the less the rifles are indented, the better they are, provided that they are just sufficient to keep the bullet from turning round in the piece. Besides, the bullet ought to be no larger than to be just pressed by the rifles, for the easier the bullet moves in the piece, supposing it not to shift its position, the more violent and accurate its flight will be. And to render them in this respect still more complete, the sweep of the rifles should be in each part exactly parallel to each other: for then, after the bullet is once put in motion, it will slide out of the barrel without any shake, and with a much smaller degree of friction than if the threads of the rifles have not all of them the same degree of incurvation. The foreigners are so exact in this respect, that they try their pieces, with a view to this particular, in the following manner: they first pour melted lead into them, and letting it cool, they procure a leaden cylinder of perhaps two or three diameters in length, exactly fitted to one part of the inside of the piece; then if this leaden cylinder, being gently pushed by the rammer, will pass from one end of the barrel to the other, without any sensible strain or effort, they pronounce the piece perfect; but if it any where sticks or moves hard they esteem it defective.

We have stated that some rifle-pieces are charged at the breech; these, however, are necessarily much dearer than the others, and excepting the expedition in charging them, are really inferior to those in which the ball is introduced at the muzzle, on which account they are not much employed at present, at least not in this country. The want of expedition in the charging pieces of this kind is, however, a very serious defect, to remedy which, it has been proposed to have the balls cast with projections upon them, in the same manner as described in the following article on *RIFLE Ordnance*. This may be done with great ease and accuracy, by making corresponding hollows round the zone of the bullet-mould; by this means the balls may be fitted so accurately to the rifles, as to leave scarcely any windage; while the friction will be less than it is either when the ball is put in at the breech, or forced in at the muzzle.

In treating of the causes of aberration in the flight of balls, we have supposed the air to be perfectly at rest; but it is evident that the force of the wind will affect balls considerably, whether they are fired from a plain or a rifle barrel; this effect, however, will be much less in the latter than in the former; but in neither case is it possible either to avoid it entirely, or to estimate the quantity of aberration that it may, under different circumstances, occasion.

Pieces intended for shooting with ball, whether they be plain or rifled, ought to be of much more equal thickness

nefs from the breech to the muzzle, than thofe that are intended for fhoot only. In every barrel there is an undulating vibration communicated to the metal by the explosion. This is moft remarkable in a thin barrel, and when the charge is great, and in an equal degree, whether the piece be rifle or plain, and therefore ought to be equally attended to by gunfmiths in both cafes. For more on the fubject of rifle mufket barrels, fee Robins' Tracts, vol. i. p. 328, &c.; fee alfo Nicholfon's Philofophical Journal, vol. i. p. 382; and for rifle ordnance, fee the Memoir of the National Inftitute mentioned in the following article.

**RIFLE Ordnance.** After the important advantages attending rifled barrel mufkets were well underftood, the idea naturally occurred of carrying the fame improvements into cannons and field-pieces, and many experiments have been made with a view of contructing thefe on fimilar principles to the mufket. The firft attempt of this kind was made by Dr. Lind, and Capt. Alexander Blair, of the 69th regiment, in 1774. The pieces are of caft iron, and are not bored like the common cannon, but have the rifles moulded on their core, after which they are cleaned out, and furnifhed with the proper inftruments.

Guns of this defcription, which are intended for the field, ought never to be made to carry a ball of above one or two pounds weight at moft; a leaden bullet of that weight being fufficient to deftroy either man or horfe. A pound gun of this defcription, of good metal, need not weigh above an hundred weight, and its carriage about another hundred, and may therefore be eafily tranfported from place to place by a few men, and a couple of good horfes may tranfport fix of thefe guns and their carriages, if put into a cart. But for other purpofes, in which a greater momentum is neceffary, there is nothing to prevent them being made of the ufual calibre.

The following are the dimenfions that have been recommended for thefe kinds of cannon. The length of the gun being divided into feven equal parts, the length of the firft reinforce is two of thefe parts; the fecond reinforce  $1\frac{1}{2}$  of the diameter of the calibre; the chafe  $3\frac{1}{4}$  diameter of the calibre. The diftance of the hind part of the bafe ring to the beginning of the bore is  $1\frac{1}{4}$  calibre. The trunnions are each one calibre in length, and the fame in breadth; their centres are placed  $\frac{2}{3}$ ths of the length of the gun from the hind part of the bafe ring, in fuch a manner, that the axis of the trunnions pafs through the centre line of the bore, which prevents the gun from kicking, and breaking its carriage. The length of the eafcable is  $1\frac{1}{6}$  of a calibre.

The calibre of the gun being divided into 16 equal parts; then

The thicknefs of metal from the bafe ring to the bore, is	18.5
At the end of the firft reinforce	17
At the fame place for the beginning of the fecond reinforce	17
At the end of the fecond reinforce	15
At the fame place for the beginning of the chafe	13.75
At the end of the chafe, or muzzle, the mouldings excluded	9
At the fwelling of the muzzle	12
At the muzzle fillet	9.5
At the extreme moulding	8

The vent fhould be placed about half an inch from the bottom of the chamber or bore, that the cartridge may be pricked, left fome of the bottom of the cartridges fhould be left when the gun is fponged, which might retard the firing till the ball be again drawn, which is very difficult in pieces of this kind.

The rifles in this gun make one fpiral turn in the length of the bore, but go no nearer to the breech, in their full fize, than two calibres, and terminate in a gentle flope in half a calibre more, fo as not to prevent the cartridge, with the powder, from being eafily fent home to the bottom of the gun, which would otherwife constantly happen with the flannel cartridges, and even fometimes with paper ones, if not made to enter very loofely. The fhape of the rifles is femicircular, their breadth being equal to the diameter, which is  $\frac{1}{4}$ ths of the calibre, and their depth  $\frac{1}{6}$ ths of a calibre. The bullets are of lead, having fix knobs caft on them, to fit the rifles of the gun; and being thus made of foft metal, they do not injure the rifles.

Rifle ordnance, however, of any calibre, might be made to carry iron fhoot for battering, or for other purpofes; provided holes, that are a little wider at their bottoms than at their upper parts, be caft in a zone round the ball, for receiving afterwards leaden knobs to fit the rifles of the cannon; by which means the iron fhoot will have its intended line of direktion preferved, without injuring the rifles more than if the whole ball was of lead, the rotatory motion round its axis, or the line of its direktion, which corrects the aberration, being communicated to it by the leaden knobs following the fpiral turn of the rifles in their progrefs out of the gun. It is particularly to be obferved, that the balls muft be made to go eafily down into the piece, fo that the cartridge with the powder, and the bullet, may be both fent home together with a fingle push of the hand, without any wadding above either the powder or the ball, by which means the gun is quickly loaded, and the ball flies farther than when it is forcibly driven into the gun, as was found from many experiments. The only reafon why, in common rifle mufkets, the bullets are forcibly rammed in, is, that the zone of the ball which is contiguous to the infide of the bore, may have the figure of the rifles impreffed upon it, in fuch a manner, as to become part of a male fcrew, exactly fitting the indents of the rifle, which is not at all neceffary in the prefent cafe, the figure of the rifles being, in the firft intance, caft upon the ball. Thefe knobs retard the flight of the ball in fome degree, but this fmall difadvantage is fully counterbalanced by the eafe with which the gun is loaded, its fervice being nearly as quick as that of a common field-piece, and the retardation and quantity of the whirling motion which is communicated to the bullet being constantly the fame, it will not in the leaft affect the experiments

ments made with them, in order to determine the resistance of the air.

The French, in the course of the late war, have made experiments on rifle ordnance of a different kind to that above explained; in which, in fact, the gun is of the usual form, the principal difference being in the nature and form of the ball, which M. Guyton (who has given an account of these experiments in vol. vii. of the National Institute of France) calls *bullets a bague de plomb*, which in form are cylindrico-spherical, the cylindrical part being next the charge. A rim of lead is fixed round the centre of the ball, rather exceeding the bore of the gun, which is cut off by the edge of the muzzle, in introducing the ball into the piece, whereby all the advantages of the rifle are obtained, although the rotatory motion above described, and which is supposed to have so great an influence on the direction, has not place in the present instance. According to M. Guyton's report, the accuracy in the rectilinear motion of these balls exceeded any thing before known in artillery practice; besides, that although the weight of the bullet was nearly double that of a common shot of a piece of the same calibre, the range in very few instances fell short of the common range, and in some even considerably exceeded it. The difficulty and time requisite in loading a gun with a ball of this kind, however, are so great, as, in our opinion, to render it useless, although it seems to have been recommended for adoption, in a few particular situations, by a committee of French artillery officers. In the course of the memoir in which the above experiments are detailed, M. Guyton mentions another kind of rifle cannon, invented by an Italian officer, which was found remarkably correct in projecting the ball in a right line. The bore of this gun is slightly conical, being greatest at the breech, where the piece is loaded by unscrewing the breech, as in some rifle muskets and pistols: the ball is of lead, which must necessarily, from the construction of the gun, change its form in passing through the bore. But this, as well as the one above-mentioned, seem to require too much time in loading to be ever adopted as regular pieces of ordnance.

**RIFTS**, in *Farriery*, are small cracks, clefts, chaps, or any other similar fissures or openings in the hoofs of horses' feet. See those heads.

**RIG**. See **RIDLING**.

**RIG**, in *Rural Economy*, a male sheep, with none, or one teltle only in the ferotum.

**RIGA**, in *Geography*, a sea-port town of Russia, formerly the capital of Livonia, now of the government of its own name, is situated in the gulf of Riga, and the see of an archbishop. This town derives its consequence from its situation on the Duna, which, being navigable from the frontiers of the government of Polotsk, brings the productions of the north-eastern parts of Poland and the western provinces of Russia, and has depth enough to receive, close to its walls, ships of burden, which sail to and from the Baltic. Next to St. Peterburg, it is the most commercial town in the Russian empire. The trade is chiefly carried on by foreign merchants, who reside in the town. Those of the English factory possess the greatest share of the commerce, and live in an hospitable, splendid manner. The principal exports are corn, hemp, flax, iron, timber, masts, leather, tallow; and the imports are salt, cloth, silks, wine, grocery, potash, and salted herrings. The malt trade is peculiarly beneficial to the town; the burghers of Riga send persons, who are called mast-cutters, into the Russian provinces, to mark the trees, which are purchased standing. They grow mostly on the districts which border

the Dnieper, are sent up that river to a landing-place, transported 30 versts to the Duna, are then formed into floats of from 50 to 200 pieces, and descend the stream to Riga. The tree which produces the largest masts is the Scotch fir. Those pieces which are from 18 to 25 inches in diameter, are called masts; under those dimensions, spars, or, in England, Norway masts; because Norway exports no trees more than 18 inches in diameter. The English merchants, who contract with government, buy the masts from the burghers of Riga, which are skilfully examined in order to ascertain their soundness, and are usually from 70 to 80 feet in length.

The hemp is brought from the Ukraine and Poland, and requires two years in its passage to Riga. The barks in which it is conveyed are from 250 to 300 tons burden, are covered with mats, sloping like a pent-house roof, and have a false bottom. They ascend the Dnieper and Duna; but on account of numerous shoals, can only pass the Duna in the spring, or about three weeks after the snow begins to melt, and if they miss that time, they are delayed till autumn. The hemp exported from Riga is generally more esteemed, and 30 *per cent.* dearer than that exported from Petersburg; the former comes from the Ukraine, the provinces of Mohile and Polotsk, and the neighbouring parts of Poland; the other from the governments of Tver and Novogorod. The Riga hemp is chiefly used for shrouds and stays of men of war, and procured by contract for the English admiralty and the East India company.

The inhabitants of Riga carry on also a considerable commerce in salt. They import it from Spain, and send it up the Duna, to supply the districts bordering on that river; and by land into Courland, and into the neighbouring provinces of Poland. This town, says Mr. Coxe, contains within the fortifications 9000 inhabitants, and in the suburbs 15,000, exclusive of a garrison of 1000 soldiers. According to Heyn, the town and suburbs contain 14,280 males, and 13,516 females.

Over the Duna at Riga is a floating wooden bridge, 40 feet in breadth, and 2000 in length. A row of piles extends from one shore to the other; each pile is from 25 to 40 feet long, according to the depth of the river, and appears about four feet above the level of the water. To these piles the pons of the bridge are loosely fastened, by means of iron chains fixed to the transverse beams. The bridge rises and falls with the river; and, under the wheels of heavy-laden carriages, plays as if actuated by a spring. This is the fashionable walk, and is an agreeable busy scene, when crowded with people, and lined on each side with ships taking in or unloading their cargoes. In the beginning of winter, when the frost sets in, the bridge is removed; the piles, remaining in the water, are forced up by the ice, and conveyed to land; and the whole is laid down again in the spring.

Riga was built in the year 1200, and soon after inclosed by a wall. At different periods it hath suffered much by fires and sieges. N. lat. 56° 55'. E. long. 23° 54'.

**RIGA**, Ital., a line of the staff, in *Musick*; and speaking of music in general, the whole five lines, or staff, are called *una riga*.

**RIGADON**, **RIGODON**, and *Rigaudon*, a gay and lively dance, written all these several ways. Some say it came from Provence; but Rousseau affirms, that he has been told by an old dancing-master, that it had its name from its inventor, Rigaud.

At the beginning of the last century, there were three dances which every eminent master taught, and every nobleman's

man's and gentleman's child learned, in the course of their education: these were the minuet, rigaudon, and l'ouvre, all natives of France, during the reign of Louis XIV.

The air to the rigaudon is always in jig time of  $\frac{3}{4}$ , beginning with an odd quaver. See DANCE, MINUET, and L'OUVRE.

RIGAL, in *Musical*. See RIGOLL.

RIGAUD, HYACINTH, in *Biography*, was born at Perpignan, in Languedoc, in 1663, and was the son of Matthias Rigaud, a painter of some note, from whom, of course, he received his initiation into the mysteries of his art. He had the misfortune to lose his instructor, when he was only eight years of age; and for a while, he was at the mercy of incapable masters. At length he became acquainted with a portrait-painter, of the name of Ranc, under whom he acquired considerable freedom of taste; and, after a few years, was enabled to produce works which rivalled those of his master, for truth, for liveliness, and expression.

He was impatiently desirous of visiting Italy, but was dissuaded from it by Le Brun, who advised him to continue at Paris, and study portraiture; by which he might assure himself of fortune and reputation: and his subsequent success proved the propriety and kindness of the advice. He soon distinguished himself by a richness and boldness of style, that induced the king of France, Louis XIV., to sit to him for his portrait; and in succession, he painted the princes of the blood, and prime nobility of the kingdom. Many foreign princes, nobles, and generals, also had their portraits from his hand; and he treated them with a splendour in composition, of which he is the inventor, and which unfortunately governed the French school of portrait-painters till the revolution. We say, unfortunately!—for though Rigaud managed it with great dexterity, yet not being founded in nature, it necessarily led to error. To produce superior grace, the actions of the figures are twisted, and too often distorted: they are engaged about trifles, with an air of immense importance; and the draperies arranged in flowing lines, which convey an idea of motion in substances which would require a gust of wind to move them, while the wearers are tranquilly seated in splendid apartments, and under complete shelter. He died in 1743, at the advanced age of 80.

RIGAULT, NICHOLAS, was born at Paris in 1577, and was educated among the Jesuits, who in vain attempted to induce him to enter into their society. As a literary character, he made himself known by a satirical work, entitled "Fusus Parasiticum," published in 1596; with which the celebrated de Thou was so much delighted, that he entrusted him with the education of his son. When the learned Casaubon, who had the care of the royal library, removed to England, Rigault succeeded him in that employment. His services were so well approved, that he was created attorney-general of the sovereign chamber of Nauci, counsellor to the parliament of Metz, and, finally, intendant of that province. He died at Toul in 1654, at the age of 77, with a character for generosity, modesty, and benevolence, that contributed as much to his reputation as his numerous writings. It was chiefly as an editor of Greek and Latin authors that he made himself known to the learned world. Of these were "Minutius Felix," 1643; "St. Cyprian," 1648; and "Tertullian," 1664; enriched with useful notes, corrections, and observations. He gave translations of the Greek writers, "Onofander," "Artemidorus," and others; and he edited, with notes, "Phædrus," "Martialis," "Rei Agrariæ Scriptores," &c. He also wrote and edited some works on juridical subjects;

and he was appointed, together with Peter Dupin, by the will of the president de Thou, to give a complete edition of his history, which appeared at Geneva in 1620.

RIGEL, in *Astronomy*. See REGEL.

RIGEL, or RIEGEL, ANTHONY, in *Biography*, a harp-fichord maker and composer. In 1780 he was at Spire, Manheim, and Paris, where he published pieces for the harp-fichord, with a violin accompaniment in duo, *a parte equali*; and afterwards capriccios for the harp-fichord. His style is slight, with little invention, but not vulgar.

RIGG, in *Agriculture*, a provincial word, used to signify the fame as ridge.

RIGGEN, in *Rural Economy*, the ridge of the roof of a building. See FARM-Building.

RIGGEN-Tree, the piece of timber laid along the ridge of a roof, to support the heads of the spars or rafters, which, in modern buildings, is found unnecessary.

RIGGIL. See RIG and RIDGIL.

RIGGING, a general name given to all the ropes employed to support the masts, and to extend or reduce the sails, or arrange them to the disposition of the wind.

The former, which are used to sustain the masts, remain usually in a fixed position, and are called *standing rigging*: such are the shrouds, stays, and backstays. (*Plate III. Rigging, fig. 1.*) The latter, whose office it is to manage the sails, by communicating with various blocks, &c. situated in different parts of the masts, yards, shrouds, &c. are comprehended in the general term of *running rigging*: such are the braces, sheets, haliards, clue-lines, brails, &c. *Plate III. fig. 2.*

The principal objects to be considered in rigging a ship appear to be strength, convenience, and simplicity; or the properties of affording sufficient security to the masts, yards, and sails; of arranging the whole in the most advantageous manner, to succour the masts, and facilitate the management of the sails; avoiding perplexity, and rejecting whatever is superfluous and unnecessary. The perfection of this art, then, consists in retaining all these qualities, and in preserving a judicious medium between them.

Rigging is in part prepared on shore, in a rigging-house, which has the following conveniences, &c.; *viz.* at the upper end is a windlass; and at certain distances down the middle are two rows of large strong posts, for stretching ropes, and laying on service; and on each side of the house are births for the men to stow blocks, and prepare small rigging on.

There is much subordinate knowledge necessary, before a person can either prepare rigging in the house, or fit it on board the ship. This consists of *knocking*; as the over-hand knot (*Plate I. fig. 1.*); reef-knot, *fig. 2*; bowline-knot, *fig. 3*; wall-knot, *figs. 4 and 5*; double wall-knot crowned, *fig. 6*; buoy-rope-knot, *fig. 7*; stopper-knot, *fig. 8*; diamond-knot, single, *fig. 9*; diamond-knot, double, *fig. 10*; shroud-knot, opened for knocking, *fig. 11*; as knotted, *fig. 12*; ends tapered and served, which completes it, *fig. 13*; tack-knot, *fig. 14*; sprit-sail sheet-knot, *fig. 15*.

*Hitches*.—Sheepshank, *fig. 16*; half-hitches, *fig. 17*; clove-hitch, *fig. 18*; rolling-hitch, *fig. 19*; midshipman's hitch, *fig. 20*; Blackwall-hitch, *fig. 21*; magnus-hitch, *fig. 22*; timber-hitch, *fig. 23*; racking-hitch, *fig. 24*.

*Bends*.—Sheet-bend, *fig. 26*; Carrick-bend, *fig. 27*; fisherman's bend, *fig. 30*; hawser-bend, *fig. 31*; temporary bend, *fig. 32*.

Gasket, *fig. 25*; outside-clinch, *fig. 28*; cat's-paw, *fig. 29*.

## RIGGING.

*Splices.*—Eye-splice, ends opened, *fig. 33*; finished, *fig. 34*; short-splice, ends opened and laid together, *fig. 35*; finished, *fig. 36*; long-splice, ends opened and laid for splicing, *fig. 37*; finished, *fig. 38*; cunt-splice, ends opened and laid for splicing, *fig. 39*; finished and served over the splice, *fig. 40*; cable-splice for drawing, ends opened, tapered, and pointed, *fig. 41*; tapered short-splice, *fig. 42*. This splice is served all over the splice.

*Hawser*, the ends opened, *fig. 43*; tapered and pointed, *fig. 44*; ditto with a becket, *fig. 45*.

*Worming*, *fig. 46*; *parling*, *fig. 47*; *serving*, *fig. 48*; *plattin*, *fig. 49*.

The ropes, &c. for the several parts of rigging are, in circumference and in length, according to the established dimensions for ships of every class, particularly in the navy.

There is no one undeviating mode which is pursued in the progressive rigging of ships. It is an operation which must at all times depend upon the time allotted for its performance, and the necessity of immediate fitting. The nature of it, however, is such, that all parts may be advancing at the same time, the lower masts and bowsprit being fixed.

*Fore, main, and mizen masts*, have girtline-blocks lashed round the mast-head, above the stop of the cap, one to hang on each side. The girtlines that reeve through them lead down upon deck, for hoisting the rigging, tops, &c. and the men employed to place the rigging over the mast-head.

*Pendants of tackles* are wormed, parcelled, and served with spun-yarn, in the way of the splice (which is to the size of the mast-head); they have large iron thimbles spliced into their lower ends; are then wormed, &c. as above, the whole length in the house; and are the first thing put over the mast-head, resting on the bolsters, they being first clothed with worn canvas several times doubled and tarred. Those over the mizen-mast are called burton-pendants, as 2, 3, *Plate III. fig. 1*.

*Shrouds.*—The cable is warped round two iron sids fixed in the floor, distant from each other the length of the first warp; that is, from the top of the bolster to the foremost dead-eye; one end of the cable is made fast to the lower sid, and the remainder passed round the upper sid; and so on alternately, one turn close to the back of another. The additional length, gained by the turns lying round each other, is sufficient for the lengthening of each pair of shrouds, as they rake aft. When the whole gang of shrouds is warped out, the bights at the lower end are cut through, in a straight direction, with the sids.

Brigs have four pair of shrouds forward, and the foremost shroud and pendant are in one. The upper bights are designed for the eyes, and the outer turns are called *swifsters*, and are left from four to five feet at each end longer than the shrouds, and have an eye spliced in them to the size of the mast-head.

The shrouds, when cut to their length, are stretched for worming by the windlafs and tackle, and then wormed with double spun-yarn one-fourth the length from the centre of the eye on each side: but the fore leg of the foremost pair is wormed all the whole length. Each length, after being wormed, is hove out, till each pair has acquired, by stretching, one and a half the length of the eye; and should remain on that stretch twenty-four hours, before the service is laid on.

The eyes of all shrouds are parcelled with worn canvas, well tarred, about one fathom and a half on each side of the middle for large ships, and proportionably for smaller; and then served with spun-yarn one-fourth of their length; each

turn of the serving is laid very close, and strained tight round, to prevent the water penetrating. The fore leg of the foremost pair of shrouds is served the whole length.

*Swifsters*, when stretched, have the length of the splice set off on each side of the middle, and likewise the length of the eye, or circumference of the mast-head. The latter is parcelled and served as above. They are then cut asunder in the middle, and spliced to the circumference of the mast-head; then got on the stretch, and served over the splice one-fourth of the length.

The bights of shrouds are seized together to the circumference of the mast-heads, 1, 2, (*Plate II. figs. 14 and 15.*); the seizing of the first shroud is put on below the bolster or trestle-trees, with seven under and six riding turns, and a double cross over all. The seizing of each shroud is to be laid its breadth below the next, and clear of each other, to prevent chafing.

Thus far the shrouds are prepared in the house: they are next hoisted over the mast-head. The first pair leads down on the starboard side forward; the next pair forward on the larboard side; then the second pair on the starboard, and the second on the larboard, and so on, till all are fixed. By this method, the yards are braced to a greater degree of obliquity, when close hauled; which could not be were the foremost shrouds last fitted on the mast-head.

*Swifsters* (which are the after shrouds) are swayed next over the mast-head above the shrouds, and are fixed on the starboard and larboard sides of the ship, to support the masts, and enable them to bear the strain of a heavy press of sail; as 4, 5, 6, *Plate III. fig. 1*.

*Stays* have an eye spliced in one end, 1, (*Plate II. fig. 16.*) sufficiently to receive itself through. Each stay is got on the stretch, and hove well out, as the shrouds were; then wormed with spun-yarn one-third the length; and then hove out, till the middle strand or heart is made to break in several places. The mouse, 2, (*Plate II. fig. 16.*) made with spun-yarn, &c. in the shape of a pear, is then raised on the stay, at one-third of its length, or by some at two sides of the mast-head, added to twice the length of the trestle-trees from the eye to the mouse. The warp of the mouse to be marline, and the pointing continued the circumference of the stay for the length of the tail. The collar, 3, the eye, 1, and one fathom below the mouse, 2, to be parcelled with worn canvas, well tarred, and served over with spun-yarn. (*Plate II. fig. 16.*) The stay is hoisted over the mast-head, and supports the mast, by extending from its upper end towards the fore part of the ship, and counteracts the strain of the shrouds which lead aft; and thus is the mast kept in a firm position fore, aft, and side-ways.

*Preventer-stay* is next hoisted over the mast-head, the same as the former.

*Collars.*—Fore-stay-collars are fitted to the circumference of the bowsprit, and spliced together at the ends; wormed, parcelled, and served the whole length; then doubled, and a heart seized in the bight. The splice is to lie on the back of the heart with *quarter-seizings*, a score being cut on each side of the heart, large enough to admit from nine to twelve turns of seizing; the seizing to be snaked on the back, to lie closely.

*Main-stay-collar*, 4, (*Plate II. fig. 16.*) is made by the rope-maker with an eye in one end: in the house it is wormed, parcelled, and served round the eye and the whole length.

The fore-stay, 7, (*Plate III. fig. 1.*) and main-stay, have a heart turned into the lower end with a throat-seizing, 5,

## RIGGING.

(*Plate II. fig. 16.*) and two round-seizings, 6 and 7, above, and the end of the stay capped with canvas, whipped and tarred, 8; then set up with its laniard, 9, (*Plate II. fig. 16.*) which is alternately reeved through the heart in the stay and the heart in the fore-stay-collar on the bowsprit. The laniard is set up with a luff-tackle, or luff upon luff, and the four first turns are flopt, and so on, till the laniard is expended: the end is then well flopt.

The fore-preventer-stay, 8, (*Plate III. fig. 1.*) sets up as the fore-stay.

The main-stay, 9, (*Plate III. fig. 1.*) sets up as the fore-stay. Its collar reeves from the starboard side, through a hole in the upper part of the knee next the stem, (or large triangular eye-bolt drawn through the stem, in some merchant ships,) then passed through the eye, 10, in the other end, and is brought down to its standing-part, and securely seized and crossed in two or three places, 11, 12, 13, (*Plate II. fig. 16.*) and the end capped; the heart is then seized in the bight above the bowsprit-chock.

The main-preventer-stay, 10, (*Plate III. fig. 1.*) sets up as the fore-stay, to a heart seized in the bight of its collar, which lashes round the fore-mast, on the fore-side through the eyes in the ends, or through bolts in the knight-heads or stem.

The mizen-stay, 11, (*Plate III. fig. 1.*) sets up through a thimble seized in the collar, which is lashed round the main-mast, about twelve feet up from the deck. A thimble is turned into the end of the stay, after it is reeved through the collar, and is set up with a laniard through an eye-bolt in the deck, abaft the main-mast.

The shrouds have a dead-eye turned into the lower ends, as 3, (*Plate II. fig. 15.*) left-handed, (being cable-laid rope,) with a throat-seizing, 4, clapt on close to the dead-eye; and above that a round-seizing crossed, 5, and the end of the shroud whipt with spun-yarn, and capped with canvas, 6, well tarred. The laniards, 7, are then reeved through the dead-eyes thus: the end of the laniard is thrust through the after-hole of the dead-eye in the shroud, and flopt with a walnut-knot; the other end is passed through the after-hole of its respective dead-eye in the chains, 8, then returns upwards, and reeves alternately through the holes in each, and is set taught with a tackle. It is customary to set up the shrouds the first time with temporary laniards of worn rope and spun-yarn seizings; and the proper laniards and seizings, when set up the last time for sea.

The tops, 12, 13, 14, (*Plate III. fig. 1.*) are gotten over their respective mast-heads by the girtlines.

The futtock-flaves are wormed, parcelled, and served with spun-yarn the whole length, in the house; and then cut to their lengths, as wanted, on board; and are seized along the lower shrouds horizontally, as much below the upper side of the trestle-trees as the cap is above. The shrouds are then *swiftened* together, thus: a spar is lashed to the outside of the shrouds, about a fathom below the futtock-flave; a single block is then lashed round each shroud and spar, except the foremost and aftermost shroud, so that all come in together; the swiftening-line is then reeved through each block from side to side, beginning in the middle, one end leading aft, the other forward; it then crosses, and reeves through two leading blocks, one on each side the deck, and is bowled tight, till the shrouds come in to the length of the catharpin-legs.

Catharpin-legs are four in number. The foremost is the shortest, and they increase an inch in length as they go aft. The length of the foremost one is from four feet in small, to eight feet in large ships. They have an eye spliced in each end, and then wormed, parcelled, and served with spun-

yarn the whole length, in the house. They are seized through the eye at each end, round the futtock-flave and shroud.

Ratlings, 23, 24, 25, (*Plate III. fig. 1.*) are fastened horizontally to the shrouds the first thirteen inches below the futtock-flave, and all the others the same distance asunder; they are fastened round each shroud with a clove-hitch, except at the ends, which have an eye, and seized round the shroud. The foremost and aftermost shrouds are left out for the first six ratlings down from the futtock-flave, and likewise the six lower ratlings next the dead-eyes. Small spars, or boats' oars, are seized to the shrouds, about five feet asunder, for the men to stand on to rattle down the shrouds. The swifters on the shrouds are next removed half way down between the dead-eyes, and bowled tight, and so remain as long as convenient.

The cap is next swayed up into the top by the girtlines.

*Bowsprit.*—*Horjes*, 15, (*Plate III. fig. 1.*) The outer ends are spliced round a thimble in the upper eye-bolt, on each side the bowsprit-cap. The inner ends have a thimble, seized in, and set up to an eye-bolt in the knight-heads on each side the stem with a laniard; the turns are *frapped* together, and the end hitched.

*Gammoning*, 16, 17 (*Plate III. fig. 1.*) The end of the rope is first whipt, then passed through the hole in the knee, (but where there is no knee, through a large triangular ring-bolt driven through the stem,) and over the bowsprit with a round turn, and clinched close against the cleats; the other end is passed through the fore part of the hole and over the bowsprit, crossing every turn, keeping each turn forward on the bowsprit and aft in the hole, from nine to eleven turns, and every turn is hove tight and *nipped*. The outer end of the bowsprit is swayed down by a chain-boat, or the ship's long-boat, loaded with casks of water, to make it fit close on the bed. When all the turns are hove tight, they are frapped together in the middle by as many cross-turns as are passed over the bowsprit, which are also hove very tight: the end of the gammoning-rope is then whipt, and seized to one of the turns.

*Bobstays* are wormed, parcelled, and served with spun-yarn three-fourths of their length; and their collars are fitted to the circumference of the bowsprit, with an eye spliced in each end; they are then wormed, parcelled, and served from eye to eye; and have a heart seized in the bight, with a long and short leg, with seven under and six riding turns, well frained and crossed with two turns; the end whipt, and secured with a walnut-knot, in the house. The bobstay-collar is lashed upon the upper side of the bowsprit at two-thirds out, or within the fiddle for the sprit-sail-slings, with from eight to ten turns through the eyes, and hove tight by a *beaver*. Ships in the navy generally have two pairs of bobstays, 18, 19, (*Plate III. fig. 1.*), merchant-ships commonly but one pair; one end is passed through a hole in the front of the knee, or large triangular eye-bolt in the stem; the ends are then spliced together. A heart, or dead-eye, is seized in the bight, the splice to come on the heart; it is then set up with a laniard, passing through the heart in the stay, and its collar by a luff-tackle.

*Shrouds*, 20, (*Plate III. fig. 1.*) are cable-laid rope; they have an iron hook and thimble spliced in the inner ends, and are served over the splice. They hook to an eye-bolt on each side the bow; the fore-ends have a heart, or dead-eye, seized in, and they are set up the same as the bobstays.

The use of the bobstays and shrouds is to draw down, and keep steady, the bowsprit; to counteract the force of the stays of the fore-mast, which draw it upwards.

*Topmasts.*—The girtlines may now be taken down from the

## RIGGING.

the lower mast-heads, and one of the top-blocks securely lashed round the mast-head below the cap. The end of a hawser is then led up from aft, outside the trestle-trees, and reeves through the top-block at the mast-head, then leads down inside the fore part of the trestle-trees, and reeves through the sheave-hole in the heel of the topmast, and is racked to the topmast in two or three places between the heel and the hounds; it is there well flopt with three-quarter lashing, and enough of the end left to make fast round the mast-head. The other end of the hawser is led to the capstan. When the topmast is hove high enough to enter the trestle-trees, the end of the hawser is made fast round the mast-head: the lower cap, 32, 33, 34, (*Plate III. fig. 1.*) is then lifted over the head of the topmast, and securely flopt with lashing a little below the hounds. The topmast is now hove high enough for the cap to enter over the lower mast-head, and then lowered, that the cap may be beaten down firmly on the mast-head with mallets; then the lashings may be cast off, and as the topmast is raised the rackings are cut loose.

Top-ropes-pendants have a large thimble spliced in the lower end, and are marled over the splice in the house, and pointed when on board. The top-ropes-pendant is then reeved through the top-block, which is hooked to an eye-bolt on one side the lower cap, next through the sheave-hole in the heel of the topmast, then led upwards, and made fast to an eye-bolt in the cap opposite to the top-block. Through the thimble, at the lower end of the pendant, is hooked the block of the top-tackle; its lower block is hooked to an eye-bolt in the deck, and the fall brought to the capstan. The girtline-blocks are now lashed to the topmast-head, and the topmast-crofs-trees and cap are swayed up into the top, and the crofs-trees, 35, 36, 37, (*Plate III. fig. 1.*) fixed on the mast-head.

Burton-pendants for the mizen-mast, 3, and topmasts, fore and main, 21, 22, (*Plate III. fig. 1.*), have a splice in the middle to the circumference of their respective mast-heads; thimbles spliced in their lower ends; and served with spun-yarn over the splices in the house. The burton-pendants are hoisted by the girtlines, and placed over the topmast-head, that the thimbles may hang on each side, to which are hooked the burton-tackles.

Shrouds are warped out on the floor, as the lower shrouds are, and fitted to the circumference of the topmast-head. In the foremast shroud, on each side, is seized a filter-block, 2, (*Plate II. fig. 14.*), below the futtock-flave, in the house. They are swayed up and placed over the topmast-head, 41, 42, 43, (*Plate III. fig. 1.*); the first pair to lead down on the starboard side forward, the next pair on the larboard side forward, and so on with the other two pair. The dead-eyes are turned in to their ends the same as the lower eyes are, and are set up with laniards to the dead-eyes in the futtock-plates by the burton-tackles.

Futtock-shrouds, 26, 27, 28, (*Plate III. fig. 1.*) The whole lengths are divided into four, and cut in the bights. Each length has a hook and thimble spliced in each end, and the ends of the splices flopt with spun-yarn; then doubled, and a spun-yarn tied in the middle for the cutting-mark. The hooks are then hooked in each other, and got upon the stretch. They will be well hove cut, in order to try the hooks and splices, as the topmast, &c. depends very much thereon. If a hook should break, or a splice draw, the former must be shifted, and the latter hauled tighter through. After they are sufficiently stretched, the ends of the splices are tapered, marled down, and served with spun-yarn within two feet of the cutting-mark; then cut asunder, and the ends whipt. On board, their upper ends hook to a hole in the lower end of the futtock-plates, and the lower ends of the

futtock-shrouds are made fast to the lower shrouds, with a round turn round the futtock-flave and shrouds, and seized up on the standing-part of the shroud with two seizings crossed.

Stays are swayed up and placed over the topmast-head next the shrouds, in their order thus: the breast-backstay first, and the standing-backstay next; then the topmast-stay; and, lastly, the topmast-preventer-stay.

Topmast-caps, 38, 39, 40, (*Plate III. fig. 1.*) may now be lifted on the topmast-head, and beat down firm; the girtlines unlashd and taken down, and the topmast hove up and fidded. Then set up the shrouds, 41, 42, 43, (*Plate I. fig. 1.*), and rattle them down, as before directed. Set up the breast-backstay, &c. thus: the *breast-backstay*, 44, 45, (*Plate III. fig. 1.*) has a single block turned into the lower end, with a throat and round-seizing, through which reeve the runner, one end of which is made fast to the chain-plates, abreast the mast, with a half-hitch, and the end seized down. In the other end is spliced a double block, connected by its fall to a double block that is strapped with an eye, through which a *span* is reeved, that has an eye spliced in each end, by which it is lashed to the chain-plates.

*Standing-backstays*, 46, 47, 48, (*Plate III. fig. 1.*) are set up, the same as a shroud, to a small dead-eye in the after-end of the channel.

*Shifting-backstays*, 49, 50, 51, (*Plate III. fig. 1.*) are clinched round the topmast-head and a thimble spliced in the lower end, to which is hooked a tackle, the lower block of which is hooked to an eye-bolt over the side, and frequently shifted, so as to render the topmast under a press of sail of the greatest assistance.

*Fore-topmast-stay*, 52, and *fore-topmast-preventer-stay*, 53, (*Plate III. fig. 1.*) are set up by passing the end through a sheave under the *bees* of the bowprit; then a long tackle-block is turned into the ends, which is connected by its fall to a single block hooked to an eye-bolt in the bow on each side, and set up with a luff-tackle, cat's-pawed to its fall. When the stay is set up, the parts of the tackle are flopt together with a rope-yarn, and the fall of the long-tackle is passed through the eye-bolt and arse of the block alternately till it is expended; the end is then made fast round all the parts with two half-hitches.

*Main-topmast-stay*, 54, (*Plate III. fig. 1.*) reeves through a single block, strapped with a long and short leg; the short leg has an eye spliced in it, the long leg goes round the foremast-head above the rigging, and through the eye of the short leg, and is turned back and seized. The stay, having a thimble turned in the lower end, leads down between the cat-harpins and the mast, and sets up with a laniard to an eye-bolt in the deck, close abast the mast.

The *preventer-stay*, 55, (*Plate III. fig. 1.*) reeves through a thimble seized in the bight of a collar, that is lashed close up to the *bibs* of the fore-mast, and then set up to an eye-bolt, as the topmast-stay.

*Mizen-topmast-stay*, 56, (*Plate III. fig. 1.*) reeves through a thimble seized in the bight of the collar, that is lashed close up to the *bibs* of the main-mast; a thimble is then spliced into the end of the stay, which is set up by its laniard to a thimble in another collar, that is lashed round the mast, a little below the cat-harpins.

When the stays are set up very tight, the shrouds and backstays must be cast off, and the mast-head gotten so far forward as nearly to touch the fore part of the partners by the runners and tackles, 29, 30, (*Plate III. fig. 1.*) or burtons of the mizen-mast, 31, (*Plate III. fig. 1.*) The pendants are strapped together abast their respective masts, and the runners made fast as far as convenient before the mast, and the falls led to the capstan or windlafs.

## RIGGING.

*Lower Yards.*—The lower yards must first be gotten on board thus: the hawser that hove up the topmast is made fast round the yard with a round turn and two half-hitches, securely stopt with spun-yarn along the yard in several places, and well stopt at the upper arm. As the yard is hove on board, the flops are cut, and the runner-tackle of the opposite side is brought on to the quarter of the yard, to assist it in lowering as the yard advances on board beyond the slings. They are laid athwartships before their respective masts, but the fore-yard must be kept above the main-stay by the runners, which are made fast round each quarter of the yard. They are then rigged as follows.

*Horses*, 1, 2, 3, (*Plate III. fig. 2.*) have an eye spliced in one end to the circumference of the yard-arm, and served with spun-yarn over the splice. The eye goes over the yard-arm, 1, and flops against the cleats, and the other end reeves through the thimble in the lower end of the stirrups, 2, which are from three to four in number: the inner end of the horses then have a thimble turned in, with a throat and round seizing, through which they are lashed to the yard, just beyond the sling-cleats on the opposite side. The stirrups, 3, (*Plate II. fig. 17.*) have their upper ends opened and plaited, and are fastened to the yard at equal distances with three round turns, and nailed, so as that the horses may hang suspended about three feet below the yard.

*Yard-tackle-pendants*, 4, 5, 6, 7, (*Plate III. fig. 2.*) have an eye spliced in one end the size of the yard-arm, 4, and a double block in the other end, 5, and the splices served over with spun-yarn in the house. The eye is put over the yard-arm next the horses, and the double block is connected by its fall to a single block strapped with a hook and thimble, 6, *Plate II. fig. 17.*

*Brace-pendants*, 8, 9, 10, 11, 12, 13, (*Plate III. fig. 2.*) have an eye spliced in one end, as in the former, and a single block in the lower end, and the splices served over with spun-yarn in the house. They, like the former, are next put over the yard-arm, 7, and the brace reeved through the single block, 8, (*Plate II. fig. 17.*) Sometimes in the navy, but mostly in merchant-ships, the block is lashed close up to the yard, without a pendant. *Fore-braces* have their standing-part made fast round the collar of the main-stay, on each side, with a hitch, and the end seized. The leading-part reeves through a single block, lashed on each side the main-stay-collar, close up to the rigging, and leads down and passes through a sheave in the brace-bitts, at the fore part of the quarter-deck. The *main-braces* have their standing part made fast with a clinch round an eye-bolt in the upper part of the quarter-piece: the leading-part reeves through a fixed block close aft upon the plank-keel, or a block lashed to an iron stay projecting on the side, and leads in and belays round a cleat on the inside. The standing and leading-parts of the main-brace are led aft through a thimble spliced in the end of a span with two legs, which is made fast with a half-hitch round the mizen-shrouds on each side.

*Preventer-braces* to the fore-yard, in war, reeve through a block lashed round the yard-arm, 9, (*Plate II. fig. 17.*) and through a block in a span, hitched round the bowsprit-cap; they lead in upon the forecastle, and the standing-part makes fast round the cap. Those to the main-yard reeve through the block on the yard-arm, then through a block lashed to the fore-shrouds, close below the cat-harpins, lead down upon the forecastle, and the standing-part makes fast to the shrouds above the block with a hitch, and the end is seized.

*Top-sail-sheet-blocks* are next put over the yard-arms, 8, 9, 10, 11, (*Plate III. fig. 2.*), strapped with an eye to the size of the yard-arm, 10, *Plate II. fig. 17.*

*Lift-blocks* are then spliced into the straps of the top-sail-sheet-blocks, 11, (*Plate II. fig. 17.*); the lifts, 12, 13, 14,

15, 16, 17, (*Plate III. fig. 2.*) reeve through a block in a span, hitched round the mast-head, between that and the top-mast, then lead down abreast the shrouds, and reeve through a block fastened to the side, and there belay.

*Quarter-blocks*, 18, 19, (*Plate III. fig. 2.*) are strapped with a long and short leg, with a lashing-eye spliced in each end, through which they lash round the middle of the yard, within the cleats, the block hanging downwards, 11, *Plate II. fig. 17.*

The quarter-block is a double block, with a thick and thin sheave running on the same pin, through which reeve the top-sail-sheets, and the thin sheave is intended for the clue-lines; but a single block, in lieu of them, is recommended, as they would lead fairer and work easier. Large merchant-ships have a single block lashed on each side of the middle of the yard, and the sheets reeve on their respective sides, and lead down by the sides of the mast. Smaller ships have a double block lashed in the middle of the yard, as the quarter-block, through which the sheets reeve, and lead down on opposite sides.

*Clue-garnet-blocks*, 12, (*Plate II. fig. 17.*) lash through the eyes upon the yard, the blocks to hang downwards, four feet without the sling-cleats, on each side.

*Lecch-line-blocks*, 13, (*Plate II. fig. 17.*) are lashed through the eye and round the yard, ten feet within the cleats at each yard-arm. The blocks to hang on the fore-side of the yard.

*Bunt-line-blocks*, 14, (*Plate II. fig. 17.*) are lashed, like the former, midway between them and the slings.

*Slab-line-blocks*, 15, (*Plate II. fig. 17.*) are strapped with a short lashing-eye, and are seized to the span of the quarter-blocks underneath the yard.

*Tricing-blocks*, 16, (*Plate II. fig. 17.*) for the yard-tackles are strapped as the above, and are seized round the yard about one-third the length within the arm-cleats. The blocks to hang under the yard.

The *inner tricing-line*, 20, (*Plate III. fig. 2.*) reeves through a block lashed to the futtock-stave, has a long-eye spliced in the outer end, the bight is put over the hook of the single block with a couple of turns, 17, (*Plate II. fig. 17.*), and the leading-part belays to the shrouds. At sea it is hooked to a becket, or strap, round the futtock-staff. The *outer tricing-line*, 21, (*Plate III. fig. 2.*) is spliced round the strap of the yard-tackle-block, 18, (*Plate II. fig. 17.*), and reeved through a block on the yard, it then reeves through a block lashed in the shrouds near the futtock-staff, and leads down upon deck.

*Jeers*, in large ships, are two large tackles, 22, 23, (*Plate III. fig. 2.*) The blocks at the mast head are hove up close on each side by the top-burton-tackles, and so lashed, that every turn of the lashing is alternately passed through the strap of the block (*Plate II. fig. 11.*), and over a broad elm-cleat, nailed on the opposite side of the mast-head, and the ends of the lashing are well stopt. The other two blocks are strapped with a double strap to the size of the yard, with a long and short leg (*Plate II. fig. 10.*) (See *Strapping of Blocks*, below.) They lash on each side the middle, or slings, within the cleats, 19, 20, (*Plate II. fig. 17.*) The long leg of the strap is passed down the aft-side of the yard, and meets the bight of the short leg on the fore-side, and lashes, every turn passing alternately through each bight, rose-fashion. The falls reeve through the blocks at the mast-head and on the yard, and lead down upon deck. Jeers, in merchant-ships, and small ships in the navy, have two single blocks lashed on each side the mast-head, as above, and another, the same size, in the middle of the yard. The *tye* then reeves through one of the blocks at the mast head, then through the block on the yard, and then through the block

# RIGGING.

on the opposite side of the mast-head. In the lower ends of the tye is spliced a double block, with its fall, which reeves through another double block, that hooks to an eye-bolt in the deck. The fall of the jeers leads through the bits to the capstan, by which the yards are hoisted up in their place.

*Trufs-pendants* are doubled, and cut in the bight; they have a thimble spliced into one end, and are served with spun-yarn one-third the length, in the house. The ends that have the thimbles are passed round the yards within the sling-cleats, and are well seized. One end passes over the yard, the other under, and both ends round the mast. The starboard end reeves through the larboard thimble, and the larboard end through the starboard thimble. The lower end has a double block turned in, with a throat and round-seizing, and its fall reeves through a double block that hooks to an eye-bolt in the deck, on each side the mast, by which the trufs-pendant is straightened or slackened, consequently the yard is close confined, or removes from the mast.

The *nave-line* reeves through a single block lashed under the aftside of the top, and through a block or thimble seized to the trufs-pendants; one end leads upwards, and makes fast round the trestle-trees. The leading-part goes down upon deck.

*Slings and Straps.*—The strap has an eye spliced in each end, with a long and short leg, to the circumference of the yard, and served with spun-yarn from eye to eye, with a thimble seized in the bight. The slings have an eye spliced in one end, then wormed, parcelled, and served almost the whole length, in the house.

The long leg of the strap passes down the aftside of the yard, exactly in the middle, comes up the fore-side, meets the short leg, and lashes through the eyes, the thimble to be upwards. The slings have a large thimble seized to the bight with a long and short leg. The long leg passes round the after-part of the mast, and reeves through the eye in the short leg; it is then returned back, and securely seized to its own part in several places. By these the yards are slung at the mast-head by a laniard, that splices in the thimble in the slings at the fore-part of the mast, and then reeves through the thimble in the strap upon the yard, and alternately till the laniard is expended; the end then fraps round the turns, and makes fast with two half-hitches. In time of action, the yards are slung with chains.

## Strapping of Blocks in the House.

A TABLE of the Dimensions of Straps for Lashing and Seizing Blocks.

Size of the Blocks.	Size of the Straps.	Length of the Straps.	
		Feet.	Inches.
17	5	7	6
16	4½	6	9
15	4	6	0
14	3½	5	6
13	3½	5	0
12	3½	4	6
11	3	4	3
10	3	3	9
9	2½	3	6
8	2½	3	0
7	2½	2	9
6	2	2	6
5	1½	1	9
4	1½	1	6

The whole length of all the different sizes of block-strap is gotten upon the stretch, and hove out tight for worming and serving; after that is performed, it is cut into lengths agreeable to the above table, according to the size of the blocks. The scores of all blocks, if required, are to be opened, or eased, so as to receive the strap, and then to be well tarred, and the pin and sheave examined, before the strap is put on (*Plate II. fig. 1.*) The block is then set well into the straps with wedges, thus: the strapping is frapped together with rope-yarn under the block, with a chock between, and the wedges are set between the breast of the block and the chock. The strap is next nippered, with a heaver, round the block; the wedge, chock, and frappings are then removed, and the block hung up, that the strap may be well seized together, close under the block, with nine under and eight riding turns; every turn strained tight round with a heaver, and crossed each way with two turns.

*Jeer-blocks* (*Plate II. figs. 10, 11.*) are double scored, consequently strapped with a double strap, thus: it is spliced together at the ends, and when doubled, should be the size of the block and the circumference of the yard. It is then doubled, and the block seized in the bight, with a long and short leg, the splice lying in the arse of the block. Jeer-blocks for the mast-heads are strapped with long-eyes, to receive many turns of the lashing.

Blocks strapped with a thimble, or hook and thimble, (*Plate II. fig. 3.*) have the ends of the straps spliced together. The block is fixed in one bight, for the splice to lay, as above, and the thimble in the other bight; the seizing is clapt on, between the block and the thimble, with eight under and six riding turns, according to the size of the block; each turn strained by a heaver, turns double-crossed, and the end flopt with a wall-knot crowned.

Blocks strapped with eyes (*Plate II. figs. 4, 5, 6.*), or thimbles spliced in the ends, are seized tight into the bight, and the legs left long enough to lash through the eyes, round their respective mast, yard, &c. as the topfail, clue-lines, clue-garnets, &c.

Blocks strapped with double tails are seized in the bight as the former; but those with a single tail are spliced in, and served with spun-yarn over the splice.

The strapping of jeer-blocks is wormed, parcelled, and served. Strapping of four inches diameter, and above, is wormed and served; and all under four inches is only served with spun-yarn; except the spritsail-brace, buntline, and lee-line blocks, that are lashed under the tops, which are only served with spun-yarn over the splice, and the tail left half a fathom in length.

## Rigging the Topfail-Yards.

The topfail-yards are first hove on board by the top-rope, which is fastened to the slings of the yard, and flopt from thence with spun-yarn to the yard-arm, and placed athwart their respective masts.

*Horses, 1,* rig the same as the lower yards, with the addition of *Flemish horses, 2,* (*Plate II. fig. 18.*) which have an eye spliced in each end; one eye is put over the eye-bolt in the yard-arm, and the other is seized round the yard within the arm-cleats, 24, 25, 26, *Plate III. fig. 2.*

*Brace-pendants, 3,* (*Plate II. fig. 18.*) are next put over the yards, as on the lower ones. The fore-topfail-braces reeve through the block in the pendant, and then through a block lashed on each side to the main-flay-collar, a little below the fore-braces; the standing-part makes fast to the flay with a hitch, and is seized below the block. The leading-part leads from the block on the collar, through a block lashed on the

## RIGGING.

ftay, over the fore hatchway, and through a block strapped with a thimble into an eye-bolt in the aft-part of the fore-castle, and belays to a pin in the skid-beams, 27, 28, *Pl. III. fig. 2.*

The main-topfail-braces reeve through the block in the pendant, and the standing-part makes fast to the mizen-ftay collar. The leading-part reeves through a block in the span round the mizen-mast-head below the hounds, and through a sheave-hole in the mizen-topfail-sheet-bitts, abaft the mizen-mast, and belays there; 29, 30, *Plate III. fig. 2.*

The mizen-topfail-braces reeve through the block in the pendant. The standing-part makes fast round the peek-end, and the leading-part reeves through single blocks at the peek, and comes down and belays to the fore-side of the taffarel to a cleat; 31, 32, *Plate III. fig. 2.*

*Reef-tackle-pendants*, 4, (*Plate II. fig. 18.*) reeve through the upper sheave in the *flyer-block* in the topmast-shrouds, thence through a sheave-hole in the yard-arm, and are stopt with an over-hand knot, till the sail is bent. A double block is turned in to the lower ends of the pendants, and its fall reeves through another double block, that is seized to the after-part of the lower trestle-trees, and the falls lead down upon deck; 33, 34, 35, 36, *Plate III. fig. 2.*

*Lift-blocks*, 5, (*Plate II. fig. 18.*) are strapped with an eye to the size of the yard-arm. The lift reeves through the lower sheave in the filter-block in the topmast-shrouds, and through the block on the yard-arm. The standing-part hooks to a becket round the top-mast-cap, and the leading-part leads down the side of the mast, and belays to the dead-eyes in the lower shrouds; 37, 38, 39, 40, 41, 42, *Plate III. fig. 2.*

*Tye-blocks*, those at the topmast-heads, lash close up to the rigging, under the collar of the ftay; and the blocks on the yard, 6, (*Plate II. fig. 18.*) lash under the fore-part of the yard, as the lower ones. The standing-part of the double-tyes in large ships clinch round the mast-head, then reeve through the double block upon the yard, return upwards, and reeve through the block on each side the mast-head; 43, 44, 45, (*Plate III. fig. 2.*) The fly-blocks are then spliced in their lower ends, and connected by their haliards to a single block, that is strapped with a long strap, with a hook and thimble, that hooks to a swivel-eye-bolt in the channel on each side: the leading-part comes in-board through a block lashed on each side; the foremost ones abaft the fore-castle, and the after-ones on the quarter-deck. A single tye rigs like the lower yards in small ships.

*Buntline-blocks* are spliced round the straps of the topfail-tye-block upon the yard, 7, *Plate II. fig. 18.*

*Clue-line-blocks* are strapped with two lashing-eyes, and lash upon the yard, three feet without the slings, the blocks hanging under the yard, through which the clue-lines reeve and lead down upon the deck, 8, *Plate II. fig. 18.*

*Top-gallant-sheet-blocks*, 9, (*Plate II. fig. 18.*) are strapped with two lashing-eyes, and lash upon the yard, close within the clue-line blocks on each side.

*Parral.* (*Plate II. fig. 20.*) The parral-ropes in the house have an eye spliced in each end, are wormed and served with spun-yarn from eye to eye, then doubled, and cut afunder in the bight. The end of one rope is thrust through the upper hole in the ribs, and a truck, alternately. The end of the other rope is passed through the lower hole in the ribs and a truck the reverse way. The parral is fitted to the aft-side of the topmast, and the eye in one end passed under the yard, and the other over, till both eyes meet and are seized together on the fore-side with spun-yarn. The other ends of the parral-rope are passed round the yard and aftside of

the parral alternately, till the latter is well secured to the former; and the whole of the turns are marled together with quarter-seizings, to confine them close in the cavity on the aftside of the ribs. Thus the yard is confined to the mast, but easily hoisted or lowered when the mast is kept clean and greased.

*Jib-boom to be rigged.*—The jib-boom is hoisted on board and laid on the bowsprit, and its fore end pointed through its hole in the bowsprit-cap. The heel-rope or top-rope may be reeved through the sheave-hole at the heel, and one end made fast to the eye-bolt on one side of the bowsprit-cap, the other reeved through a single block made fast to an eye-bolt on the opposite side, and lead in upon the fore-castle, 46, *Plate III. fig. 2.*

The *traveller* is first put over the outer end of the jib-boom, and the hook kept inwards; 47, *Plate III. fig. 2.*

*Horses* are doubled, and served with spun-yarn one fathom in length in the bight, and knotted with an over-hand knot, at the distance of every yard, in the house. On board, the bight is taken over the outer end of the jib-boom, with a jaming-knot, close against the stop, which prevents them coming in. The inner ends are brought aft and made fast, with a round turn round the jib-boom, within the cap. The ends are stopt back with two or three seizings of spun-yarn, to prevent their being cast off by mistake; 57, *Plate III. fig. 1.*

*Guy-pendants* are put over the jib-boom, the same as the horses, and the inner ends reeve through a thimble, on the quarters of the spritfail-yard, and turn in to the strap of a double block, with a throat and round-seizing, and its fall reeves to a single block, that hooks to an eye-bolt near the cat-head, and leads in upon the fore-castle; 49, 50, *Plate III. fig. 2.*

A *strap* is put over the end of the jib-boom, with three thimbles seized in it; the middle thimble is the largest, and reeves the fore-top-gallant-ftay, and the smaller thimbles on each side the fore-top-gallant-bowlines.

The *spritfail-yard* is hove on board, and laid fore and aft the fore-castle for rigging with its *horses*, 51, 52, (*Plate III. fig. 2.*) The eye in the outer end is put over the yard-arm on each side, and stops against the cleats. The eye in the other end is well seized to the yard, at three feet beyond the slings, with *flirruks* and *Flemish horses*, the same as the topfail-yards, 53, *Plate III. fig. 2.*

*Braces and Pendants.*—The eye in one end of each pendant goes over the yard-arm close against the horses, and the brace reeves through a single block spliced in the other end; the standing-part makes fast to the ftay-collar, and the leading-part reeves through a double block, made fast under the fore-top, and then leads through another, made fast to the aft-part of the top, and down to the aft-part of the fore-castle; 54, 55, *Plate III. fig. 2.*

*Lifts.*—The blocks are strapped with an eye to the size of the yard-arm, and driven thereon close to the braces. The lift reeves through a single block in the end of a *span*, which is passed with a hitch round the cap under the jib-boom, and through the block on the yard-arm, and the standing-part returns upwards, and is made fast to an eye-bolt in the side of the cap; the leading-part comes in upon the fore-castle. They are occasionally used for spritfail-topfail-sheets.

The *standing-lift* has an eye spliced in one end, and lashes to the yard one-fourth from the slings: the other end has a thimble spliced in, and is set up with a laniard to a thimble spliced in a strap that is hitched round the bowsprit within the *bees*; 56, 57, *Plate III. fig. 2.*

*Clue-line-blocks* are strapped with two eyes, and are lashed

lashed through those eyes round the yard three feet without the slings, the lashing to be upon the yard.

The *strap* has a thimble seized in the bight, and is spliced or seized round the yard in the middle, between the cleats. Also on each quarter of the yard is seized a strap, with a thimble, through which are led the jib-guys. The yard may now be hove out towards its place, and the long-tackle block of the haliards hooked into an eye-bolt in the after-part of the bottom of the bowsprit-cap; the hook to be moused with spun-yarn, to prevent its slipping loose. The single block is hooked to the thimble in the strap at the slings, and the fall then leading in upon the forecastle, the yard is hove to its place.

The *slings* have an eye spliced in each end, one of which goes round the yard close within the cleats near the middle, and seizes with a quarter-seizing close to the yard; the other end goes over the bowsprit before the fiddle, and under the yard, then over the bowsprit again, till the eyes in the ends, meeting close together, are well lashed.

*Preventer-slings* are used when the haliards are taken in. The outer end has a hook and thimble spliced in and served down over the splice, that hooks to the eye-bolt in the bottom of the cap. The inner end reeves through the thimble in the strap at the slings, and is hitched with two half-hitches, or spliced.

The *sprit/sail-top/sail-yard* is hove on board, &c. as the former, and the

*Horses*, having an eye in their outer ends, are put over the yard-arm on each side, and stop against the cleats; the inner end has an eye, which is seized to the yard, three feet without the slings, 58, *Plate III. fig. 2.*

The *braces* have an eye spliced in one end, that goes over the yard-arm on each side; the inner ends lead through a block made fast to the under side of the fore-top, from thence through another at the aftside under the top, and lead down to the aft-part of the forecastle, and there belay; 59, *Plate III. fig. 2.*

The *lifts* have an eye spliced in their outer ends, and are driven over the yard-arm close to the braces; the inner end reeves through a thimble, seized on each side a strap hitched over the end of the jib-boom, and leads in upon the forecastle through a fiddle on the bowsprit, and belays to the rack over the bowsprit, 60, *Plate III. fig. 2.*

The *clue-line-blocks* are strapped with two eyes, and are lashed through those eyes round the yard, about two feet without the slings.

*Haliard*.—The standing-part is made fast with a bend through the becket of its block, lashed under the outer end of the jib-boom; then reeves through a single block, lashed round the middle of the yard between the cleats; then forward, and reeves through the block at the outer end of the jib-boom, and leads in upon the forecastle, and belays to a rack over the bowsprit, 61, *Plate III. fig. 2.*

*Top-gallant Masts*.—The *top-rope* reeves for the top-gallant-mast as it does for the topmast, observing to stop it to the top-gallant-mast-head with spun-yarn, to keep it steady till it has entered the topmast-cap; the stop is then cut, and the end of the top-rope made fast to the eye-bolt in the topmast-cap.

A grommet of rope, spliced to the size of the mast, is first put over the head, and beat down close to the stop of the bounds.

*Shrouds, backstays, and stays*, are fitted in the house, and hoisted over the top-gallant-mast-head, the same as the topmasts, and the top-gallant-mast is then swayed up and sided.

The *shrouds* are then thrust through a hole in the end of

the topmast cross-trees, and between the topmast shrouds, over the futtock-staff. A thimble is seized in the ends that fet up with the laniard through a thimble seized in the bight of a strap, made fast round the futtock-plates, close under the dead-eyes, with a turn through the bight, 58, 59, 60, *Plate III. fig. 1.*

*Backstays* fet up, the same as the topmast-backstays, to a small dead-eye in the aft-part of the channel, or in a stool abaft the channel, 61, 62, 63, *Plate III. fig. 1.*

*Fore-top-gallant-stay*, 64, (*Plate III. fig. 1.*) reeves through a single block in large ships, or a thimble in the strap at the outer end of the jib-boom of frigates and smaller vessels. The former fets up by its tackle to an eye-bolt in the head; the latter with a jigger-tackle occasionally, and is secured by a laniard to the gammoning or eye-bolt in the head.

*Main-top-gallant-stay*, 65, (*Plate III. fig. 1.*) is cable-laid in large ships, and fitted with a collar and moused, as the lower stays. Smaller ships are hawser-laid, have an eye spliced in the upper end to the circumference of the mast-head, and served with spun-yarn over the splice, in the house. It reeves through a single block at the fore-topmast-head, has a thimble turned into the end of the stay, and fets up to a thimble in a span, made fast to the trestle-trees of the foremast by its laniard.

*Stay/sail-stay*, 1, (*Plate IV. fig. 1.*) is spliced into the top-gallant-stay, one fathom below the top of the mast, it then reeves through a block or thimble lashed to the fore-topmast-head, takes a turn round the trestle-trees, and belays there.

*Mizen-top-gallant-stay*, 66, (*Plate III. fig. 1.*) fets up to the main-topmast-head, as the main-top-gallant-stay fets up to the fore-topmast-head.

*Flag-staff-stays* go round their respective top-gallant or royal mast-heads with a running-eye, and are kept close up under the truck, by a small cleat nailed on each side. The fore one reeves through a thimble at the jib-boom end, and belays round the fore-stay-collar. The main one reeves through a thimble above the fore-top-gallant rigging, and belays in the top. The mizen one the same above the main-top-gallant rigging.

Royal masts are rigged as top-gallant-masts, and often abaft the mast.

The *top-gallant-yards* are hove on board, and rig with horses, braces, and lifts, over the yard-arm, the same as the top/sail-yards.

*Braces*, 1, (*Plate II. fig. 19.*) The fore-top-gallant-braces, 56, (*Plate III. fig. 2.*) reeve through the block in the pendant of large ships, or the block in the yard-arm of small. The standing-part makes fast with a hitch, and the end seized back round the collar of the main-topmast-stay on each side; and the leading-part reeves through a block lashed round the collar a little below the standing-part; then leads through a block at the aft-part of the fore-top, and belays to a pin at the aftside of the forecastle.

The *main-top-gallant-braces*, 57, (*Plate III. fig. 2.*) reeve as the former. The standing-part makes fast with a hitch, and the end seized back round the collar of the mizen-topmast-stay, and the leading-part through a block seized just below the standing-part, and leads down into the mizen-shrouds.

The *mizen-top-gallant-braces*, 58, (*Plate III. fig. 2.*) are single, and go with a splice over the yard-arm. They lead through a thimble at the mizen-peek, come down, and belay to a cleat on the fore-side of the taffrail.

The *lifts*, 59, 60, 61, (*Plate III. fig. 2.*) are single, and go over the yard-arm with an eye; the other end reeves through

through a thimble in the top-gallant shrouds, leads down into the top, and belays round the dead-eyes.

*Clue-line-blocks*, 2, (Plate II. fig. 19.) are strapped with two lashing-eyes, and lash upon the yard three feet without the slings. The clue-line reeves through the block which hangs under the yard, which is flopt with a knot till the sail is bent. The leading-part comes down the mast, and belays to the shroud-rack.

The *tye*, 3, (Plate II. fig. 19.) reeves through the sheave-hole in the top-gallant-mast hounds, and clinches round the yard at the slings; in the lower end is turned a double or single block, according to the size of the ship, through which reeves the haliard, and through a single block lashed to the after-part of the lower trestle-trees, under the top, and belays round the cross-piece of the bitts abaft the mast.

*Parral*, the same as the topfail-yard, after the yard is swayed up.

#### *Rigging of Royal-Yards.*

When they have royal masts, they rig as the top-gallant-yards above; but if there are no royal masts, they set flying; that is, the *haliard* reeves through a sheave-hole close up under the truck; the standing-part clinches to the middle of the yard, and the leading-part comes down and belays in the top.

#### *Rigging of the Mizzen-Yards.*

Mizzen-yards are now seldom used, and that only in line of battle ships in the navy, and large East India ships.

They are hove on board as the lower yards, and the

*Derrick-block* is strapped with two eyes, that go round the yard and lash underneath, between the slings and outer yard-arm or peek. The *Derrick-fall* reeves through the double block that is cross-feized in the strap, has an eye spliced in each end, and lashes to the mizen-cap; then through the single block upon the yard. The standing-part is again taken up and reeved through the block at the mizen-cap; an eye is then spliced in the end to the size of the yard-arm, that jams over the peek-end. The leading-part comes from the double block at the cap, leads down through the trestle-trees to a block in the larboard, mizen channel, and through the side upon deck.

*Brail-blocks* are strap together in one strap, and lie over the yard, and seized together underneath; the throat-blocks next the cleats near the mast; the middle-blocks in the middle between the throat-blocks and the peeks; the peek-blocks about three or four feet within the cleats at the peek.

*Vangs*.—The pendants are doubled, and served with spun-yarn two fathoms long in the bight, and a double block spliced in each end, and served with spun-yarn over the splice in the house. The bight is put over the peek-end with a litch. The falls reeve through the double block in their ends, and a single block is hooked to an eye-bolt in the quarter-piece on each side. The standing-part makes fast to the becket of the single block, and the leading-part from the double block, belays to a cleat on the taffrail.

*Signal haliard-block* is lashed to an eye-bolt in the peek of the yard.

*Jeers*.—The fall reeves through a treble or double block lashed at the mast-head, and likewise a double or single block lashed between the sling-cleats, and the leading-part comes into the mizen-chains on the starboard side as the derrick did on the larboard side. The yard is then swayed up, and the fall made fast with a hitch, and seized.

*Slings* go round the mast-head, and round the yard between the sling-cleats, which are kept abaft the mast.

*Bowlines* reeve through a single block strapped with a thimble into an eye-bolt, in the lower end of the yard, and through a block hooked to an eye-bolt in the side abreast the lower end of the yard, or lashed to the mizen-shrouds.

*Horse* for the mizen-sheets clinches to an eye-bolt on each side the fore part of the taffrail with a thimble, to which is strapped the sheet-block.

*Gaff*.—If the mizen-yard is not used, there must be a *gaff*, 20, (Plate IV. fig. 1.) as in smaller vessels, which is rigged similarly to the mizen-yard, excepting only that it has a throat-haliard instead of jeers, which hooks to an eye-bolt over the jaws; and a span instead of a derrick, 21, Plate IV. fig. 1.

The *driver* or *spanker-boom* rigs with a *topping-lift*, 25, (Plate IV. fig. 1.) which goes over the outer end of the boom with a clove-hitch, and stops against the shoulder; the ends are reeved through a single block lashed on each side of the mizen-mast-head; then have a double block spliced in each lower end, which reeves with its fall to a single block, hooked to an eye-bolt in each mizen-channel. The standing-part makes fast to the becket of the single block, and the leading-part belays to a cleat on each side of the mizen-mast.

*Guy-pendants*, 26, (Plate IV. fig. 1.) have a hook and thimble spliced in one end, that hook to a thimble on each side of a trap spliced round the boom, over the horse at the fore-side of the taffrail; a thimble is spliced in the inner ends of the pendants, to which is hooked the tackle on each side, that are used where most support can be given to the boom.

#### *Rigging and Bending the Sails.*

Rigging and bending the fore-course, 5, (Plate IV. fig. 2.) This sail is hoisted on board by the yard-tackles, and laid athwart the main-stay, ready for bending, thus; the *sheet-block* is strapped with an eye, and put over the clue on each side. The tack is next thrust through the clue for the knot to come on the aftside.

*Clue-garnet Block*.—The eyes of the strap are put through the clue, brought up on each side, and seized on the top.

*Tacks* are cable-laid, and tapered in the making. The biggest end is opened out long enough to heave the knot close together; the knot is double-walled and crowned; the ends are thrust through the walling, then scraped down, served over with spun-yarn, and are wormed, parcelled, and served with spun-yarn one-fourth of the whole length, in the house. (Plate I. fig. 14.) *Single tacks*, as the above, reeve through the block lashed round the outer end of the boomkin, on each side; then lead in upon the fore-castle or upper deck, and belay round a large cleat upon the cat-tail, or the bitts near the mast. In *double tacks*, the standing-part makes fast round the outer end of the boomkin, and the leading-part reeves through a single block lashed to the clue of the sail, then through the block at the outer end of the boomkin, and leads in as the above, 21, Plate IV. fig. 2.

*Sheets*, 23, (Plate IV. fig. 2.) are reeved through the sheet-block at the clues, and the standing-part seizes or splices with a thimble to an eye-bolt in the side a little before the gangway. The leading-part reeves through a sheave in the side above the eye-bolt, leads forwards, and belays round a large cleat in the side.

*Yard-ropes* are temporary, and are only used to get up the sail; they reeve through tail-blocks, that are made fast round the boom-iron at each yard-arm, and one end comes

## RIGGING.

down and makes fast to the upper reef-earring cringle. The leading-part comes in upon deck, through a leading-block lashed to a timber-head or eye-bolt. The fail is then run up to the yard, where the men go and pass the

*Earrings*: one end of the earring splices to the head-cringle with a long-eye; the other end passes over the yard-arm, without the rigging, and through the cringle alternately, two or three times, and likewise passes round the yard, within the rigging, and through the cringle, till the earring is expended, making fast the end with two half-hitches. The outer turns are to stretch the head of the fail tight along the yard, and the inner turns to draw it close up.

*Reef-earings*, when used, the same.

*Rope-bands*, which fasten the head of the fail along the yard, are braided cordage, with an eye in one end, and one leg longer than the other. The eye of the long leg is put over the short leg, and the eye of the short leg is thrust through the eye-let hole at the aftside of the fail, and passes through the eye of the short leg; and so of the rest. The rope-bands, being previously reeved through the head of the fail, fasten to the yard as follows. The long leg comes over the yard from the fore-side, with a round turn between the head of the fail; the short leg comes up the aftside, and makes fast with a reef-knot upon the yard. The fail is then let fall to see it is clearly bent.

*Points* are usually put in the fail at the fail-loft. See *SAIL-MAKING*.

*Gaskets* are braided cordage, which go round the yard with a running-eye, two on each quarter, and one at each yard-arm: the bunt-gasket in the middle has two legs, and lashes to the yard on each side of the quarter-blocks. These are used when the fail is *furled*, to bind it firmly up to the yard, by passing the gasket six or seven times round the yard and fail, each turn a certain distance apart, or spirally, making fast the end with two half-hitches.

*Clue-garnets*, 24, (*Plate IV. fig. 2.*) reeve through their block upon the yard on each side, then through the block at the clue of the fail. The standing-part is carried up, and made fast round the yard by its block with a timber-hitch, and the end stopped. The leading-part comes down upon deck, and reeves through its sheave-hole in the top-fail-sheet-bitts, and there belays.

*Bowlines*, 25, (*Plate IV. fig. 2.*) reeve through a single block lashed round the collar of the fore-stay, or the fore-preventer-stay on the bowsprit, and the outer part reeves on the howline-bridle, with a thimble spliced in the end, and the bridle clinches to the cringle on the leech of the fail. The leading-part comes in upon the fore-castle, and belays to the fore-top-fail-sheet-bitts.

*Leech-lines*, 26, (*Plate IV. fig. 2.*) reeve through the spritsail-brace-block, under the top, then through the block upon the yard, and the standing-part makes fast with a clinch to the upper bowline-bridle; the leading-part then reeves through a double block, at the aft-part of the top, and comes down upon the fore-castle.

*Bunt-lines*, 27, (*Plate IV. fig. 2.*) reeve through the leg and fall-block, and through a double block at the aft-part of the top, and through the blocks upon the yard, and lead down the fore-side of the fail, and clinch to the cringles in the foot. The fall reeves through the leg-block; the standing-part makes fast to an eye-bolt near the mast, and the leading-part through a live-block under the cross-piece of the bunt-bitts.

*Slab-lines*, 28, (*Plate IV. fig. 2.*) reeve through a small block lashed to the strap of the quarter-block, and the standing-part clinches with two legs to the middle bunt-

line cringles. The leading-part leads to the top-fail-sheet-bitts, and belays to the cross-piece.

*Spilling-lines*, 29, (*Plate IV. fig. 2.*) reeve through blocks lashed on each side of the quarter-blocks of the lower yards, then lead down before the fail, return upwards under the foot of the fail, and make fast round the yard with a timber-hitch.

*Life-lines* are sometimes used for the preservation of the seamen. They are generally of worn hawser-laid rope, and are made fast with the two half-hitches round the strap of the lift-block, and jee or tye-block, in the middle of the yard.

*Rigging and Bending the Main-Course*, 1, *Plate IV. fig. 2.*

This fail is hoisted on board, and laid athwart, ready for bending, as the fore-course. Sheet-blocks, tacks, and clue-garnet-blocks, are fitted in the clues as the fore-course.

Tacks, single, 31, (*Plate IV. fig. 2.*) reeve through the sheave-hole in the chestree, on each side, and lead on board through a sheave-hole in the side, and belay round a range-cleat in the waist.

Tacks, double, 32, (*Plate IV. fig. 2.*) The standing-part clinches to an eye-bolt before the chestree, and the leading-part reeves through a single block lashed to the clue of the fail; then leads in upon deck, through the chestree and sheave-hole in the side, and belays as the above.

*Sheets*, 33, (*Plate IV. fig. 2.*) reeve through the sheet-block at the clues. The standing-part is seized to an eye-bolt with a thimble on the quarters; the leading-part comes on board through a sheave-hole in the side, and belays to a range-cleat in the waist. The present custom is for the leading-part of the sheets to reeve through a block lashed to the eye of an iron stay, projecting from the side, called a *spider*, and comes in upon deck through a port that has a roller fitted vertically at its aftside.

*Yard-ropes and bending*, as the fore-course.

*Earrings, rope-bands, points, gaskets, and clue-garnets*; as the fore-course.

*Bow-lines*, 34, (*Plate IV. fig. 2.*) reeve through a double block, lashed round the fore-mast five feet above the fore-castle, and the outer part reeves upon the long leg with a thimble. The lower bridle is the longest, and clinches to the lower cringle on the fail. In the other end is spliced a thimble, through which reeves the upper leg, that clinches to the upper cringle. The starboard bow-line belays on the larboard, and the larboard bow-line leads over and belays on the starboard side. Four feet from the bridle on each bow-line is spliced a thimble, and pointed over, called a *lizard*, to which is hooked a bow-line tackle that makes fast to the bitts, and is bowfed upon until the bow-line can be made fast to the bitts.

*Leech-lines*, 35, (*Plate IV. fig. 2.*) reeve through the block upon the yard, and the outer end makes fast with a clinch to the upper bow-line bridle. The leading-part reeves through a double block at the fore part of the top, and another at the aft part of the top. A single block is turned into the lower end, and a whip-fall reeved through it. The standing-part makes fast to an eye-bolt in the deck; and the leading-part reeves through a block under the cross-piece of the bitts, near the mast.

*Bunt-lines*, 36, reeve as the fore-course, and lead forward upon the fore-castle.

*Slab-lines*, 37, *spilling-lines*, 38, and *life-lines*, 39, (*Plate IV. fig. 2.*) as the fore-course.

## RIGGING.

*Rigging and Bending the Mizzen-Course*, 9, *Plate IV. fig. 2.*

*Earing* reeves, with an eye in one end, through the cringle in the peek of the fail, and makes fast round the peek as the earings above.

The nock-earings the same as the peek.

*Lacing* is spliced to the peek-earring-crinkle, and laces round the yard or gaff, through the eye-let holes in the head of the fail, and makes fast to the nock-earring-crinkle. Lacing round the mast is spliced to the nock-crinkle, and round the fore-side of the mast, backwards and forwards, and through each cringle on the fore-leech of the fail, making fast to the tack at the lower end.

*Tack* sets up with a lanard reeved through the tack-crinkle in the foot of the fail, and through an eye-bolt in the deck.

*Sheet* reeves through a block on the horse, at the fore part of the taffrail; then through the block that hooks to the thimble, in the clue of the fail; again through the block on the horse, and belays to a cleat on the side.

*Brails*, 41, (*Plate IV. fig. 2.*) throat, middle, and peek, reeve through their respective blocks on the yard or gaff, and make fast to cringles on the after-leech of the fail on each side. The throat-brails lead down by the mast, and the middle brails lead down to the after-mizen-shroud on each side, and the peek-brails to a cleat on each quarter.

*Fancy-line*, 42, (*Plate IV. fig. 2.*) has two spans, with a thimble seized in the bight, and a thimble seized in each end; one thimble reeves upon the throat-brail, the other on the middle brail, on each side the fail. The fancy-line reeves through blocks lashed at the peek end, and each end bends to the thimble in the bight of the span on each side. When the mizen is set, the brails are hauled up by the fancy-line, that they may be slack, and not girt the lee-side of the fail.

### *Rigging and Bending the Topfails.*

The *fore-topfail*, 6, (*Plate IV. fig. 2.*) is swayed up into the top by the topfail-haliards, that make fast to slings round the middle of the fail, and then laid in the fore part of the top fair for bending.

*Sheets*, 44, (*Plate IV. fig. 2.*) are passed through the fore part of the clue of the fail, and itopt with an overhand-knot. They reeve through the shoulder-block at the lower yard, then through the quarter-block, and come down before the mast; reeve through the sheave-holes in the bitts, and there belay.

*Clue-lines*, 45, (*Plate IV. fig. 2.*) The straps of the blocks are passed through the clues of the fail, and brought round the clue to the fore part, and securely seized. The clue-lines are passed the same as the clue-garnets of the courses, and sometimes have no block, but bend to the clue of the fail.

*Bow-lines*, 46, (*Plate IV. fig. 2.*) reeve through the blocks at the bowsprit-cap. The outer part reeves on the lower bow-line bridle with a thimble, as the main-course. The leading-part comes in upon the forecastle, and belays to the topfail-sheet-bitts.

*Bunt-lines*, 47, (*Plate IV. fig. 2.*) reeve through the block upon the yard, lead down on the fore-side of the fail, and clinch to the cringles in the foot-rope. The leading-part reeves through a single block, lashed close under the topmast cross-trees, leads down through the square hole in the top, and belays to the shrouds.

*Reef-tackle-pendants*, 48, (*Plate IV. fig. 2.*) reeve through the upper sheave in the sifter-block in the topmast-shrouds,

then through the sheave-hole in the yard-arm, and clinch to the reef-crinkle in the leech-rope of the fail.

*Reef-earings* reeve through their bights in each reef-crinkle, and are itopt to the next cringles and the head of the fail, till used.

*Spilling-lines* have two legs, which are each made fast with a timber-hitch round the quarters of the topfail-yard, then lead down on the aftside, return upwards under the foot of the fail, and reeve through a block on the fore-side, lashed to the tye-block on the yard, then lead down upon deck abaft the mast.

*Life-lines, earings, rope-bands, and points*, as the fore-course.

*Gaskets*.—The yard-arm gasket reeves with an eye round the yard-arm, within the cleats. Quarter-gaskets reeve as the above, between the yard-arm and slings. Bunt-gaskets have two legs, and lash to the yard with an eye on each side the tye-block, and fasten thereto, when the fail is hauled up in the bunt.

The *MAIN-TOPSAIL*, 2, (*Plate IV. fig. 2.*) is swayed up into the top, as the fore-topfail.

*Sheets*, 51, *clue-lines*, 52, *bunt-lines*, 53, *reef-tackle pendants*, 54, *earings, rope-bands, points, and gaskets*, as the fore-topfail.

*Bow-lines* reeve through blocks lashed round the fore-mast-head, close under the cap; the outer part reeves on the lower bowline-bridle with a thimble, as the fore-topfail. The leading-part comes down through the square hole of the cap, reeves through a sheave-hole in the bitts upon the forecastle, and there belays.

The *MIZEN-TOPSAIL*, 10, (*Plate IV. fig. 2.*) in large ships, is swayed as the foregoing.

*Sheets*, 56, *clue-lines*, 57, *bunt-lines*, 58, *reef-tackle pendants*, 59, *earings, rope-bands, points, and gaskets*, as the fore-topfail.

*Bow-lines*, 60, (*Plate IV. fig. 2.*) bend to the fail as the fore-topfail, and reeve through a single block, seized to the main-shrouds on the opposite side near the futtock-staff; then lead down through a seizing-truck to the quarter-deck, and belay to the rack at the shrouds.

### *Rigging and Bending the Top-gallant Sails.*

The *FORE-TOP-GALLANT-SAIL*, 7, (*Plate IV. fig. 2.*) is either swayed up to the topmast cross-trees by the clue-lines, or bent to the yard upon deck. It is hauled out to the yard-arm by earings, and bends or laces to the yard, as before observed.

*Sheets*, 62, and *clue-lines*, 63, are bent to the clues of the fail, and lead down upon deck, as the fore-topfail.

*Bunt-lines*, 64, reeve through a small block, seized to the top-gallant-mast-head; then through a thimble seized to the tye, close down upon the yard, and bend, with legs, to cringles in the foot of the fail. The leading-part comes down into the top.

*Bow-lines*, 65, (*Plate IV. fig. 2.*) reeve through the thimbles at the jib-boom-end, and fasten to the fail as the topfail, only with a toggle, to cast off the bow-line readily for fending the yard down. The leading-part comes down the forecastle, and belays to a pin in the hook over the bowsprit.

The jack-block is strapped with a seizing-eye, through which reeves a short piece of rope, with an eye spliced in one end, and a double walnut-knot made at the end, called a button and loop, which encircles the mast, by thrusting the knot through the eye, and is tried up and down the mast by the top-gallant-tye, which bends through the eye

## RIGGING.

of the strap. It is used for fending the top-gallant-yards up or down. When the yard is swayed up, the top-rope reeves through the jack-block, and makes fast with a hitch round the yard in the slings, then flopt at the outer quarter to the eye-bolt in the yard-arm. When lowered, the same, except the flop at the eye-bolt. The rigging is taken off or put on by the men at the mast-head, when the yards are swayed up or lowered down.

The MAIN-TOP-GALLANT-SAIL, 3, (*Plate IV. fig. 2.*) rigs and bends as the former. Bow-lines, 67, reeve through the sheave-holes in the after-ends of the fore-top-mast cross-trees, and lead down upon deck. *Sheets*, 68, *clue-lines*, 69, *bunt-lines*, 70, *Plate II. fig. 2.*

The MIZEN-TOP-GALLANT-SAIL, 11, rigs and bends as the former. Bow-lines, 72, reeve through the sheave-holes in the after-end of the main-topmast cross-trees.

### *Rigging and Bending the Royals.*

*Royals*, fore, 8, main, 4, and mizen, 12, (*Plate IV. fig. 2.*) are set flying; the clues lashed to the top-gallant yard-arms.

When royal masts are used, the royals rig similar to top-gallant sails.

### *Rigging and Bending the Jib and Stay-sails.*

*Jib*, 7, (*Plate IV. fig. 1.*) bends to its stay with hank and seizings.

*Stay*, 57, reeves through the upper sheave of the cheek-block at the fore-topmast-head, from aft on the starboard side, then through the hanks, and clinches to the traveller on the boom; a double block is then turned in the lower end, and its fall reeves through it; and a single block, lashed to the after-end of the fore-mast trestle-trees, leads down upon deck, and belays to the bitts abaft the fore-mast.

*Haliards*, 58, reeve through the lower sheave of the cheek-block at the fore-topmast-head, from aft on the starboard side, and bend to the head of the fail. The leading-part leads abaft the top to the aft part of the forecastle. Large ships have a single block turned into the lower end of the haliards, and a whip-fall; the standing-part makes fast into the side.

*Sheets*, 59.—The bight is bent to the clue of the fail, and a single block turned in each inner end, that reeves a whip-fall. The standing-part makes into the side, and the leading-part leads in upon the forecastle, and belays to a timber-head, or a cleat before the shrouds on each side.

*Downhauler*, 60, reeves through a small block lashed to the traveller, then leads upwards through the hanks, and bends to the head of the jib. The leading-part leads in upon the forecastle.

*Outbauler* reeves through a sheave-hole at the outer end of the jib-boom, and clinches to the span-shackle of the traveller. The inner end has a double block turned in, which reeves with its fall to a single block, hooked to an eye-bolt in the fore part of the bowsprit-cap, and the fall leads in on the forecastle.

*Inbauler* reeves through a small block lashed on the traveller. The standing-part makes fast to an eye-bolt in the side of the bowsprit-cap, and the leading-part comes in upon the forecastle.

The FORE-TOPMAST-STAYSAIL, 6, (*Plate IV. fig. 2.*) bends to its stay with hanks and seizings. *Stay*, 62, reeves through the hanks, then makes fast with a running-eye round the bowsprit, between the collars and the spritfail-yard; then reeves through the upper sheave of the cheek-block, at the fore-topmast-head, on the larboard side; the

lower end has a double block turned in, and reeves with its fall to a single block lashed at the after-end of the fore-mast trestle-trees, leads upon deck, and belays to the bitts abaft the fore-mast.

*Haliards*, 63, reeve through the lower sheave of the cheek-block at the fore-topmast-head, on the larboard side, and bend to the head of the fail. The leading-part leads down abaft the top to the after-part of the forecastle, and belays to a cleat in the side.

*Sheets*, 64.—The bight is bent to the clue of the fail, and leads through a single block, lashed to an eye-bolt on each side of the forecastle.

*Downhauler*, 65, reeves through a small block that lashes at the tack of the fail, then leads up through the hanks, and bends to the head of the fail; and the leading-part comes in upon the forecastle.

*Outbauler* reeves through a block lashed at the outer end of the bowsprit; the standing-part makes fast to the tack of the fail, and the leading-part comes in upon the forecastle.

FORE-STAYSAIL, 5, (*Plate IV. fig. 1.*) bends to the preventer-stay with hanks and seizings.

*Haliards*, 67, reeve through a single block bent to the head of the fail. The standing-part makes fast round the head of the fore-mast; and the leading-part reeves through a block lashed to the rigging under the top, and leads down abaft the mast.

*Sheets*, 68, are doubled, and the bight put through the clue of the fail; and a single block spliced in each end. The standing-part of the fall is made fast round a timber-head on the forecastle or eye-bolt, and the leading-part comes in through a block made fast to the said eye-bolt.

*Tack*, 69, bends to the tack of the fail, and lashes the tack of the fail to the stay near the heart.

*Downhauler*, 70, reeves up through the hanks, bends to the head of the fail, and leads in upon the forecastle through a single block lashed near the tack.

MAIN-STAYSAIL, 1, (*Plate IV. fig. 1.*) is seldom bent in ships but at sea, though commonly in brigs. It bends to the main-stay-fail stay with hanks and seizings.

*Stay*, 72, has its upper end clinched round the main-mast-head above the rigging, and the lower end set up with a luff-tackle round the foremast.

*Haliards*, 73, reeve through a single block lashed to the head of the fail. The standing-part makes fast at the main-mast-head, and the leading-part reeves through a block lashed to the rigging under the top, and leads down abaft the mast: a double block is turned in to the end, and connected, by its fall, to a single block, hooked to an eye-bolt in the side abaft the mast.

*Sheets*, 74, are doubled, the bight is put through the clue of the fail, and the ends through the bight. A block is spliced into each end, and the standing-part of each fall makes fast on its respective side at the fore part of the quarter-deck, and the leading-part through a snatch-block. Sometimes a luff-tackle is clapt on to bowse the sheets aft.

*Tacks*, 75, bend to the tack of the fail, and lash the tack of the fail to the foremast, or the bitts abaft it.

*Downhauler*, 76, reeves up through the hanks, bends to the head of the fail, and belays to the main-top bow-line bitts.

MAIN-TOPMAST-STAYSAIL, 2, (*Plate IV. fig. 1.*) bends to the main-topmast preventer-stay with hanks and seizings.

*Haliards*, 78, reeve from the aftside through the cheek-block at the main-topmast-head on the larboard side, come

## RIGGING.

down and bend to the head of the fail. The leading-part reeves through a block in the side.

*Sheets*, 79, are doubled, the bight is put through the clue of the fail, and the ends through the bight. A block is spliced in each end, and the standing-part of each fall makes fast on its respective side to the boat-skid beam next before the quarter-deck, and the leading-parts reeve through a block on the gunwale abaft the gangway, and belays to a pin in the boat-skid beam.

*Tacks*, 80, are doubled, the bight is put through the tack of the fail, and the ends reeve through the bight, and lead through a thimble seized to the lower shrouds on each side; they lead down and belay to a shroud-cleat.

*Brails*, 81, reeve through blocks lashed to the strap of the main-bowline-block, and through blocks seized to the topmast preventer-stay, at the cat-harpins on each side, and then make fast on each side the fail to a cringle on the after-leech.

*Sheets*, 82, are doubled, the bight is put through the clue of the fail, and the ends through the bight. A block is spliced in each end, and the standing-part of each fall is made fast on its respective side to the boat-skid beam next the quarter-deck, and the leading-part reeves through a block on the gunwale on each side abaft the gangway.

*Tacks*, 83, are doubled, the bight is put through the tack of the fail, and the ends through the bight, and lead through a thimble seized on the lower shrouds on each side; they then lead down and belay to one of the shroud-cleats.

**MIDDLE-STAYSAIL**, 3, (*Plate IV. fig. 1.*) bends to the middle-stay-fail-stay with hanks and seizings.

*Stay*, 85. The standing-part reeves through the hanks, and makes fast to a thimble seized in a strap or grommet made fast round the fore-topmast-head, below the parral. The leading-part reeves through the upper sheave-hole at the main-topmast-head: a double block is then turned into the end, and connects by its fall with a single block, that lashes to the main-treble-trees, and the fall by which it is set up leads upon deck abaft the mast.

*Haliards*, 86, reeve through the lower sheave of the cheek-block at the main-topmast-head, and bend to the head of the fail; the other end leads upon deck abaft the mast.

*Sheets*, 87, are doubled, the bight is put through the clue of the fail, and the ends through the bight, and lead down through a block on each side near the gangway.

*Tacks*, 88, are doubled, the bight is put through the tack of the fail, and the ends through the bight, and each end through a thimble seized in the fore-topmast-shrouds, and belays in the top.

*Downhauler*, 89, reeves through a single block seized to the stay at the neck of the fail, then leads up through the hanks, and bends to the head of the fail, and the lower end comes down upon deck abaft the mast.

*Tricing-line* clinches to the grommet round the fore-topmast, and reeves through a block under the fore-topmast-cross-trees, and leads down into the top.

**MAIN-TOP-GALLANT-STAYSAIL**, 4, (*Plate IV. fig. 1.*) bends to the stay, or main-top-gallant-stay, in small ships, with hanks and seizings.

*Stay*, 91. The upper end splices into the top-gallant-stay below the rigging, and the lower end reeves through a thimble seized to the fore-topmast-cross-trees, leading down into the top.

*Haliards*, 92, reeve through a sheave-hole above the hounds of the main-top-gallant-mast, and bend to the head of the fail; the leading-part comes down upon deck, and belays to the bits abaft the main-mast.

*Sheets*, 92, and *tacks*, 93, as the middle stay-fail.

*Downhauler*, 94, reeves up through the hanks, and bends to the head of the fail; and the leading-part comes upon deck abaft the fore-mast.

**MIZEN-STAYSAIL**, 8, (*Plate IV. fig. 1.*) bends to the mizen-stay-fail stay with hanks and seizings.

*Stay*, 96, hitches round the head of the mizen-mast, then reeves through a thimble seized in a collar lashed round the main-mast, and sets up with a laniard through a thimble turned in to the stay, and an eye-bolt in the deck abaft the mast.

*Haliards*, 97, reeve through a block at the head of the fail, the standing-part makes fast round the mizen-mast-head, and the leading-part reeves through a block lashed to the treble-trees, and through a block in the side at the deck.

*Sheets*, 98, bend to the clue of the fail with a long and short leg, having a thimble spliced in the latter. The long leg reeves through a block in the side, and through the thimble in the short leg, and belays to the rack at the side.

*Tack*, 99, splices to the tack of the fail, and lashes it to an eye-bolt in the deck abaft the mizen-mast.

*Downhauler*, 100, reeves through a block made fast to the collar of the stay, then upwards through the hanks, and bends to the head of the fail, and belays to the fore-brace bits.

*Brails*, 101, reeve through blocks lashed on each side the collar, then through thimbles in a strap put through the fail, and make fast to a cringle on the after-leech. The leading-part belays a-breast of the quarter-deck.

**MIZEN-TOPMAST-STAYSAIL**, 9, (*Plate IV. fig. 1.*) bends to the mizen-topmast-stay with hanks and seizings.

*Haliards*, 103, reeve through the sheave-hole in the topmast above the rigging, or through a block lashed round the mast-head; one end bends to the head of the fail, the lower end leads down upon deck abaft the mast.

*Sheets*, 104, are doubled, the bight put through the clue of the fail, and the ends through the bight; then through a thimble seized in the mizen-shrouds on each side, and lead down and belay to a pin in the shroud-rack.

*Tacks*, 105, are doubled, the bight put through the tack of the fail, and the ends through the bight, then through a thimble seized to the main-topmast-shrouds on each side, and lead down and belay in the top.

*Downhauler*, 106, reeves up through the hanks, and bends to the head of the fail; the lower end leads down upon deck, and belays at the fore part of the quarter-deck.

**MIZEN-TOP-GALLANT-STAYSAIL**, 10, (*Plate IV. fig. 1.*) bends to the mizen-top-gallant-stay with hanks and seizings.

*Haliard*, 108, reeves through the sheave-hole above its top-gallant-mast hounds; one end bends to the head of the fail, the lower end leads down upon deck abaft the mast.

*Sheets*, 109, are doubled, the bight put through the clue of the fail, and the ends through the bight, and lead down upon deck through a thimble seized in the mizen-shrouds, on each side near the cat-harpins, and belay to a pin in the shroud-rack.

*Tacks*, 110, bend to the tack of the fail as the sheets, and lead down into the top through a thimble seized in the main-topmast-shrouds on each side.

*Downhauler*, 111, reeves up through the hanks, and bends to the head of the fail, the lower end comes into the main-top, and belays to the top-rail.

*Rigging and Bending the Studding-Sails.*

*Studding-sails* bend their yards at the head with rope-bands, the same as other square sails.

*Lower studding-sails*, main, 15, (*Plate IV. fig. 2.*) *Outer haliards*, 61, reeve through a span-block hitched round the lower cap, and through a block at the lower yard-arm or boom-iron, and bend between the cleats of the studding-fail-yard; the other end leads down upon deck.

*Inner haliards*, 62, bend to the upper inner cringle on the head of the fail, then reeve through a tail-block made fast round the quarter of the lower yard, then through another block made fast round the yard near the mast, and lead down upon deck.

*Sheets*, 63, are doubled, the bight is put over, and the ends through the inner clue on the foot of the fail; one leads forward, and the other aft.

*Fore-studding-fail*, 18, (*Plate IV. fig. 2.*) sets flying, or with a boom at the foot. If flying, the foot of the fail spreads on a yard, that rigs with a span clinched round each yard-arm. A guy is bent to an eye that is crossed in the middle of the span, and leads aft through a block lashed to the main-chains, leads in through a port, and belays round a cleat in the waist. The fail thus rigged has no tacks. Booms rig as follow: the hook in the inner end hooks to an eye-bolt between the fore-chains and cat-head, and the hook of the main-studding-fail-boom in an eye of an iron strap on the fore part of the main channel; the end is confined down with a lashing to the chain-plates; the inner end of the fore-boom is confined down with a tackle, made fast round the inner end of the boom, and the lower block is hooked to an eye-bolt in the wale; the guy clinches round the middle of the boom, reeves through a block lashed round the spritfail-yard, and leads in upon the forecastle.

*TOPMAST-STUDDING-SAILS*, Main, 16, Fore, 19, (*Pl. IV. fig. 2.*) *Haliards*, 90, 91, reeve through a block in the span round the topmast-head, under the cap, and through the jewel-block, at the outer end of the top-fail-yard-arm, and bend to the topmast-studding-fail-yard; the other end leads down upon deck, and belays to the bits next the mast.

*Sheets* are doubled, the bight is put through the inner clue, and the ends through the bight. The after-sheet, 92, of the fore-topmast-studding-fail leads in abaft the fore-shrouds, and the fore-sheet, 93, leads in upon the forecastle. The after-sheet, 94, of the main-topmast-studding-fail leads down to the quarter-deck, and the fore-sheet, 95, upon the gangway.

*Tacks*, 73, bend to the outer clue of the fail, reeve through a block lashed to the outer end of the boom, and lead aft through a block at the gangway. Tack, 74, of the main-topmast-studding-fail leads in upon the after-part of the quarter-deck through a block lashed upon the quarter.

*Downhauler*, 75, reeves through a block lashed to the outer clue of the fail, and through a thimble on the outer keech: it is then made fast to the topmast-studding-fail-yard, just within the earing, and leads into the waist.

*The Booms*, 76, 77, are run out by the tackles. The strap of the double-block makes fast through a hole in the keel of the boom, and the outer block to the boom-iron, and the fall leads along the yard. On the middle of the boom is fastened a selvagee, or a strap with a thimble, to which is hooked the top-burton-tackle, to support the boom in the middle.

*TOP-GALLANT-STUDDING-SAILS*; fore, 20, main, 17,

(*Plate IV. fig. 2.*) *Haliard* reeves through a block seized round the head of the top-gallant-mast, above the hoards or rigging, then through the jewel-block, strap with a thimble through an eye-bolt at the ends of the top-gallant-yards, and bends to the top-gallant-studding-fail-yard; the other end leads down the mast into the top.

*Sheets*, 80, are doubled, the bight is put through the lower inner clue of the fail, and the ends through the bight; one end leads forward, and makes fast to the quarter of the top-fail-yard, and the other end leads into the top, and belays to the topmast-shrouds.

*Tacks*, 81, bend to the outer clue of the fail, and reeve through a thimble in a strap round the outer end of the topmast-studding-fail-boom; and in merchant ships that have no boom, through a thimble in a strap round the outer yard-arm of the topmast-studding-fail. The fore-top-gallant-studding-fail-tack leads aft to the main-chains, and the main leads to the quarter-piece.

*Downhauler*, 82, makes fast to the outer yard-arm within the earing, and leads down into the top.

*Rigging and Bending the Spritfail-Course.*

The spritfail-course, 13, (*Plate IV. fig. 2.*) bends to its yard as the fore-course.

*Sheets*, double, 84, reeve through a block seized to the clue of the fail; the standing-part clinches to an eye-bolt in the bow, and the leading-part comes in on the forecastle.

*Sheets*, single, bend to the clue of the fail, and lead in-board.

*Clue-lines*, 85, reeve through the blocks upon the yard, and bend or reeve through a block at the clue of the fail, and lead in upon the forecastle.

*Bunt-lines*, double, 86, reeve through the block on the yard, and clinch to the cringles at the foot of the fail, and lead in upon the forecastle.

*Bunt-lines*, single, reeve through a block in the slings of the yard, and clinch with legs to the cringles in the foot of the fail, and lead in upon the forecastle.

*Rigging and Bending the Spritfail-Topfail.*

The spritfail-topfail, 14, (*Plate IV. fig. 2.*) bends to the yard with lacing and earings.

*Sheets*, 88, reeve through the sheet-block at the spritfail-yard-arm, and hook to the clue of the fail, and lead in upon the forecastle, through a block lashed on each side of the bowsprit.

*Clue-lines*, 89, the same as the spritfail.

*Rigging and Bending the Driver or Spanker-fail, 11, Plate IV. fig. 1.*

This fail is only used occasionally, and is bent or hoisted in a temporary manner, thus; it is made fast at the peek, 113, and nock, 114, with an earing, as the mizen, and makes fast to the yard and gaff with four or five pairs of haliards, that reeve through blocks made fast with tails round the yard and gaff, one end of the haliard being bent to the head of the fail. The throat-haliards, 115, reeve with a double and single block: the former is made fast round the mast-head, and the latter hooks to the nock-cringles on the fail.

*Sheet*, 116, reeves through a block or sheave-hole at the outer end of the boom, and bends to the clue of the fail; a luff-tackle is cat's-pawed to the other end of the sheet; the inner block hooks to the taffarel, and the fall leads in upon the quarter-deck. When this fail is bent to the mast, yard, or gaff, instead of the mizen, it bends exactly the same, only the foot of the fail is extended on the boom, as above.

Tack,

**Tack**, 117, is set tight with a luff-tackle, that hooks to the cringle in the tack of the sail, and to an eye-bolt in the throat of the boom.

**Downhauler**, 118, reeves through a block made fast to the middle of the driver-yard, and leads down to the taffarel.

### *Rigging of Snows, Brigs, &c.*

A *Snow* has her sails and rigging on the fore and main-mast, similar to those on the same mast in a ship. The braces of the yards on the main-mast lead forward. The tryfail abaft the main-mast bends to the tryfail-mast, similar to the mizen of a ship.

Vessels in the navy resembling snows have a rope-horse, that sets up abaft the main-mast, with dead-eyes and a lanard, to an eye-bolt in the deck, to which the tryfail is bent by hanks and seizings, similar to the tryfail of a snow.

**Brigs**.—The rigging of a brig differs little from the fore and main-mast of a ship; the braces of yards on the main-mast lead forward. The after-main-throw is served from the mast-head to the dead-eye, to prevent its being chafed by the main-boom and gaff. The after-backstay is fitted with a tackle, that it may be slackened when the main-sail jibes, or is bowfed forward by the boom-pendant and tackle.

**BOOM-TOPPING-LIFT** is taken up on the starboard side, and reeved through an iron-bound block, hooked to the upper eye-bolt on the aftside of the main-mast-head, then leads down and reeves through a block at the after-end of the boom. The standing-part clinches round the mast-head, or hooks to an eye-bolt near the block; the leading-part comes down and has a double block spliced or turned in, that connects by its fall to a single block that hooks to an eye-bolt in the after-part of the channel. Sometimes it has the addition of a runner.

**Main-sheet** reeves through a double block, strapped round the boom within the taffarel, and through another double block, strapped round the horse inside the taffarel, and belays to a large cleat, or the pin in the sheet-block of small vessels. Large vessels sometimes have a treble block on the horse.

**Tack-tackle** has the double block fastened to the tack of the sail, and connects with its fall to a single block hooked to an eye-bolt in the deck.

**Guy-pendants** have a hook and thimble, that hook in a thimble of a strap on the boom, just without the main-sheet-block. In the inner end of the pendant, is a thimble or long-eye spliced, to which is hooked a luff-tackle, which is hooked to an eye-bolt in the side before the mast, and the fall leads in-board.

**GAFF-TOPPING-LIFT** rigs similar to the boom above, only it has a span upon the gaff, and the block at the mast-head hooks to the eye-bolt, next below the boom-topping-lift; and the

**Haliard** connects it to an eye-bolt in the deck or side, the same as the boom.

**Inner tye** is similar to the above, and hooks to an eye-bolt in the jaws of the gaff, then reeves through an iron-bound block, that hooks to an eye-bolt in the mast-head below the above. It has a double block spliced or turned in to the lower end, and sets up by the haliards, the lower block hooking to an eye-bolt on the opposite side to the tye above.

**Peek downhauler** reeves through a small block, strapped with a thimble to the eye-bolt at the outer end of the gaff, and belays round a cleat under the boom.

**Throat-downhauler** reeves through a block at the nock of the sail, and leads down the aftside of the mast.

**MAIN-SAIL** bends at the head to the gaff with lacing and earings, and is seized to the hoops round the mast, through the holes in the fore-leech.

**Throat-downhauler**.—The double block hooks to an eye-bolt under the throat of the gaff, that connects by its fall to a single block hooked to the thimble, seized in the bight of a strap round the mast under the boom-fiddle.

**Sheet-rope** splices in the clue of the sail, and reeves through a sheave-hole in the boom; and a thimble is turned in to the inner end, to which hooks the sheet or luff-tackle, and the inner block to a strap round the boom near the jaws. When the sail is hove out, it is lashed with an earing through the clue, and an eye-bolt in the boom-end.

**Tricing-line** reeves through a small block made fast to an eye-bolt in the throat of the gaff; one end splices to the tack of the sail, the other end leads down upon deck, and belays to a cleat on the mast.

### *Rigging of Cutters or Vessels with one Mast.*

The different articles before the mast rig similar to ships, and the shrouds, boom, &c. as the brigs.

**GAFF-TOPSAIL** laces to a small gaff at the head.

**Haliards** reeve through a sheave-hole at the top-gallant-mast-head, and bend to the inner quarter of the gaff; the leading-part comes down upon deck.

**Topping-lift** reeves through a sheave-hole, or small block, seized to the top-gallant-head, then through a thimble or small block seized at the outer end of the gaff; the standing-part clinches round the top-gallant-mast-head above the sheave-hole, and the leading-part comes down upon deck.

**Sheet** reeves through a thimble seized at the peek of the main-sail, and bends to the clue of the sail, and leads down upon deck.

**Tack** makes fast to the tack of the sail, a little above the rigging.

**Saveall topfail**.—The clues lash near the lift-block of the cross-jack-yard.

**Haliards** bend to the earings of the sail, and reeve through a block on each quarter of the topfail-yard, and lead down upon deck.

**RINGTAIL-SAIL** bends to a small yard on the head, and is hoisted by the peek downhauler, abaft the main-sail. The foot is expanded on a small boom, or spar, lashed to the outer end of the main-boom.

**WATER-SAIL** bends on the head to a small yard.

**Haliards** reeve through a small block lashed under the outer end of the main-boom, and make fast to the middle of the yard, and the leading-part belays round a cleat on the taffarel.

**Sheets** make fast to the clues of the sail, and lead in over the quarters.

**MIZEN** is set on a small mast over the stern. If a square-sail, it bends to a yard at the head, and is hoisted by a haliard reeved through a sheave-hole at its mast-head, and is spread by sheets at the foot. If a sprit-sail, its fore-leech bends to the mast with grommets, and is spread or peeked with a sprit, and the foot hauls aft by the sheet to a small boom.

**RIGGING**, *Serving the*. See **RIGGING**.

**RIGHT**, **RECTUM**, in *Logic* and *Ethics*.

In this sense the word stands opposed to *wrong*, *erroneous*, *false*, &c.

**RIGHT**, in *Geometry*, something that lies evenly, without inclining or bending one way or another.

Thus, a *right line* is that whose several points all tend the same way, or which lies evenly between its extremes.

In this sense, *right* signifies as much as *straight*, and it stands opposed to *curved* or *crooked*.

**RIGHT Angle.** See **ANGLE**.

In this sense, the word *right* stands opposed to *oblique*.

**RIGHT-Angled** is understood of a figure, when its sides are at right angles, or stand perpendicularly one upon another.

This sometimes holds in all the angles of the figure, as in squares and rectangles; sometimes only in part, as in right-angled triangles.

**RIGHT Cone.** See **CONE**.

**RIGHT-Lined Angl.** See **ANGLE**.

**RIGHT Sine.** See **SINE**. The word here stands contradistinguished to *versed*.

**RIGHT Ascension, in Astronomy.** See **ASCENSION**.

**RIGHT Ascension, Angle of.** See **ANGLE**.

**RIGHT Ascension, Parallax of.** See **PARALLAX**.

**RIGHT Descension.** See **DESCENSION**.

**RIGHT Descension, Parallax of.** See **PARALLAX**.

**RIGHT Sphere** is that where the equator cuts the horizon at right angles: or, that in which the poles are in the horizon, and the equator in the zenith.

Such is the position of the sphere with regard to those who live directly under the equator. The consequences of which position are, that they have no latitude, nor elevation of the pole. They can see nearly both poles of the world; all the stars rise, culminate, and set, with them; and the sun always rises and descends at right angles to their horizon, and makes their days and nights equal.

In a right sphere the horizon is a meridian; and, if the sphere be supposed to revolve, all the meridians successively become horizons, one after another.

**RIGHT Circle, in the Stereographical Projection of the Sphere,** is a circle at right angles to the plane of projection, or that which passes through the eye. See **PROJECTION**.

**RIGHT Sailing** is when a voyage is performed on some one of the four cardinal points.

If a ship sail under the meridian, that is, on the north or south points, she varies not in longitude at all, but only changes the latitude, and that just so much as the number of degrees she has run.

If a ship sail under the equinoctial upon the very east or west points, she alters not her latitude at all, but only changes the longitude, and that just so much as the number of degrees she hath run.

If she sail directly east or west, under any parallel, she there also altereth not her latitude, but only the longitude; yet that not according to the number of degrees of the great circle she hath sailed in, as under the equinoctial, but more according as the parallel is remoter from the equinoctial towards the pole. For the less any parallel is, the greater is the difference of longitude.

**RIGHT, Jus, in Law,** signifies not only a property, for which a writ of right lies, but also any title or claim, either by virtue of a condition, mortgage, or the like, for which no action is given by law, but only an entry.

Such are *jus proprietatis*, a right of property; *jus possessionis*, a right of possession; and *jus proprietatis et possessionis*, a right both of property and possession.

This last was formerly called *jus duplicatum*. As if a man be disseised of an acre of land, the disseisee has *jus proprietatis*; the disseisor hath *jus possessionis*; and, if the disseisee release to the disseisor, he hath *jus proprietatis et possessionis*. See **JUS**.

**RIGHT, Hereditary.** See **HEREDITARY**.

**RIGHT, Petition of.** See **PETITION**.

**RIGHT, Pretensed.** See **PRETENSED**.

**RIGHT of Reformation.** See **REFORMATION**.

**RIGHT, Writ of.** See **WRIT** and **RECTO**.

**RIGHT in Court.** See **RECTUS in Curia**.

**RIGHT Distillation.** See **DISTILLATION**.

**RIGHTING, in Sea Language,** denotes the act of restoring a ship to her upright position, after she has been laid on a careen. This is generally the natural effect of casting loose the careening pulleys, by which she had been drawn down. But it is sometimes necessary to apply mechanical powers to right the ship in such a situation; and the principal of these are the relieving tackles.

A ship is said also to right at sea, when the masts with her masts erected, after having been prest down on one side by the effort of her sails, or a heavy squall of wind. Falconer.

**RIGHTING, when expressed of the helm,** implies the replacing it amidships, after it has been put over to the side in tacking or otherwise.

**RIGHTS, Bill of, in Law,** is a declaration, delivered by the lords and commons to the prince and princess of Orange, February, 13 1688; and afterwards enacted in parliament, when they became king and queen. This declaration sets forth, that king James II. did, by the assistance of divers evil counsellors, endeavour to subvert the laws and liberties of this kingdom, by exercising a power of dispensing with and suspending of laws; by levying money for the use of the crown, by pretence of prerogative, without consent of parliament; by prosecuting those who petitioned the king, and discouraging petitions; by raising and keeping a standing army, in time of peace; by violating the freedom of election of members to serve in parliament; by violent prosecutions in the court of king's bench; and causing partial and corrupt jurors to be returned on trials, excessive bail to be taken, excessive fines to be imposed, and cruel punishments inflicted; all which were declared to be illegal. And the declaration concludes in these remarkable words, "And they do claim, demand, and insist upon, all and singular the premises, as their undoubted rights and liberties." And the act of parliament itself (1 W. & M. stat. 2. cap. 2.) recognizes "all and singular the rights and liberties asserted and claimed in the said declaration to be the true, ancient, and indubitable rights of the people of this kingdom."

**RIGIACUM, in Ancient Geography,** a town of Belgic Gaul, and capital of the Atrebatii. Ptolemy.

**RIGID MARBLE.** See **MARBLE**.

**RIGIDITY, among Philosophers,** a brittle hardness; or that kind of hardness supposed to arise from the mutual indentation of the component particles within one another.

Rigidity is opposed to ductility, malleability, &c.

**RIGLAND, in Geography,** a town of Germany, in the margraviate of Anspach; 7 miles N. of Anspach.

**RIGLET.** See **REGLET**.

**RIGNAC, in Geography,** a town of France, in the department of the Aveyron, and chief place of a canton, in the district of Rodes; 12 miles W.N.W. of Rodes. The place contains 851, and the canton 7182 inhabitants, on a territory of 202½ kilometres, in 16 communes.

**RIGNEY, a town of France,** in the department of the Dômb; 10 miles N.E. of Befançon.

**RIGNEY le Seron, a town of France,** in the department of the Aube; 6 miles N.W. of Ervy. N. lat. 48° 12'. E. long. 3° 43'.

**RIGNY, a town of France,** in the department of the Indre and Loire; 6 miles N.N.E. of Chiou.

**RIGO, a small island in the West Indies,** near the N.W. coast of Porto Rico.

**RIGODUNUM, in Ancient Geography,** a town of Britain,

tain, in the country of the Brigantes, placed by Camden and Baxter at Ribchester in Lancashire; but Horisley prefers Manchester or Warrington. See RIBCHESTER.

RIGOLL, or REGALS, a kind of musical instrument, consisting of several sticks bound together, only separated by beads. It makes a tolerable harmony, being well struck with a ball at the end of a stick.

Such is the account which Graffineau gives of this instrument.

Skinner, upon the authority of an old English dictionary, represents it as a clavichord, or clarichord; possibly founding his opinion on the nature of the office of the tuner of the regals, who still subsists in the establishment of the king's chapel at St. James's, and whose business is to keep the organ of the chapel royal in tune; and not knowing that such wind instruments as the organ need frequent tuning, as well as the clavichord and other stringed instruments.

Sir Henry Spelman derives the word *rigol* from the Italian *rigabello*, a musical instrument, anciently used in churches instead of the organ.

Walther, in his description of the regal, makes it to be a reed-work in an organ, with metal and also wooden pipes, and bellows, adapted to it. And he adds, that the name of it is supposed to be owing to its having been presented by the inventor to some king.

From an account of the regal, used in Germany, and other parts of Europe, it appears to consist of pipes and keys on one side, and the bellows and wind-chest on the other.

We may add, that lord Bacon (Nat. Hist. cent. ii. § 102.) distinguishes between the regal and organ, in a manner which shews them to be instruments of the same class. Upon the whole there is reason to conclude, that the *regal*, or *rigol*, was a pneumatic, and not a stringed instrument.

Mersennus relates that the Flemings invented an instrument, *les regales de bois*, consisting of seventeen cylindrical pieces of wood, decreasing gradually in length, so as to produce a succession of tones and semitones in the diatonic series, which had keys, and was played on as a spinnet; the hint of which, he says, was taken from an instrument in use among the Turks, consisting of twelve wooden cylinders, of different lengths, strung together, which, being suspended, and struck with a stick, having a ball at the end, produced music. Hawkins's Hist. Mus. vol. ii. p. 449. See REGAL.

RIGOMAGUS, in *Geography*, a town of Italy, in Liguria, at a small distance N. of Aſta.

RIGOR, in *Medicine*, a *shivering*, or the slight convulsive tremors, attended by a sensation of cold, which occur either from actual exposure to cold, or from that condition of the body which usually precedes a paroxysm of fever, or which, it should rather be said, constitutes one of the first symptoms of a febrile paroxysm. (See FEVER.) There is often no absolute diminution of the heat in the body, when this sensation of cold, and even actual shivering, with a disposition to sit near a fire, or to be loaded with blankets, occur. It arises, therefore, from some peculiar affection of the brain and nervous system, and not from actual deficiency of heat. This is farther proved by the circumstance, that a similar tremor, or *rigor*, is capable of being temporarily excited by certain impressions upon the sensorium; as by certain sights, or even thoughts, that excite horror; whence, indeed, the word *horror* is applied by medical writers in nearly the same sense with *rigor*.

Rigor, or chilliness, precedes or commences the attack of almost all febrile and inflammatory diseases; whence the vulgar, mistaking the first symptom for the cause, ascribe all these diseases to the agency of *cold*, the operation of

which they conceive to have been accomplished at the time when the *rigor* occurred. It takes place at the beginning of quinsey, pleurisy, peripneumony, and all the organic inflammations; at the commencement of almost all fevers; and at each such successive paroxysm or even exacerbation of intermittent, remittent, and hectic fevers: it constitutes the most striking feature, indeed, of the intermittent fever, which is hence called the *ague* by the common people, in contradistinction from the *fever*, or hot fit, which ensues. The tremor and clattering of the teeth are often so great, indeed, in the cold fit of an ague, as to shake the bed and its furniture about the patient. It made even Cæsar tremble.

“ He had a fever when he was in Spain,  
And, when the fit was on him, I did mark  
How he did shake: 'tis true, this god did shake.”  
Shakspeare.

The rigor is a symptom still more notorious in pathology, as having been the foundation of Dr. Cullen's whole theory of fever. That physician maintained, that the rigor, or *cold fit*, having been produced by the sedative influence of the common causes of fever on the brain, became itself the cause of the succeeding *hot* and *sweating* stages, by rousing the heart and arteries to greater actions, in order to throw back the load of blood into the extreme vessels, which had been driven to the centre by the constriction of the latter, while the *rigor* lasted. The reader will find this doctrine stated, and refuted, under the article FEVER, and the head *Cullenian Theory*. It is not difficult to shew, respecting this, as well as the vulgar opinion, that the *rigor*, like the heat, and the sweating, is one in the chain of *effects*, and not a *cause* of the phenomena which ensue. But it would be equally difficult to explain the immediate cause of any of them.

RIGOSA, in *Geography*, a town of Italy, in the department of the Serio; 3 miles N.N.W. of Bergamo.

RIGOURISTS, in *Ecclesiastical History*. See JANSENISM.

RIGUSA, in *Ancient Geography*, a town of Spain, in the Tarragonensis, belonging to the Carpetani. Ptolemy.

RIK, in *Geography*, a town of Persia, in the province of Irak; 12 miles N. of Ispahan.

RIKEBACH, a town of Germany, in the county of Bregentz; 7 miles S.S.E. of Bregentz.

RIKIKES, a town of Thibet; 35 miles S. of Deuprag.

RIL, a town of Africa, in Darfur; 60 miles S.S.E. of Cobbé.

RILANDA, a town of Sweden, in the province of Upland; 28 miles N.E. of Stockholm.

RILEY, JOHN, in *Biography*, a portrait painter, and the best which England had produced prior to sir Joshua Reynolds. He was born in London in 1646. After the death of Lely he obtained very considerable esteem and employment. He painted the portraits of king Charles II., James II. and his queen, and was appointed by James state-painter. His style is composed from Vandyke and Lely, and his execution is free and masterly, and bears an air of originality. He died in 1691, at the age of 45.

RILL, or RIVULET. See RIVER.

RILL, in *Agriculture*, a small runlet of water, mostly rising on the sides of small hills or declivities. In many situations they may be converted to useful purposes in husbandry, such as the irrigation of pasture or meadow lands that lie below their levels; the supplying of grass grounds with water, for the purposes of live-stock; and the afford-

ing it to towns and villages, in dry or other situations where it is scarce. See IRRIGATION, WATERING of *Land*, and the following article.

RILLS, *Artificial*, such as have been formed or made by means of art. It has been remarked, that the practice of constructing rivulets of this sort for supplying water is peculiar to a few districts of this country, as Yorkshire and west Devonshire, in the latter of which they have been made use of time immemorial in bringing what, in the simple language of the district, is termed "pot-water" to the farm-houses, and the hamlets of cottages in upland situations; an excellent expedient, which is supposed applicable in many other parts of the island, but which, except in the case of Yorkshire, has hitherto been confined to that extreme part of the country.

And in forming these sorts of rills in their original district, it is observed by Mr. Marshall, that one which supplies the house with water, also a drinking-pool near the yard, and in the natural course of it conveying it through a straw yard, a trough is placed across it for the use of the yard cattle; and which has, likewise, been for a vast length of time led over some grass land, which lies below the yards, on the principle of the float and drain. But that although this rill is seldom, if ever, dried up, leading it along the sides of the valley, through upland inclosures, which are destitute of water for stock, and their value of course thereby much depreciated, does not appear to have been thought of. In the course of the summer of 1792, being desirous to know if this rill could be carried through an intended suite of yards on the side of the valley, he took the level, and found not only that object to be attainable, but also that it might be led with ease into two waterless fields which lie above these yards; and, through them, into four or five more (equally in want of water for stock) situated beyond them. It is added that, in ascertaining these facts, he made use of a mason's long level inverted, a plummet-hole being previously cut in the head of the standard; the crown of which being set upon the ground, the arms of the level were steadied by rods in the horizontal position; and a carpenter's rule held across another rod, set up, at as great a distance as a clear sight would admit of, and at a height upon the staff equal to the height of the level. Finding this a most simple and perfect instrument, but difficult to adjust, by reason of its instability, he has since had a *frame-level* made on the same principle; namely, with a straight edge, or top rail, answering to the base-board of the long level, with a broad piece falling down from the middle of it, answering to the standard; and with two end-pieces or legs, to supersede the use of the rods, together with a bottom rail, eight or nine inches from the ground, and with diagonal braces to keep the whole firm, and prevent the middle or plumb-line from getting out of the square with the straight edge of the top rail; which is seven or eight feet long, and the height about four feet. He thinks that half a rod long, and a quarter of a rod high, are eligible dimensions when great accuracy is required. But a shorter length, as one-third of a rod, is more handy. And, as an improvement of the rule and rod, he has contrived a *cross-staff*; namely, a slip of thin deal, about five feet and a half long, with a cross-piece about two feet long and three inches wide, fixed in the edge of it, at the exact height of the level; the top of the staff rising twelve or eighteen inches above the upper edge of the cross-piece, that the hand of the person who holds it up may not interfere with the view. This cross-piece should be of white wood, as deal, or be painted white, that it may be more distinctly seen at a distance. With this implement the flowing level may be well ascertained.

And it is observed that, in order to ascertain the proper fall of a rill of this intention, he previously took the running level of the ancient floating *lead* of the meadow, and finding its fall irregular, he took it in two places where the variations were greatest. In the first, the fall was twenty-seven inches in one hundred and ten feet; which is nearly one inch, or one foot of fall to fifty inches, or fifty feet, in length. In this part the current is in a degree rapid; the fall much too great for the general intention. The fall in one hundred and ten feet of the other part is barely six inches; which is only one measure of perpendicular height to two hundred and twenty of horizontal length. But in this part the motion is too sluggish; the surface of the water is nearly smooth; barely dimpling; no ripple or agitation appears. The fall is evidently too little for a water course, in which there is not a constant stream. He has therefore fixed upon one measure in a hundred, as the proper fall of a water-course, into which water is occasionally thrown for the purposes of watering lands, filling drinking-pools, cisterns, and other similar purposes. And in order to adjust the level to this descent, he measured one hundred feet in length, and having nicely ascertained the *dead level*, he depressed the range of the top bar one foot below the upper edge of the cross-piece of the staff, and, while in that position, he marked the situation of the plumb-line on the face of the level, the plummet-hole being made wide for this purpose; thus fixing the flowing level. And with this descent, he has traced a line from an intended reservoir, and from point to point, through the fields of one side of the farm, and finds that it reaches, even with this descent, within every field; and that three-fourths, or a larger proportion, of the surface are capable of being floated from this intended pool. With the view of seeing the actual motion of water falling one in a hundred, he has had fifty yards of the upper end of the line opened, and finds the current fully sufficient; a lively rippling stream, more active, perhaps, than is necessary. But the leakage being the less the quicker the water moves, it may, he thinks, be safely concluded that one foot of fall in a hundred feet length is nearly the proper degree that is required.

And in the same case he has, by the same means, also found that, from a similar reservoir formed near the source of the rill, water might be conveyed to every field, and almost every acre of the opposite side of the farm, which is a matter of great consequence. It is suggested, that the uses of these reservoirs will be those of having in readiness, during the summer months, when the rill is weak, a body of water to throw into drinking-pools, cisterns, &c.; a weak current turned into a dry trench is absorbed by its perforations and fissures, for some time, at least, after it is turned in; whereas a body of water, rushing quickly along it, not only in part escapes absorption, but tends to fill up the leaks; and, in winter, these reservoirs will be useful in scouring the trenches, and in hoarding up bodies of water for the purpose of irrigation, or other similar uses. In the setting out of these rills, he has laid the head or upper end of each, from two to three feet below the intended surfaces of their respective reservoirs, when full. Hence, by the means of a portcullis flood-gate, a body of water two or three feet deep, and the whole extent of the surfaces of the basons, may be poured into the rills, faster or slower, as may be requisite. And in a subsequent minute it is stated, that difficulties were met with in conducting a rill through an open grove of trees, but which were overcome in the following manner; having, by means of the frame level and cross, ascertained the general descent, or flowing level, through the whole extent of the grove; and having, in this

operation, gained a general idea of the requisite direction of the rill, by means of stakes placed at the several stations of the cross-staff, wherever clear views could be caught through the openings between the trees, the intermediate spaces between the stakes were traced by the eye, so as to endeavour to follow the natural level of the ground, without forming abrupt bends in the channel: parrying between the two. And that the supposed line being thus set out, the surface of the ground was cleared two or three feet wide on either side of it, from leaves and other incumbrances, and the top soil removed for manure; thus making a hollow pathway through the grove, four or five feet wide. The next operation was to level this pathway, which was likewise done by the eye, from stake to stake; paring off the protuberances, and casting or wheeling them into the hollows to fill them up. Then in order to come at the true line, and to render the flowing level perfectly uniform, a narrow pathlet, the width of the spade, was formed on the upper side of the broad pathway. This pathlet was formed with the frame level in hand, sinking trenches in the still protuberating parts, and raising banklets in the hollows; thus fixing the exact flowing level at each level's length, and, at the same time, forming the face or lower side of it, in such manner as to ease the bends, and give a smooth flowing line to the rill or rivulet of the water. And further, in order to bring the business of forming the bed of the rill to a certainty, and thereby to render any further superintendance unnecessary, yet to prevent error in the execution, he formed a gauge for the labourers to work by; which consisted of a board, forming the segment of a circle; the chord or greatest length being three feet, the greatest depth twelve inches. This gives the dimensions of the bed of the rill. To keep the bottom of it exactly true to the flowing level, so that the current stream may be perfectly uniform, it is fixed under a mason's short level; the end of one of the arms projecting three or four inches beyond one end of the gauge. And the trench being sunk to nearly its proper depth, by the eye kept on the adjusted margin, the projecting end of the level is placed on the same marginal guide, and the plummet-line being brought to the perpendicular, (and the base of the level of course rendered horizontal,) the bottom of the trench is finished with certainty.

Upon having the water turned into the upper part of the trench thus formed, by two common labourers, who never before, perhaps, took a level in their hands, the current was found not only desirable as to descent, but perfectly uniform, without alteration. And hence the practicability and certainty of this method of forming the channels of rills, as well as the eligibility of one measure in a hundred, for the descent or fall, are fully ascertained. It is observed that the above dimensions are the most proper for the part passing under trees, as being liable to fill up, by leaves and small twigs; but in open land, liable to be trodden by cattle, four feet in width, and eight inches deep is better, the lower side being made broad and flatly convex to prevent treading in, being turfed over with the fods removed.

But in respect to the Yorkshire rills, the same writer remarks that the heights of the northern margin have neither springs nor rivulets (some very few instances excepted), nor any other natural waters than the brooks which wind at the bottom of the deep vallies that divide them, and the rivulets which generally run at the feet of the precipices that terminate them. That formerly these brooks and rivulets were the only resources which the villages that are scattered on these heights had for water, both for the use of cattle and for domestic purposes. But that in process of time wells were sunk, but they are of such a depth as to make the

labour of raising the water little less than that of fetching it from a moderate distance. Of course that this kind of natural necessity has led to an expedient which, though not new in principle, is perhaps entirely so in simplicity of execution, and might be practised with great advantage in many similar situations. For as the moorland mountains rise with generally an easy ascent, from the beds of the rivulets last-mentioned, to a height much exceeding that of the hills to be watered, frequently abounding with springs almost to their highest swells, these springs are collected and conducted by a narrow channel down the slope of the mountain sides, and along the face of the precipice, until the summit be gained; the waters being thence conveyed to the place or places desired. It is stated that, in planning an artificial rill, a level, and some little knowledge of the country, are, as has been seen, the requisite guides. The surveyor begins at the place to which the water is required to be brought, and ascertains the lowest part of the brink of the precipice from which water can be conducted. The face of the precipice is traced in like manner; and, if necessary, the ascent of the moorland hills, until springs, or their natural rills, can be commanded. And that if his level bring him to the bottom of the steep soon enough to catch the rivulet which runs at its foot, the work is readily completed. If not, he goes above its highest bend, generally to the head or highest part of the valley (between the heights and the moorlands), and winds along the side of the opposite swell to some more elevated source. And if, when he arrives on the moorland hills (or, by an observation from the top of the precipice,) he finds that nature does not furnish the requisite quantity of water high enough to give the necessary fall, the work is, of course, impracticable.

But in regard to the manner of executing an artificial rill in this part, an opening shallow channel, of a width proportioned to the quantity of water to be conducted, is the main operation. In making stagnant pools, it has been found that much art is necessary to make them retentive, but in forming the bed of a rill no such art is requisite. It is the nature of running waters to render the surface on which they run firm and retentive. Sand is, he believes, the chief material used in forming the channels of these rills; and this only in places where an open rock or other porous stratum is crossed. But much depends on the quantity of fall and the quantity of water. If the fall be but little, and the quantity of water at the source be such as not to admit of much waste, great care is requisite in forming the bed of the rill. The fall is therefore regulated in a great degree by the quality of the ground. On good ground the channel is nearly level. Over faulty ground the water runs with a current for the double purpose of getting quickly over it, and rendering its channel more retentive. The circumstances from which injuries are produced in these rills are leaves in autumn and snows in winter. To remove the obstructions which these not unfrequently cause, and to repair such breaches as time will always make in the work of art, a superintendant is necessary to every artificial rill.

And it is observed that the rill of Kirby moor-side is, he believes, the largest, and was the first which was brought upon these heights. This rill was brought to the villages of Gillimore and Fadmore near forty years ago; and has been extended to Kirby about thirty years, by Joseph Ford, a self-taught engineer of great ingenuity and some judgment; a man to whom the country owes much. Since the introduction of this, several others have been raised; and some few unsuccessful attempts have been made; the channel was, in one instance, (that of Newton,) extended a considerable way before the impracticability of completing it

was discovered; a piece of misconduct which nothing but a want of accuracy in the use of the level can lead to. The miscarriage, in this case, was not owing to a want of elevation in the source, but to a depression of the channel at the foot of the steep; the head of the valley (if such it may be called) being lower than the top of the precipice at the given point. This shews the necessity of tracing the entire channel with sufficient accuracy before any other expence is incurred. The mode of doing which has been shewn above.

It is likewise further stated, that in the case of Kirby the channel is raised somewhat by a bridge-like mound of earth thrown across the crown of the valley. And that the same mound serves the purpose of conducting another rill across the same difficult pass; from whence the Kirby rill takes an eastward, the rill of Welburn (applied principally to the watering of pasture grounds) a westward direction.

Also in regard to the expence, it is stated that the first cost of the Kirby rill was not altogether one hundred pounds. The distance about ten miles, watering (besides the town of Kirby) two villages and a line of cultivated waterless upland country about four miles in length. Besides the first cost, which was raised by subscription, a superintendent had ten pounds a-year for keeping it in repair and free from obstructions; which yearly salary is paid by the contributions of the persons benefited; each being rated agreeably to the estimated benefit received.

It may be noticed, that from the vast advantages that have been derived from the construction of these sorts of rivulets, in these few cases of upland dry situations, the attention of the land proprietor and farmer in other districts where there is a prevalent scarcity of water, either for domestic purposes, or the use of cattle stock, should be directed to the execution of them, on such cheap and beneficial plans as may be the most convenient in the particular situations. See POND.

These kinds of rills should, in all cases where they are capable of it, be turned to the purpose of watering land, as well as the uses noticed above.

RILLE, in *Geography*, a town of France, in the department of the Maine and Loire; 9 miles E. of Baugé. —Also, a river of France, which runs into the Seine, six miles below Quilbœuf.

RILLY, a town of France, in the department of the Marne; 6 miles S. of Reims.

RILSK, a town of Russia, in the government of Kursk, on the Sem; 52 miles W.S.W. of Kursk. N. lat.  $51^{\circ} 30'$ . E. long.  $34^{\circ} 54'$ .

RIM, in a watch or clock, the circumference or circular part of a wheel.

RIMS, in *Ship Building*, compass-pieces of timber, which form the quarter-galleries between the stools.

RIMS, a skirting of elm-board round the upper side of ships' tops.

RIM, a cast-iron frame, in which the dropping-palls of the capstan traverses, and palls, or counteracts the efforts of the capstan.

RIMA literally denotes a fissure or chink. See FISSURE, and RHAGADES.

Hence, it is applied to several parts of the body, that bear a resemblance thereto; as *rima pudendi*, fissura magna, the same with vulva: and *rima laryngis*, the aperture of the larynx, called the *glottis*.

RIMA is also used for a narrow aperture of a small cavity under the fornix, opening into the infundibulum; called also the third ventricle of the brain.

RIMA, in *Geography*, a river of Hungary, which runs into the Theysse, near Bolgar.

RIMAC, a river of Peru, which passes by Lima, in a valley to which it gives name, on which Lima is built, and runs into the Pacific ocean, S. lat.  $12^{\circ}$ .

RIMAGIONE, a town of Genoa; 5 miles S.S.W. of Spezza.

RIMASZOMBAT, a town of Hungary; 14 miles E.S.E. of Altfol.

RIMBA, a province of Benguela, in Africa, on the banks of the Morano.

RIMBACH, a town of the duchy of Wurzburg; 3 miles S. of Volkach.

RIMBU, a town of Thibet; 71 miles W. of Lassa. N. lat.  $30^{\circ} 35'$ . E. long.  $89^{\circ} 50'$ .

RIME, in *Poetry*. See RHYME.

RIME, in *Rural Economy*, a sort of hoary or white frosty appearance, sometimes on the ground in the autumnal winter and early spring mornings.

RIMENANT, in *Geography*, a town of France, in the department of the Two Nethes; two miles E. of Malines.

RIMERS are moveable bars to support the sluices and over-falls in opening-weirs.

RIMFORSA, in *Geography*, a town of Sweden, in West Gothland; 17 miles S. of Linköping.

RIMINI, a sea-port town of Italy, capital of the department of the Rubicon, late in the Romagna; formerly situated on the sea, but the sea has for some centuries receded to a distance. The harbour on the river Marechia, on which the city is built, is now so choaked up with sand, as scarcely to admit of small barks. This city was once very flourishing, but besides other calamities which have befallen it, it suffered extremely from an earthquake in 1671. It is the see of a bishop, suffragan of Ravenna. This is the ancient Ariminum, the first town of which Cæsar took possession, after passing the Rubicon. In the market-place there is a kind of stone pedestal, with an inscription, declaring, that upon it Cæsar had stood and harangued his army; but the authenticity of this is not ascertained to the satisfaction of antiquaries. Besides this suggestion of doubtful antiquity, here is a triumphal arch, erected to the emperor Augustus, and the remains of an amphitheatre. This city is said to have been built 500 years earlier than Rome itself, and to have been made a colony in the year of Rome 483. It derived its name from the river Arminus, which washed its walls, and separated the Via Flaminia from the Via Æmilia. Two councils were held here, one of orthodox bishops, in the year 358, and another in the following year, of Arian prelates. Vitalien, governor of the city for the emperor Justinian, defended it against Vitiges, king of the Goths, with such vigour, as to oblige the Goths to raise the siege. Some time after it became subject to the Lombards; but when their last king, Didier, was conquered and taken prisoner by Charles the Great, Rimini returned to the allegiance of the western emperors. The liberality of Otho III. conferred the dominion of it on the Malatesta family: at last the Venetians gained possession of it, and by a treaty with pope Julius II. gave it to the holy see. The harbour at Rimini was formerly famous, being covered with marble, and of such extent, as to contain a considerable fleet; but its mouth being filled up with sand, Sigismond Pandolfo Malatesta destroyed it, and with the marble stones, raised out of its ruins, built the Franciscan church, which is the finest in Rimini; 57 miles S.E. of Bologna. N. lat.  $44^{\circ} 4'$ . E. long.  $12^{\circ} 38'$ .

RIMIS, a small island in the Baltic, near the coast of Pomerania. N. lat.  $54^{\circ} 11'$ . E. long.  $13^{\circ} 26'$ .

RIMNIK. See RIBNIK.

RIMONT, a town of France, in the department of the Arriege; 8 miles W.N.W. of Tarascon.

RIN, in *Rural Economy*, a provincial word used to signify brine.

RINÆUS, in *Anatomy*. See NASALIS.

RINALDI, ODERIC, in *Biography*, a learned Italian ecclesiastical historian in the 17th century, was a native of Treviso, and entered the establishment belonging to the priests of the congregation of the Oratory at Rome, of which Baronius had been a member. After the death of that cardinal, Rinaldi undertook the laborious task of continuing his "Ecclesiastical Annals," from the year 1198, with which the work of Baronius terminated, to the year 1564, when the council of Trent had been dissolved. It abounds with many curious and valuable documents, taken from the archives at the Vatican, and other collections. It consists of ten large volumes in folio, which made their appearance in Rome at different periods, from 1646 to 1677. Rinaldi published a sufficiently copious abridgment, in Italian, of the whole annals, compiled both by Baronius and himself.

RINALDO DI CAPUA, an eminent Neapolitan composer, who flourished in the middle of the last century, and whose story is somewhat singular.

He was the natural son of a person of very high rank in that country, and at first only learned music as an accomplishment; but being left by his father with only a small fortune, which was soon dissipated, he was forced to make it his profession. He was but seventeen when he composed his first opera at Vienna.

In the course of a long life, Rinaldo experienced various vicissitudes of fortune, sometimes in vogue, sometimes neglected. However, finding old age coming on, he collected together his principal works, such as had been produced in the zenith of his fortune and fancy, thinking these would be a resource in distressful times; those times arrived; various misfortunes had happened to him and his family; when, behold! this resource, this *sole* resource, the accumulated produce of his pen, had by a graceless son been sold for walle paper!

This composer, whose productions were, during many years, the delight of all Europe, in 1770 was reduced at Rome to the utmost indigence. Diogenes the Cynic was never more meanly clad through choice, than Rinaldo through necessity: a patched coat, and stockings that wanted to be patched or darned! We, having often received great pleasure from his works, courted his acquaintance and conversation, which was very lively and intelligent; but though a good-natured man, his opinions were very singular and severe on his brother composers.

He thought they, at that time, "had nothing left within the reach of their invention to entitle them to reputation for novelty, but the refuse of thousands, which had been often tried and rejected, either as impracticable or displeasing. The only chance which a composer has for introducing new modulation in songs, was in a short second part, (every serious song then ended with a *da capo*,) in order to fright the hearer back to the first, to which it serves as a foil, by making it comparatively beautiful." He included himself in the censure, and frankly confessed, that though he had written full as much as his neighbours, yet out of all his works, perhaps not above *one* new melody could be found, which had

not been wire-drawn in different keys, and different measures, a thousand and a thousand times.

We subscribed to these opinions at the time, till we heard Haydn's quartets and symphonies, Paesello's vocal compositions, and Mozart's latter works, vocal and instrumental.

Rinaldo censured, with great severity, the noise and tumult of instruments in modern songs;—what would he say now to our double-drums and tromboni?

Rinaldo had the reputation at Rome of being the inventor of accompanied recitatives; but in searching for old compositions in the archives of San Girolamo della Carita, at Rome, we found an oratorio of Alessandro Scarlatti, which was composed at the latter end of the 17th century, before Rinaldo di Capua was born, and in which there are *accompanied recitatives*. But he did not, himself, pretend to the invention; all that he claimed was the being among the first who introduced ritornels, or interstitial symphonies, in recitatives of strong passion and distress, which express or imitate what it would be ridiculous for the voice to attempt. There have been since many fine scenes of this kind in the works of Jomelli, Perez, Galuppi, Sarti, Piccini, Sacchini, and Paesello.

Rinaldo seems to have been a successful composer from 1737 to 1758. His first serious opera at Rome was "Il Ciro Riconosciuto," in 1737; and "Adriano in Siria," the last, in 1758.

A very fine air from "Vologeso" was sung by Monticelli in England, and printed by Walsh among the favourite songs in the opera of Gianguir,—"Nell' orror di notte oscura,"—to which we refer as a specimen of his serious style. Indeed the whole scene in that opera, beginning by the accompanied recitative, "Berenice, ove sei?" and terminated by the air, "Ombra che pallida," is admirable, and a proof to what perfection dramatic music was brought in Italy fifty or sixty years ago; and the curious will do well to procure a copy of this scene whenever they have an opportunity.

It has been said, perhaps with some truth, that the science of this composer was not equal to his genius; for being educated as a dilettante, he probably did not submit to all the drudgery of dry study, which one intended for the profession of music is obliged to undergo.

RINAR, a word used by the chemists, to express filings of any thing.

RINAUR, in *Geography*, a town of Hindoostan, in Mysore; 25 miles E. of Chinna Balabarum.

RINCADROLEAN POINT, a cape on the W. coast of Ireland, in the county of Kerry. N. lat.  $52^{\circ} 44'$ . W. long.  $10^{\circ} 13'$ .

RIND, a skin of any fruit that may be cut off, or pared. The outer coat of the chestnut, set with prickles, is particularly called the *urchin-like rind*.

RIND is also used for the inner bark of trees; or that soft, whitish, juicy substance, adhering immediately to the wood.

Through this it is that the sap has been supposed to return from the extremities of the branches to the root: the vessels hereof are by some also supposed to do the office of arteries; whence Mr. Bradley calls them *arterial vessels*. See PLANTS.

RIND, *Grafting in the*. See ENGRAFTING.

RIND-Gall, a damage a tree receives when young, so that the bark or rind grows in the inner substance of the tree.

RINDE, in *Geography*, a river of Hindoostan, which runs into the Jumna, 15 miles S.E. of Corah.

RINDERA, in *Botany*. See *CYNOGLOSSUM levigatum*, n. 14.

RINDGE, or RINGE, in *Geography*, a town of America, in the county of Cheshire, New Hampshire, situated on the Maffachuffett's line, about 80 miles W. of Portsmouth, and 70 N.W. of Boston. This town was incorporated in 1768, and contains 1226 inhabitants. This township has 13 ponds of water of different sizes, in which are perch, trout, eels, &c. It has also, towards the northern part, a mine of ochre of a Spanish brown. One half of the water of this town runs to the Merrimack, and the other to the Connecticut river.

RINDOMS, a town of Spain, in Catalonia; 11 miles N.W. of Tarragona.

RINDSAKER, a town of Norway; 60 miles N.N.E. of Christiania.

RINEKENBERG, a town of the duchy of Carinthia; 6 miles E. of Wolkenmarck.

RINEUS MARINUS, a name given by some botanical writers to the crithnum, or samphire, a sea-plant, used as a pickle.

RING, ANNULUS, a little moveable, put on the finger, either by way of ceremony, or of ornament.

The bishop's ring makes a part of the pontifical apparatus; and is esteemed a pledge of the spiritual marriage between the bishop and his church.

The episcopal ring is of a very ancient standing. The fourth council of Toledo, held in 633, appoints that a bishop condemned by one council, and found afterwards innocent by a second, shall be restored, by giving him the ring, staff, &c.

From bishops, the custom of the ring has passed to cardinals, who are to pay a very great sum, *pro jure annuli cardinalitii*.

RINGS, *Origin of*. Pliny (lib. xxxvii. cap. 1.) observes, that we are in the dark as to the person who first invented, or wore the ring; because what is said of Prometheus, as also of Midas's ring, are fables. The first people among whom we find the ring in use, are the Hebrews, (Gen. xxxviii.) where Judah, Jacob's son, gives Tamar his ring, or signet, as a pledge of his promise; but the ring appears to have been in use at the same time among the Egyptians, from Gen. xli. where Pharaoh puts his ring upon Joseph's hand, as a mark of the power he gave him. And in the first book of Kings, chap. xxi. Jezebel seals the warrant she sent for the killing of Naboth, with the king's ring.

The ancient Chaldeans, Babylonians, Persians, and Greeks, had likewise the use of the ring; as appears from several passages in Scripture, and from Quintus Curtius, who tells us, that Alexander sealed the letters he wrote into Europe with his own seal; and those in Asia with Darius's ring.

The Persians will have Guiamfeluld, the fourth king of the first race, to have first introduced the ring, for sealing his letters and other acts. The Greeks, Pliny thinks, knew nothing of the ring in the time of the Trojan war; the reason he gives is, that we find no mention of it in Homer, but that when letters, &c. were to be sent away, they were tied up, and the strings knotted.

The Sabines had rings in Romulus's time; and it is to them, probably, the practice first came from the Greeks; and from them that it passed to the Romans; though it was some time before it got footing there. Pliny cannot learn which of the kings of Rome first adopted it; but there are no signs of it in any of their statutes, before those of Numa and Servius Tullius. He adds, that it was also in use among the ancient Gauls and Britons.

RINGS, *Matter of Ancient*. There were some of one single metal, and others of a mixture, or two. For the iron and silver were frequently gilt; or at least the gold part was fixed within the iron, as appears from Artemidorus, lib. ii. cap. 5. The Romans were contented with iron rings a long time; and Pliny assures us, that Marius first wore a gold one in his third consulate, which was in the year of Rome 650. Sometimes the ring was iron, and the seal gold; sometimes it was hollow, and sometimes solid; sometimes the stone was engraven, and sometimes plain; and the graving sometimes was in relieve, and sometimes in creux: the last were called *gemmæ clypæ*; the former *gemmæ sculptura prominente*.

RING, *the manner of wearing the*, has been various. From Jeremiah, chap. xxii. it appears, that the Hebrews wore it on their right hand. Among the Romans, before they came to be adorned with stones, and while the graving was yet on the metal itself, every one wore them at pleasure, on what hand and finger he pleased. When stones came to be added, they wore them altogether on the left hand; and it would have been held an excessive foppery to have put them on the right.

Pliny says, they were at first worn on the fourth finger; then on the second or index; then on the little finger; and at last on all the fingers, excepting the middle one.

The Greeks wore them altogether on the fourth finger of the left hand, as we are informed by Aul. Gellius, lib. x. and the reason he gives for it is, that having found from anatomy, that this finger had a little nerve that went straight to the heart, they esteemed it the most honourable, by reason of this communication with that noble part. Pliny says, the Gauls and ancient Britons wore the ring on the middle finger.

At first they only wore a single ring, then one on each finger, and at length several on each finger. (Martial, lib. xi. epig. 60.) At last one on each joint of each finger. (Aristoph. in Nub. &c.) Their foppery at length arose to that pitch, that they had their weekly rings.

Juvenal, Sat. vii. speaks of *annuli semestres*; as also of winter and summer rings. But of all others, Lampridius, cap. 32. observes, that Heliogabalus carried the point farthest, who never wore the same ring, or the same shoe, twice.

Rings have been also worn in the nose, and as pendants in the ears. Bartholin has an express treatise, "De Annulis Narium," *Of Rings of the Nostrils*. St. Augustine assures us, it was in his time the fashion of the Moors; and Pietro della Valle observes the same of the modern orientals.

In effect, there is no part of the body where rings have not been worn. Several East India travellers affirm, that the natives now commonly wear them on their nose, lips, cheeks and chin. Ramusio tells us, that the ladies of Narsinguy, in the Levant, and Diodorus Siculus, lib. iii. that those of Ethiopia used to adorn their lips with iron rings.

As to the ears, the custom still obtains of wearing rings in them, both of men and women, almost all over the world. See PENDANT.

The Indians, particularly the Guzzarats, have worn rings on their feet. And when Peter Alvarez had his first audience of the king of Calicut, he found him all covered with stones set in rings, having bracelets and rings both on the hands and fingers, and even on the feet and toes.

Louis Bartome represents a king of Pegu as still more extravagant, having rings set with precious stones on every toe.

RINGS, *Use of*.—The ancients had three different kinds; the

the first served to distinguish conditions or quality. Pliny assures us, that the senators at first were not allowed to wear the gold ring, unless they had been ambassadors at some foreign court. Nor was it even allowed them to wear the gold ring which was given them in public, except on public occasions; at other times they wore an iron one. And those who had a triumph observed the same rules.

At length the senators and knights were allowed the common use of the gold ring; but Acron on Horace, lib. ii. sat. vii. observes, they could not do it unless it were given them by the prætor.

In after days the gold ring became the badge of the knights, the people wearing silver rings, and the slaves iron ones; though the gold ring was sometimes also allowed the people, and Severus granted it to his common soldiers. Augustus allowed it to the liberti or freedmen; and though Nero made a regulation to the contrary, yet it was soon set aside.

A second kind of rings comprehended the *annuli sponsalium*, wedding-rings. Some carry the origin of this custom as far back as the Hebrews, on the authority of a text in Exodus, xxxv. 22. Leo of Modena, however, maintains, that the ancient Hebrews did not use any nuptial ring. Selden, in his *Uxor. Ebraica*, lib. ii. chap. xiv. owns, that they gave a ring in the marriage, but that it was only in lieu of a piece of money of the same value which had used to have been given before. The Greeks and Romans did the same, and from them the Christians took it up very early, as appears from Tertullian, and in some ancient liturgies, where we find the form of blessing the nuptial ring.

The third kind of rings included those used as seals, called *cerographi* or *cirographi*; an account of which, see under the article SEAL.

Richard, bishop of Salisbury, in his Constitutions, anno 1217, forbids the putting of rush rings, or any the like matter, on women's fingers, in order to the debauching them more readily; and he insinuates the reason of his prohibition, that there were some people weak enough to believe, that what was thus done in jest was a real marriage.

De Breveil, in his *Antiquities of Paris*, says, it was an ancient custom to use a rush-ring in the nuptials of such as had had an affair together before their marriage.

RING, in *Angling*, an instrument intended to free the hook when accidentally entangled among weeds. See ANGLING.

RING, in *Astronomy*. The ring of Saturn is a thin, broad, opaque, circular arch, encompassing the body of that planet, like the horizon of an artificial globe, without touching it, and appearing double, when seen through a good telescope.

The discovery of it is owing to M. Huygens, who, after frequent observation of Saturn, with telescopes which magnified two or three times more than any that had been before made, perceived two lucid points, or ansæ, arising out from the body in a right line.

Hence, as in subsequent observations, he always found the same appearance, he concluded that Saturn was encompassed with a permanent ring; and accordingly produced his new system of Saturn in 1659.

However, Galileo first discovered that the figure of Saturn was not round. It appeared to him like a large globe between two small ones; and he announced this discovery in the year 1610. Prosecuting his observations till the year 1612, he was then surprised to find only the middle globe; but in process of time he again discovered the globes on each side, which appeared to change their form; sometimes appearing round, sometimes like an acorn, some-

times semicircular, then with horns towards the globe in the middle, and growing by degrees so long and wide as to encompass it, as it were, with an oval ring. Huygens, who, as we have said, completed the discovery, makes the space between the globe of Saturn and the ring equal to, or rather bigger than, the breadth of the ring; and the greatest diameter of the ring, in proportion to that of the globe, as 9 to 4. But Mr. Pound, with an excellent micrometer, applied to the Huygenian telescope of 123 feet in length, determined this proportion to be as 7 to 3.

Mr. Whiston, in his "Memoirs of the Life of Dr. Clarke," informs us, that the doctor's father once saw a fixed star between the ring and the body of Saturn. M. Cassini, in 1675, observed upon the ring a dark elliptical line, dividing it, as it were, into two rings; the inner of which appeared brighter than the other. He also perceived a dark belt upon the planet, parallel to the greater axis of the ring. Mr. Hadley observed, that the outer part of the ring seemed narrower than the inner part, and that the dark line was fainter towards its upper edge; he also saw two belts, and observed the shadow of the ring upon Saturn. In October, 1714, when the plane of the ring very nearly passed through the earth, and was approaching it, M. Maraldi observed, that while the arms were decreasing, both in length and breadth, the eastern arm appeared a little larger than the other for three or four nights, and yet it vanished first; for after an interruption for two nights by clouds, he saw the western arm alone. This inequality of the ring made him suspect that it was not bounded by exactly parallel planes, and that it turned about its axis. In the sequel of this article we shall give the substance of Dr. Herschel's observations, which, on account of his accuracy as an observer, and the superior excellence of his telescopes, are much more important than any others, as he has discovered many circumstances which had escaped all other observers.

This ring, seen from Saturn, appears like a large luminous arc in the heavens, as if it did not belong to the planet. When we see the ring most open, its shadow upon the planet is broadest; and from that time the shadow grows narrower, as the ring appears to do to us; until, by Saturn's annual motion, the sun comes to the plane of the ring, or even with its edge; which, being then directed towards us, becomes invisible, on account of its thinness.

The principal phenomena of Saturn's ring are familiarly illustrated by a view of *Plate XIX. Astronomy, fig. 14.* Let S be the sun, A B C D E F G H Saturn's orbit, and I K L M N O the earth's orbit. Both Saturn and the earth move according to the order of the letters; and when Saturn is at A, his ring is turned edgewise to the sun S, and he is then seen from the earth as if he had lost his ring, let the earth be in any part of the orbit whatever, except between N and O; for whilst it describes that space, Saturn is apparently so near the sun as to be hid in his beams. As Saturn goes from A to C, his ring appears more and more open to the earth; at C the ring appears most open of all; and seems to grow narrower and narrower as Saturn goes from C to E; and when he comes to E, the ring is again turned edgewise both to the sun and earth: and as neither of its sides is illuminated, it is invisible to us, because its edge is too thin to be perceptible; and Saturn appears again as if he had lost his ring. But as he goes from E to G, his ring opens more and more to our view on the under side; and seems just as open at G as it was at C; and may be seen in the nighttime from the earth in any part of its orbit, except about M, when the sun hides the planet from our view. As  
Saturn

Saturn goes from G to A, his ring turns more and more edgewise to us, and therefore it seems to grow narrower and narrower; and at A it disappears as before. Hence, while Saturn goes from A to E, the sun shines on the upper side of his ring, and the under side is dark; and whilst he goes from E to A, the sun shines on the under side of his ring, and the upper side is dark. The ring disappears twice in every annual revolution of Saturn, *viz.* when he is in 19th degree of Pices and of Virgo, and when Saturn is in the middle between these points, or in the 19th degree either of Gemini or of Sagittarius, his ring appears most open to us; and then its longest diameter is to its shortest, as 9 to 4. Ferguson's *Astr. lect.* 204.

Dr. Herschel (*Phil. Transf.* for 1790, vol. lxxx. pt. 1.) observes, that the black disc, or belt, upon the ring of Saturn, which we have already mentioned, is not in the middle of its breadth; and that the ring is not subdivided by many such lines, as some astronomers have represented; but there is one single, dark, considerably broad line, belt, or zone, which he has constantly found on the north side of the ring. (See *Plate XIX. Astronomy, fig. 15.*) "Since the year 1774, to the present time," as Dr. Herschel says (*Phil. Transf.* for 1792, vol. lxxxii. pt. 1.) "I can find only four observations where any other black division of the ring is mentioned, than the one which I have constantly observed: these were all in June, 1780." As this dark belt is subject to no change, it is probably owing, as the doctor remarks, to some permanent construction of the surface of the ring. This belt cannot be the shadow of a chain of mountains, since it is visible all round on the ring; for at the ends of the axis there could be no shade visible on account of the direction of the sun's illumination, which would be in the line of the chain; and the same argument will hold against any caverns or concavities. It is, moreover, fully evident, that this dark zone is contained between two concentric circles, as all the phenomena answer to the projection of such a zone. Thus in *fig. 16*, we may see that the zone is continued all round the ring, with a gradual decrease of breadth towards the middle, answering to the appearance of a narrow circular plane, projected into an ellipsis. The matter of the ring is undoubtedly no less solid than the planet itself; and it is observed to cast a strong shadow upon the planet. The light of the ring is also generally brighter than that of the planet; for the ring appears sufficiently bright when the telescope affords scarcely light enough for Saturn. From many repeated observations, which we cannot here detail, Dr. Herschel establishes the fact of the extreme thinness of the ring. He farther observes, that there may be a refraction through a very rare atmosphere on the two planes of the ring, by which the satellite may be elevated and depressed, so as to become visible on both sides of the ring, even though the ring should be equal in thickness to the diameter of the smallest satellite, which may amount to 1000 miles. From a series of observations upon luminous points of this ring, (*Phil. Transf.* vol. lxxx. pt. 2.) he has discovered that it has a rotation about its axis, in  $10^h 32' 15''$ .

The ring is invisible when its plane passes through the sun, or the earth, or between them: in the first case, the sun shines only upon its edge, which is too thin to reflect sufficient light to render it visible; in the second case, the edge only being opposed to us, it is not visible, for the same reason; in the third case, the dark side of the ring is exposed to us, and therefore the edge being the only luminous part which is towards the earth, it is invisible, for the same reason as before. Observers have differed ten or twelve days as to the time of its becoming invisible, owing to the

difference of the telescopes, and of the state of the atmosphere. The disappearance of the ring seems to occur only with the telescopes in common use among astronomers; for Dr. Herschel, with his large telescopes, has been able to see it in every situation. He thinks the edge of the ring is not flat, but spherical, or spheroidal. He observes, that the ring was seen in his telescope, when we were turned towards the unenlightened side; so that he either saw the light reflected from the edge, or else the reflection of the light of Saturn upon the dark side of the ring, as we sometimes see the dark part of the moon. He cannot, however, say which of the two might be the case; especially as there are very strong reasons for thinking, that the edge of the ring is of such a nature as not to reflect much light. M. de la Lande thinks, that the ring is just visible, with the best telescopes in common use, when the sun is elevated  $3'$  above its plane, or three days before its plane passes through the sun; and when the earth is elevated  $2' 20''$  above the plane, or one day from the earth's passing it. In the *Phil. Transf.* for 1790, Dr. Herschel ventured to suggest a suspicion that the ring was divided; this conjecture was strengthened by subsequent observations, after he had an opportunity of seeing both sides of the ring. His reasons are these; 1st, the black division upon the northern side of the ring, is in the same place, of the same breadth, and at the same distance from the outer edge, that it always appeared upon the northern side; 2dly, with his seven-foot reflector and an excellent speculum, he saw the division in the ring, and the open space between the ring and the body, equally dark, and of the same colour with the heavens about the planet; 3dly, the black division is equally broad on each of the rings. From these observations, Dr. Herschel thinks himself authorized to say, that Saturn has two concentric rings, situated in one plane, which is probably not much inclined to the equator of the planet. The dimensions of the ring are in the following proportions, as nearly as they could be ascertained.

	Parts.
Inside diameter of the smaller ring	5900
Outside diameter	7510
Inside diameter of the largest ring	7740
Outside diameter	8300
Breadth of the inner ring	805
Breadth of the outer ring	280
Breadth of the space between the rings	115

M. de la Place, in the "*Mem. de l'Acad. at Paris*," supposes that the ring may have many divisions; but Dr. Herschel remarks, that no observations will justify this supposition.

From the mean of a great many measures of the diameter of the larger ring, Dr. Herschel makes it  $46''.677$ , at the mean distance of Saturn. Hence, its diameter : the diameter of the earth :: 25.8914 : 1. From the above proportion, therefore, the diameter of the ring must be upwards of 204,883 miles; and the distance of the two rings 2839 miles.

The ring being a circle, appears elliptical from its oblique position; and it appears most open, when Saturn is  $90^\circ$  from the nodes of the ring, upon the orbit of Saturn; or when Saturn's longitude is about  $2^\circ 17'$ , and  $5^\circ 17'$ . In such a situation, the lesser axis is very nearly equal to half the greater, when the observations are reduced to the sun; consequently the plane of the ring makes an angle of about  $30^\circ$  with the orbit of Saturn.

The breadth of the ring (as stated by Dr. Herschel, *Phil. Transf.* vol. xcvi. pt. 2. p. 467.) is to the space between the ring and the body of Saturn as about 5 to 4.

Kepler,
